MINUTES OF THE 45th GENERAL ASSEMBLY OF THE EUROPEAN ASSOCIATION FOR THE STUDY OF DIABETES

held in Messe Wien, Vienna, Austria on 1 October 2009

Present:	**Dr. U. Smith**	**(President)**
	Dr. G. Spinas	**(Honorary Treasurer)**
	Dr. M. Stumvoll	**(Honorary Secretary)**
	Dr. E. Gale	**(Editor-in-Chief, Diabetologia)**
	Dr. J. Nolan	**(Chair, PGESC)**
	Dr.V. Jörgens	**(Executive Director)**
	Dr. M. Grüsser	**(Vice Director)**
	and 51 members	

The President welcomed everyone to the 45th General Assembly.

1. MINUTES 44th GENERAL ASSEMBLY 2008

Since there were no comments, the minutes were approved unanimously and officially signed as a correct record.

2. REPORTS

a) President

The President said he had given his report during the Presidential Address on Wednesday 30 September 2009.

b) Honorary Treasurer

Dr. Spinas reported that the accounts were in a healthy state. He said the main income came from the membership and registration fees. A transfer of 4 million Euros had been made to the Foundation.

Dr. Spinas expressed his thanks to Drs. Grüsser and Jörgens for their support and advice and to the team in Düsseldorf in general and to Mrs. Klee, Ms. Deparade and Ms. Weiss in particular for the precise handling of the accounts.

The President thanked the Honorary Treasurer for his diligence and asked if there were any questions. There were none.

c) Honorary Auditors

The President asked the Honorary Auditors, Drs. Paterson and Tack, to formally discharge the accounts. Dr. Tack confirmed that the accounts had been checked carefully and were in perfect order. Dr. Smith asked for the vote to accept the accounts.

The accounts were unanimously discharged (four abstentions).

d) Honorary Secretary

Dr. Stumvoll reported that more than 50% of those questioned in Rome scored the Meeting above average or outstanding. There had been a minor improvement in the ratings of the oral presentations.

For the Vienna Meeting, 2062 abstracts had been submitted and 1367 had been accepted. The highest number of submissions came from USA, UK and Germany. Regarding Travel Grants,146 had been awarded for the amount of €74,100.

Regarding the Stockholm Meeting, the Programme Committee had been put together and had had its first meeting. There are 16 in the Programme Committee, with one from USA. Dr. Stumvoll said he had received roughly 80 suggestions for symposia in Stockholm.

Dr. Stumvoll closed his report by thanking all members of the EASD staff, in particular Ms. H. Goliberzuch and

Mrs. M. Toledo, for their outstanding help and support with the organisation of the EASD Annual Meetings.

Dr. Smith thanked Dr. Stumvoll for his diligence and asked if there were any questions. There were none.

e) Editor-in-Chief, Diabetologia

Dr. Gale reported that the impact factor had improved, reaching the highest ever for Diabetologia, and the gap was closing on Diabetes Care. In 2008, 1694 articles had been submitted to Diabetologia; 51% went through full peer-review. The acceptance rate of 20.2% had increased slightly over 2007.

He expressed his thanks to the referees and associates and said their work was much appreciated. He also thanked his team in Bristol.

Dr. Smith thanked Dr. Gale for the excellent work he had done.

f) Chair, Postgraduate Education Sub-committee

Dr. Nolan reported that the postgraduate course in Kiev in April 2009 had been very successful and it was planned to return to the Ukraine in 2010. He thanked Dr. Boulton for the organisation of the extra-European courses in Vietnam, India and China.

Dr. Nolan reported that the web-based educational lectures were developing well and CME accreditation had been granted for these. He thanked Mr. Carey for his assistance.

Dr. Nolan thanked Dr. Czupryniak for his support as Secretary of the PGESC and the team in Düsseldorf, especially Mrs. Hata and Ms. Sommer, for their friendly assistance.

Dr. Smith thanked Dr. Nolan for his valuable work. There were no questions.

3. ELECTIONS

a) Vice President 2009-2012

The Council's election of Dr. F. Bosch was unanimously approved with one abstention.

b) Editor-in-Chief 2010-2013

The election of Dr. J. Zierath was unanimously approved with one abstention.

c) Honorary Treasurer Extension 2009-2010

The General Assembly unanimously approved Dr. Spinas' extension until 2010, with 1 abstention.

d) Chair PGESC, Extension 2009 -2010

The General Assembly unanimously approved Dr. Nolan's extension until 2010, with 1 abstention.

e) Council Members 2010-2013

The following Council Members were elected by the General Assembly:
Dr. Beguinot, F. (I) - unanimously;
Dr. Dekker, J. (NL) - 1 abstention;
Dr. Karpe, F. (UK) – unanimously;
Dr. Urbanavicius, V. (Li) - 1 abstention;

4. STUDY GROUPS

It was reported that two Study Groups had been disbanded:
Hypertension in Diabetes Study Group (HID)
Diabetes Optimization through Information Technology Study Group (DOIT)

5. HONORARY MEMBERSHIP

Drs. O. Crofford, J. Nerup and W. Waldhäusl were unanimously elected by the General Assembly.

6. ANY OTHER BUSINESS

There was no other business.

Dr. Smith thanked the out-going Vice President, Dr. C. Boitard, for his dedication and expressed his thanks for the confidence that Dr. Boitard had shown him as President.

Dr. Smith thanked the industry for their support. He also expressed his sincere gratitude to the Local Organising Committee for their outstanding contribution to the organisation of the 45th EASD Annual Meeting. He again thanked Dr. Stumvoll and the members of the Programme Committee for their hard work with regard to the scientific programme. The President warmly thanked the EASD team in Düsseldorf for their kind and efficient help.

Dr. Smith brought the General Assembly to a close at 19:00.

Agenda for the 46th General Assembly of the European Association for the Study of Diabetes

to be held in the Sutherland Hall at the Stockholmsmässan 18:00 on Thursday 23 September 2010

1. Minutes of the 45th General Assembly, Vienna, Austria 2009

2. Reports

a) President	Dr. U. Smith
b) Honorary Treasurer	Dr. G. Spinas
c) Honorary Auditors	Dr. K. Paterson Dr. C. Tack
d) Honorary Secretary	Dr. M. Stumvoll
e) Editor-in-Chief, Diabetologia	Dr. E. Gale
f) Chair, Postgraduate Education Subcommittee	Dr. J. Nolan
g) Chair, Extra-European Postgraduate Activities	Dr. A. J. M. Boulton

3. Elections

a) Extension, Honorary Treasurer (2010 - 2011)	G. Spinas
b) Honorary Secretary (2010 – 2013)	in place of M. Stumvoll
c) Chair, PGESC (2010 – 2013)	in place of J. Nolan
d) Council Members (2011 - 2014)	in place of T. BattelD. Matthews J. Philippe J. Zierath
e) Honorary Auditor (2010 - 2013)	in place of C. Tack

4. Study Groups

5. Honorary Membership

6. Any other business

46th EASD Annual Meeting of the European Association for the Study of Diabetes

Stockholm, Sweden, 20 – 24 September 2010

Abstracts

Index of Oral Presentations

Index of Poster Sessions

PS 29 Glucose and mitochondrial metabolism

OP 1 Novel formulations and delivery of insulin

1

Gene therapy for diabetic hyperglycaemia by expressing insulin and glucokinase in skeletal muscle: pre-clinical studies in diabetic dogs

D. Callejas[1,2], C.J. Mann[1], J. Montane[1], E. Ayuso[1,2], X. Leon[1,2], A. Andaluz[3], F. Mingozzi[4], K.A. High[4], F. Bosch[1,2];
[1]CBATEG and Department of Biochemistry and Molecular Biology, School of Veterinary Medicine, Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]CIBER of Diabetes and Associated Metabolic Disorders, Barcelona, Spain, [3]Department of Medicine and Animal Surgery, School of Veterinary Medicine, Universitat Autonoma de Barcelona, Bellaterra, Spain, [4]Children's Hospital of Philadelphia, Abramson Research Center, Philadelphia, USA.

Background and aims: We previously demonstrated the feasibility of a potential gene therapy strategy for type 1 diabetes based upon engineering mouse skeletal muscle to co-express human insulin (hIns) and glucokinase (Gck). Both genes act synergistically such that local production of hIns improves glucose uptake, whereas Gck acts as a glucose sensor in a concentration-dependent manner to facilitate glucose disposal. We wished to perform a pre-clinical study in diabetic dogs to demonstrate the feasibility, efficiency, duration of effects as well as any biochemical and safety issues.
Materials and methods: Five dogs were made diabetic with streptozotocin and alloxan. Dog 1 was treated subsequently after diabetes induction with 2.5E12 vg/kg of AAV1-CMV-hIns. Dog 2 was given AAV1-CMV-hIns (1.0E12 vg/kg) only, whereas dogs 3 and 4 received AAV1-CMV-hIns and AAV1-CMV-Gck simultaneously (1.0E12 vg/kg each vector). In addition, Dog 5 was left as an untreated diabetic control for 8 months before receiving the same treatment as Dog 3.
Results: In Dog 1 human C-peptide was successfully detected in serum and associated with improved glucose disposal after oral glucose tolerance test (GTT) and a reduced fasting glycaemia in the absence of any negative response to the vector. Dog 1 was sacrificed at 3 weeks after the treatment and insulin expression was confirmed by qPCR and Northern Blot in skeletal muscle, but not in other tissues. In the other four additional dogs that were treated with lower doses we wanted to find the minimum effective dose of AAV1-CMV-hIns able to produce normoglycaemia in fasting conditions. Circulating levels of human C-peptide were detected for >3 years after injection in Dogs 2, 3 and 4 and for >2 years in Dog 4. Dog 2 showed a nearly normalized fasting glycaemia whereas Dog 3, 4 and 5 achieved completely normalized fasting glycaemia and a vastly improved ability to dispose of glucose compared to Dog 2 or Dog 4 when diabetic, by GTT, suggesting the concerted action of hINS and Gck. Dog 5 demonstrated a continuous deterioration in weight and biochemical parameters (AST and ALT) while diabetic which was immediately rectified upon treatment.
Conclusion: Taken together, these results suggest that engineering skeletal muscle to produce insulin and glucokinase may be a potential therapy for the treatment of type 1 diabetes, because it shows long term efficacy and safety.

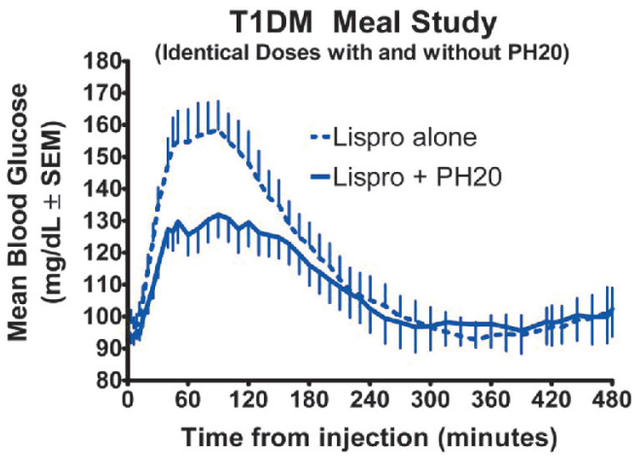
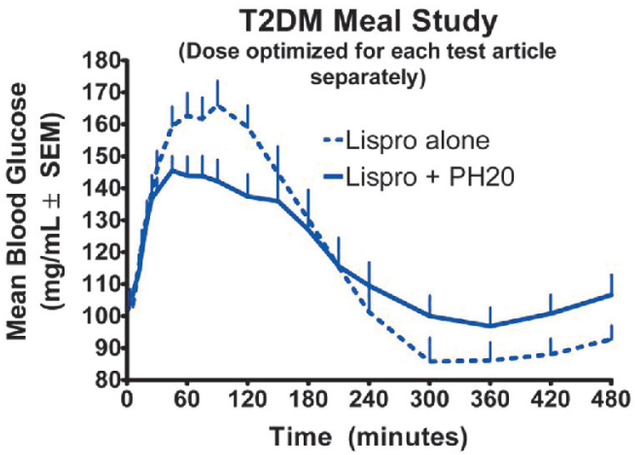
2

Improved glycaemic variability in type 1 diabetes mellitus and type 2 diabetes mellitus patients by coinjection of prandial insulin analogue with human hyaluronidase

M. Hompesch[1], D. Muchmore[2], L. Morrow[1], E. Ludington[2], D. Vaughn[2];
[1]Profil Institute for Clinical Research, Chula Vista, [2]Halozyme Therapeutics, Inc., San Diego, USA.

Background and aims: Studies in T1DM and T2DM patients to compare the postprandial glucose (PPG) response to a liquid meal for insulin lispro injected ± human hyaluronidase (PH20).
Materials and methods: Two standardized liquid meal studies were conducted; one in 22 T1DM patients [15 male, 9 female; mean age 40.7 (±10.7); mean BMI 24.2 (± 2.9)] and the other in 23 T2DM patients [14 male, 9 female; mean age 52 (37-69); mean BMI 33.5 kg/m2 (23.7-45.0)] on high insulin doses, mean daily dose 105U (60-230). Patients fasted (10h) and refrained from SC insulin (>9h) before dosing. 2h before a liquid meal (60g CHO for T1DM or 80g CHO for T2DM), patients were titrated to 110±20mg/dL glucose target with IV glucose and/or IV insulin followed by a 30min intervention-free period. For the T1DM study, an optimum dose was found for lispro+PH20 during up to 3 dose-finding visits (targeting a postprandial range of 60-160 mg/dL) and the same dose was studied for lispro alone, while for the T2DM study the optimum dose (targeting a postprandial range of 70-140mg/dL) was separately optimized for lispro±PH20 (from 3 dose-escalating test meal visits each). Lispro±PH20 was injected SC immediately pre-meal, and plasma insulin and glucose concentrations were monitored for 8h.
Results: PH20 coinjection reduced hyperglycemic excursions in both studies with the same (T1DM) or reduced (T2DM) hypoglycemic risk. In the T1DM study, peak PPG was reduced from 174 to 148 mg/dL (p=.002) and the total hyperglycemic excursions (AUC > 140 mg/dL) were reduced 79%, allowing more patients to reach PPG goal (91% +PH20 v. 55% for lispro alone met the ADA goal of ≤180mg/dL). In the T2DM study, peak PPG was reduced from 178 to 165 mg/dL (p=.095) and the total hyperglycemic excursions (AUC > 140 mg/dL) were reduced 44%, allowing more patients to reach PPG goal (71% +PH20 v. 48% for lispro alone met the ADA goal of ≤180mg/dL). Hypoglycemic risk was similar in the T1DM study with equal lispro doses, and reduced in the T2DM study where the optimum dose was reduced by 8% for lispro+PH20. All injections were well tolerated.
Conclusion: Lispro+PH20 provided superior control of postprandial blood glucose compared to lispro alone in patients with both T1DM and T2DM in these test meal settings.





3

30 month post trial follow up of HbA_{1c} with continuous intraperitoneal insulin infusion in type 1 diabetes

S.J.J. Logtenberg[1], N. Kleefstra[1,2], S.T. Houweling[2], K.H. Groenier[3], H.J.G. Bilo[1,4];
[1]Diabetes Centre, Isala Clinics, Zwolle, [2]Langerhans Medical Research Group, Zwolle, [3]General Practice, UMCG, Groningen, [4]Internal medicine, UMCG, Groningen, Netherlands.

Background and aims: Results from our randomized controlled trial (RCT) showed that with continuous intraperitoneal (IP) insulin infusion with an implantable pump (see Figure 1) it is possible to achieve better glycemic control and quality of life compared to subcutaneous insulin administration in patients with type 1 diabetes (T1DM). The aim of this analysis was to investigate patients therapy choice and glycemic control 30 months after the end of the trial.
Materials and methods: The 23 patients that ended the RCT in 2007/2008 all continued to use the IP pump. Last known HbA1c values were collected in the first quarter of 2010. Status regarding therapy mode were extracted from hospital records. Paired t-tests were used to compare HbA1c at the end of the IP study phase with mean HbA1c at follow up.
Results: In March 2010, 22 (12 female, 10 male) patients were still treated with CIPII, 1 patient (female) was back on subcutaneous insulin due to neuropathic pains, for which the patient blamed the IP pump. Mean age at follow up was 46.6 (12.0) years; mean diabetes duration at the start of the study was 22.6 (10.6) years; mean baseline HbA_{1c} 8.6 (1.1) %; HbA_{1c}>7.5% in 20 subjects; hypoglycemic events ≥5/week in 14 subjects. HbA1c was collected after 2.3 (0.6) years after the end of the study. Mean HbA1c was 7.7% (1.1). Compared to prestudy HbA1c values, this is a significant reduction of 0.83% (CI; -1.3, -0.4). Compared to the end of the IP phase of the trial, the results are comparable (0.2% (CI; -0.3, 0.7).
Conclusion: Our analysis shows that with CIPII it is possible not only to improve glycemic control in the short term, but also to achieve sustained improvement in glycemic control in patients with T1DM who were insufficiently controlled previously despite intensified subcutaneous insulin regimens. Furthermore, there is a low drop out rate with CIPII (1 out of 23 of patients).

Insulin degludec, a new generation ultra-long acting insulin, used once daily or 3-times weekly in people with type 2 diabetes: comparison to insulin glargine

C. Mathieu[1], G. Fulcher[2], P.V. Rao[3], N. Thomas[4], L. Endahl[5], T. Johansen[5], A.J. Lewin[6], J. Rosenstock[7], M. Pinget[8], B. Zinman[9];
[1]UZ Gasthuisberg K.U.Leuven, Belgium, [2]Royal North Shore Hospital, University of Sydney, Australia, [3]Nizam's Institute of Medical Sciences University, Hyderabad, India, [4]Christian Medical College, Vellore, India, [5]Novo Nordisk A/S, Soeborg, Denmark, [6]National Research Institute, Los Angeles, [7]Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA, [8]University Hospital Strasbourg, France, [9]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, University of Toronto, Canada.

Background and aims: Insulin degludec (IDeg) is a novel insulin analog that forms soluble multi-hexamer assemblies after s. c. injection, resulting in ultra-long duration of action. The aim of this phase 2 trial was to investigate the efficacy and safety of IDeg formulations administered once daily (OD) or 3-times weekly (3TW) in insulin-naïve people with type 2 diabetes inadequately controlled on OADs.
Materials and methods: This was a 16-week, open-label, randomized, 4-arm, parallel-group, treat-to-target trial. Participants (mean: 54.2 years, HbA_{1c} 8.7%, fasting plasma glucose (FPG) 10.2 mmol/l, BMI 29.5 kg/m^2) received an OD formulation of IDeg (IDeg OD, n=60), a 3TW formulation of IDeg (IDeg 3TW, n=62), an alternative IDeg OD formulation (development discontinued, results not shown, n=61) or insulin glargine OD (IGlar, n=62), all in combination with metformin. All insulins were injected s. c. in the evening and titrated to achieve FPG 4.0-6.0 mmol/l. www.clinicaltrials.gov ID: NCT00611884.
Results: HbA_{1c} after 16 weeks of treatment was similar across treatment arms with regard to mean reduction from baseline (IDeg OD: -1.3%; IDeg 3TW: -1.5%; IGlar: -1.5%; p=NS for all pairwise comparisons) and final mean value (IDeg OD: 7.4%; IDeg 3TW: 7.3%; IGlar: 7.2%). Treatments were also comparable with respect to final mean FPG (IDeg OD: 6.3 mmol/l; IDeg 3TW: 6.5 mmol/l; IGlar: 6.4 mmol/l) and mean reductions from baseline (IDeg OD: -3.6 mmol/l; IDeg 3TW: -4.2 mmol/l; IGlar: -3.4 mmol/l). At end-of-trial, mean weekly insulin dose was similar for IDeg OD (3.1 U/kg/week=0.45 U/kg/day), IDeg 3TW (3.4 U/kg/week=0.49 U/kg/day) and IGlar (3.3 U/kg/week=0.48 U/kg/day). Body weight remained stable throughout the trial in all treatment arms. Rates of confirmed hypoglycemia (PG <3.1 mmol/l or requiring assistance) were low and only one severe event was reported (for IDeg 3TW). The rate of confirmed hypoglycemia appeared lower for IDeg OD than IDeg 3TW and IGlar (0.6, 2.3, 1.1 events/patient year, respectively; p=NS for both comparisons). The proportion of subjects with adverse events (AEs) was similar across treatment arms (IDeg OD: 47%; IDeg 3TW: 50%; IGlar: 66%) with no specific patterns or clustering. The majority of AEs were mild or moderate in severity.
Conclusion: This proof-of-concept trial demonstrated that IDeg used 3-times weekly or once daily was safe, well tolerated and provided similar glycemic control to IGlar.

Glycosylated hemoglobin and hypoglycaemia in patients with type 2 diabetes mellitus: Technosphere insulin and usual antihyperglycaemic regimen vs usual antihyperglycaemic regimen

A.H. Boss[1], P. Raskin[2], M. Phillips[1], A. Rossiter[1], P.C. Richardson[1];
[1]MannKind Corporation, Valencia, [2]University of Texas Southwestern Medical Center at Dallas, USA.

Background and aims: Technosphere Insulin (TI) is an ultra-rapid-acting inhaled insulin with a pharmacokinetic profile well suited for earlier control of postprandial plasma glucose. One objective of this trial was to compare the efficacy and safety of prandial TI with usual diabetes care (UC) in patients with type 2 diabetes mellitus (T2DM) with inadequate glycemic control (glocosylated hemoglobin [A1C] >6.6%, ≤12.0%).
Materials and methods: Patients either incorporated TI into their usual antihyperglycemic regimen (TI group; n=656), or continued their usual antihyperglycemic regimen, which could include insulin, oral hypoglycemic drugs, and/or diet and exercise (UC group; n=678) over 2 years.
Results: Mean baseline characteristics were similar between groups. The average TI daily dose was 141.7±62.9 U. At 2 years, there was comparable reduction between groups in A1C (0.70% [TI], 0.59% [UC], p=0.30; see Figure). Total hypoglycemic event rates were 0.15 per patient-month in the TI group compared with 0.24 per patient-month for UC patients on insulin (p=0.03); mild/moderate (M/M), 0.15 per patient-month in the TI group compared with 0.24 per patient-month for UC patients on insulin (p=0.04); and severe, 0.53 per 100 patient-months in the TI group compared with 1.17 per 100 patient-months for UC patients on insulin (p=0.08). Weight gain in the TI group was +1.56 kg compared with 1.75 kg in the UC group (p=0.67).
Conclusion: In patients with T2DM, antihyperglycemic regimens containing prandial TI resulted in comparable A1C reductions, significant reductions in overall and M/M events, and a numerical reduction in severe hypoglycemic event rates.

A novel pH-neutral formulation of the monomeric insulin VIAject® has a faster onset of action than insulin lispro

L. Nosek[1], T. Heise[1], F. Flacke[2], A. Krasner[2], P. Pichotta[2], L. Heinemann[1], S.S. Steiner[2];
[1]Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, [2]Biodel Inc, Danbury, USA.

Background and aims: VIAject® is a monomeric insulin with a very fast onset of action. Previous studies used a formulation of VIAject with a concentration of 25 U/ml and a pH of about 4 (VJ25). In this double-blind, cross-over glucose clamp study we compared the pharmacodynamic (PD) and pharmacokinetic (PK) properties of a novel formulation of VIAject with a concentration of 100 U/ml and a neutral pH (VJ7) with those of VJ25 and insulin lispro (LIS).
Materials and methods: Fourty-three people with type 1 diabetes (21 female, age 43 (21-65) years, BMI 24.1 (20-28) kg/m^2, HbA1c 7.5 (5.7-9.5)%) received 12 U of either insulin under euglycemic glucose clamp conditions (Biostator-clamp, duration 8h postdose).
Results: VJ7 was bioequivalent to VJ25 (90% confidence interval of the ratios for total insulin (INS) AUCs and INS_{max} within 0.80-1.25). Compared with LIS, VJ7 showed a significantly faster absorption (t- INS_{max} 23 vs. 60 min, difference -30 [90% Confidence Interval (CI) -35;-23] min; t-$INS_{50\%early}$ 8 vs. 22 min, difference -16 [CI -17;-14] min; p<0.05 respectively) and faster onset of action (time to early half-maximal glucose infusion rate (GIR) 25 vs. 44, difference -18 [CI -26;-10] min, p<0.05), a higher GIR-AUC in the first 60 min post-dose (176 vs 107, ratio 1.65 [CI 1.27;2.14] mg/kg, p<0.05) and a slightly higher value for AUC-GIR_{total} (1263 vs. 1095, ratio 1.15 [CI 1.06;1.26] mg/kg; p<0.05). GIR_{max} was similar between VJ7 and LIS (6.1 vs. 6.6, ratio 0.93 [CI 0.86;1.01] mg/kg/min) as was t-$INS_{50\%late}$ (136 vs. 129, difference 7 [CI -15;27] min) whereas the duration of action was longer with VJ7 (t-$GIR_{50\%late}$ 274 vs. 228, difference 50 [CI 25;73] min; p<0.05).
Conclusion: The novel, pH-neutral formulation of VIAject is bioequivalent to the previously used formulation and has a significantly faster absorption and onset of action than insulin lispro.

OP 2 Screening and prevention of gestational diabetes

7

Hyperglycaemia and Adverse Pregnancy Outcome (HAPO) Study: Frequency of gestational diabetes mellitus (GDM) at collaborating centers based on IADPSG consensus panel recommended criteria

D.R. Hadden[1], B.E. Metzger[2], L.P. Lowe[3], A.R. Dyer[3], D.R. Coustan[4], M. Hod[5], J.J.N. Oats[6], B. Persson[7], E.R. Trimble[8], HAPO Study Cooperative Research Group;
[1]Endocrinology, Royal Victoria Hospital, Belfast, United Kingdom, [2]Medicine, Northwestern University, Chicago, [3]Preventive Medicine, Northwestern University, Chicago, [4]Obstetrics & Gynecology, Women and Infants Hospital, Providence, USA, [5]Obstetrics & Gynecology, Helen Schneider Hospital for Women, Rabin Medical Center, Tel Aviv, Israel, [6]Obstetrics & Gynecology, Royal Women's Hospital, Melbourne, Australia, [7]Pediatrics, Karolinska Institute, Stockholm, Sweden, [8]Endocrinology, Queen's University Belfast, United Kingdom.

Background and aims: New criteria for GDM were recommended by the International Association of Diabetes in Pregnancy Study Groups (IADPSG). The aim is to apply the criteria to determine frequency of GDM at HAPO Study field centers.
Materials and methods: The IADPSG thresholds are one or more OGTT plasma glucose values => 5.1, 10.0, 8.5 mmol/l for fasting, 1-hr and 2-hr glucose respectively. These were applied to the blinded participants at the 15 field centers that collaborated in the HAPO Study.
Results: GDM was diagnosed in 16.1% of the blinded study population. An additional 1.7% was unblinded with an OGTT glucose value above pre-defined levels bringing the overall figure to 17.8%. However, there was considerable center-to-center variation of the study participants in maternal age, body mass index, frequencies of family history of diabetes and hypertension. Adjusting for these variables and for field center reduced, but did not eliminate center-center differences which in all likelihood reflect racial/ethnic group differences in the potential risk of disorders of glucose metabolism in these populations.
Conclusion: Using the diagnostic thresholds recommended by the IADPSG Consensus Panel, the frequencies of GDM show substantial variability between and within regions of the world. These variations may influence the future development of optimal, cost- effective strategies for detection and treatment of GDM.

Unadjusted Frequency of GDM at HAPO Field Centers

Field Center	Frequency (%)	Field Center	Frequency (%)
Bellflower, USA	22.9	Petah Tiqva, Israel	9.2
Chicago, USA	16.5	Beersheba, Israel	8.7
Providence, USA	14.2	Bangkok, Thailand	21.2
Cleveland, USA	23.7	Brisbane, Australia	12.1
Toronto, Canada	14.6	Newcastle, Australia	13.6
Belfast, UK	15.5	Singapore, Singapore	22.4
Manchester, UK	21.0	Hong Kong, China	**13.4**
Barbados, West Indies	9.9	HAPO Overall	16.1

Analysis of pregnancies after new IADPSG recommendation

A. Lapolla[1], M. Dalfrà[1], E. Ragazzi[2], A. De Cata[1], M. Masin[1], B. Bonsembiante[1], D. Fedele[1];
[1]Medical and Surgical Sciences, [2]Pharmacology and Anaesthesiology, University of Padova, Italy.

Background and aims: The IADPSG Consensus Panel recently has suggested new diagnostic criteria for gestational diabetes (GDM) diagnosis. Aim of our study was to evaluate clinical and metabolic characteristics and pregnancy outcome in women prior classified normal by Carpenter and Coustan criteria and now GDM according to the new recommendations.

Materials and methods: We retrospectively analyzed 3953 pregnancies: 2138 GDM and 1815 NGT by the new criteria: in the GDM group 112 women (2.8%) (GDM-NGT) were NGT with the old classification. We evaluated this group compared with GDM and NGT ones.
Results: As for clinical and metabolic parameter GDM-NGT women were younger (32.4 ± 4.5 yrs vs 33.4 ± 4.4 yrs, p=0.0039) and had a lower pre-pregnancy BMI (23.7 ± 4.3 kg/m^2 vs 24.7 ± 5.1 kg/m^2, p=0.005) than GDM ones, while gestational week at diagnosis and HbA1c levels at diagnosis and at the 3rd trimester were not different. The analysis of OGTT showed that ,at all point of curve, glucose levels were significant higher in GDM-NGT with respect to NGT ones (basal 90.5 ± 7.8 mg/dl vs 79.2 ± 6.8 mg/dl, p<0.0001; 60': 153.7 ± 18.8 vs 140.6 ± 23.7, p<0.0001, 120': 129.3 ± 20.6 vs 116.3 ± 20, p<0.0001). As for pregnancy outcome, caesarean section was 43.6% in GDM-NGT group, 41% in GDM (n.s.) and 31.1% in NGT (p=0.008); gestational age at delivery and birthweight were not different. Ponderal index (g/cm^3)was significant higher in GDM-NGT with respect to GDM and NGT (2.95 ± 0.61 vs 2.8 ± 0.41 and vs 2.77 ± 0.34, p<0.0001 respectively). A correlation analysis showed that pre-pregnancy BMI and basal glucose level were significant related with newborn ponderal index (p<0.0001, p<0.05 respectively).
Conclusion: So the new GDM diagnostic criteria recommended by IADPSG identified a new group of GDM women that, classified normal with Carpenter and Coustan criteria, show metabolic characteristics and pregnancy outcome similar to those of GDM women.

New criteria for the diagnosis of gestational diabetes mellitus in comparison to former diagnostic criteria concerning maternal postpartum glucose levels and neonatal complications

T. Prikoszovich[1], D. Bancher-Todesca[2], R. Weitgasser[3], H. Steiner[4], G. Schernthaner[5], B. Schneider[6], C. Marth[7], M. Lechleitner[8], A. Kautzky-Willer[9];
[1]Department of Internal Medicine III, Division of Nephrology and Dialysis, Medical University of Vienna, [2]Obstetrics and Gynecology, Medical University of Vienna, [3]First Department of Medicine, Paracelsus Private Medical University Salzburg, [4]Obstetrics and Gynecology, Paracelsus Private Medical University Salzburg, [5]Department of Internal Medicine I, Rudolfstiftung Vienna, [6]Department of Medical Statistics, Medical University of Vienna, [7]Obstetrics and Gynecology, Medical University of Innsbruck, [8]Department of Internal Medicine, Medical University of Innsbruck, [9]Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria.

Background and aims: New criteria for the diagnosis of gestational diabetes (GDM) were recently proposed by the Consensus Panel of the International Association of Diabetes Pregnancy Study Groups (ICP). We aimed to examine whether these new criteria (GDM-ICP) select women and children at risk better than criteria of the Forth International Workshop Conference of GDM (GDM-WC4) using the 2-hour 75g oral glucose tolerance test (OGTT).
Materials and methods: This was a prospective longitudinal open study in five tertiary care centers in Austria. 1466 women underwent an 2-hour 75g-OGTT between the 24th and 28th gestational week and were treated if at least one value according to the GDM-WC4 was met or exceeded (GDM-WC4/1) in keeping with the recommendations of the Austrian and German Diabetes Association at that time. We evaluated the impact of risk factors, different thresholds (GDM-ICP vs. GDM-WC4/1) on fetal/neonatal complications and maternal postpartum glucose tolerance in pregnant women.
Results: Forty-nine percent of all women were diagnosed according to GDM-ICP, whereas forty-six percent according to GDM-WC4/1. GDM-ICP identified a higher rate of obstetrical complications. We found 6.1 % more large for gestational age neonates (p=0.0047), 3.26% more cesarean sections (p=0.0001) and 4.5% more neonates with birth weight >4000g (p=0.0047) than with the former criteria. The rate of women with risk factors (history of GDM or prediabetes, intrauterine fetal death, birth weight over 4000g, malformation, previous recurrent abortus, ethnic group at risk, adiposity, hypertension, dyslipidemia, preterm delivery, age, family history for DM2, glucosuria and macrosomia) detected by the GDM-ICP was increased by 2.6% (p<0.0001). However concerning impaired postpartum glucose tolerance we found no differences.
Conclusion: These results support the use of the new, more stringent criteria proposed by ICP for the diagnosis of GDM (GDM-ICP), because they can detect more obstetrical complications than the former diagnostic criteria (GDM-WC4/1) in a Central European population.

ATLANTIC DIP: Prevalence and implications of abnormal glucose tolerance in pregnancy in Ireland

E.P. O'Sullivan[1], G. Avalos[2], M.W. O'Reilly[1], C. Dennedy[1], F. Dunne[1];
[1]Diabetes, Galway University Hospital, [2]Medicine, National University of Ireland Galway, Ireland.

Background and aims: While many authorities now recommend universal screening for gestational diabetes mellitus (GDM), this is not available in the Irish Health Service. Consequently, the true prevalence of abnormal glucose tolerance (and its implications) in pregnancy is unknown.
Materials and methods: ATLANTIC DIP (Diabetes In Pregnancy) is a multicentre study on the west coast of Ireland which offers universal screening for gestational diabetes mellitus (GDM) using a 75g oral glucose tolerance test at 24-28 weeks. Normal glucose tolerance (NGT), impaired glucose tolerance (IGT) and GDM were defined according to standard WHO criteria. Maternal and foetal outcomes were recorded. Statistical analysis was performed using SPSS, and all results were adjusted for maternal age and body mass index (BMI).
Results: Between 2006 and 2008, 5,670 women (mean age 1.5±5.4yrs, mean BMI 26.9±5.1kg/m^2, 93.4% Caucasian) were screened. 5,100 (89.9%) women had a NGT, 431 (7.6%) had IGT, and 139 (2.5%) had GDM. The table below shows the Odds ratios [95% confidence intervals] of adverse maternal and foetal outcomes for IGT and GDM compared to NGT.
Conclusion: One in ten women screened had IGT or GDM. Given this prevalence and the associated significant adverse maternal and foetal outcomes, consideration should be given to universal screening for GDM throughout Ireland.

Adverse maternal and foetal outcomes

	IGT	GDM	IGT/GDM
Hypertensive disorder of pregnancy	1.4[0.9-2.1]	1.9[1.0-3.6]	1.5[1.0-2.2]

Is maternal educational level a risk factor for gestational diabetes in caucasian women?

A. Bertolotto[1], M. Corfini[1], A. Ghio[1], V. Resi[1], C. Lencioni[1], L. Battini[2], L. Volpe[1], G. Di Cianni[1];
[1]Department of Endocrinology and Metabolism, Section of Diabetes and Metabolic Diseases, University Hospital, [2]Department Maternal-Childish, University Hospital, Pisa, Italy.

Background and aims: Gestational Diabetes (GDM) is associated with features of Metabolic Syndrome (MS) and Cardiovascular Disease (CVD); low socio-economic status is a well known risk factor for these conditions. So, we performed this study to evaluate if maternal educational level (MEL) may be associated with the development of GDM as well as impaired glucose tolerance (IGT).
Materials and methods: From 2006 to 2009 we examined a cohort of Caucasian pregnant women attending 3-h 100-g OGTT in our Department of Diabetes. According to ADA criteria, GDM and IGT were diagnosed when almost 2 or 1 plasma glucose concentrations exceeded the cut-off levels, respectively. At the enrolment, upon collection of anthropometric and clinical parameters, we assessed the MEL on the basis of the level of attended school, evaluated by a questionnaire. So the women were categorized into three levels: low (primary school; L), intermediate (high school; I) and high (university; H) level.

Results: We studied 1012 Caucasian pregnant women (mean age 33.8±4.4 yrs;) at 27.4±4 wks of gestation: 20% L, 48.6% I and 31.4% H. L women were younger (33.4±6.2 vs 33.2 ± 4.3 and 34.9±3.7 yrs, p<0.0002) heavier (BMI 25.7±5.6 *vs* 24.2±5 and 23±3.9 kg/m^2, p<0.0001) with an higher rate of obesity (22.4% *vs* 12% and 6.9%, p<0.0001) and an higher weight gain during pregnancy(10.9±4.9 *vs* 10.4±5.8 and 9.7±3.6 kg, p<0.01) while H women were older than others (L 33.4±6.1 and I 33.2±4.3 *vs* H 34.9±3.7; p< 0.002). No differences were observed in family history for type 2 diabetes (27% L, 26% I and 21.5% H) and parity (primiparous: 45% L, 44% I and 40% H). IGT and/or GDM was diagnosed in 58(29%) L, 124(25%) I and 80(25 %) H women, without difference among the three groups. IGT and GDM diagnosis were not related to MEL, while after multivariate logistic regression analysis including all clinical and metabolic parameters, only prepregnancy BMI (F test value 12.148 p< 0.005) and age (F test value 9.318 p< 0.001) were independently associated with IGT or GDM diagnosis.
Conclusion: We failed to find any relationship between abnormal OGTT and maternal education levels. Probably in our population, differently than others, low education level is not a condition of deprivation and low health knowledge. Prepregnancy BMI and old age remain the best predictors of abnormal glucose tolerance during pregnancy. Obese and older women, independently of their education levels, have to be addressed to programs for preventing the development of glucose abnormalities during pregnancy.

Metformin does not prevent gestational diabetes mellitus in women with polycystic ovarian syndrome
S.M. Carlsen[1], E. Vanky[2];
[1]Department of Cancer Research and Molecular Medicine, [2]Department of Laboratory Medicine, Children`s and Women`s Health, Norwegian University of Science and Technology, Trondheim, Norway.

Background: It is held that gestational diabetes mellitus (GDM) increases pregnancy complications and adverse pregnancy outcome. Metformin is also suggested to prevent pregnancy complications in women with polycystic ovary syndrome (PCOS). And some propose that metformin should be used to treat GDM.
Material and methods: In the first trimester of pregnancy, 273 PCOS women were randomized to metformin or placebo. At inclusion, gestational week 19 and 32, an OGTT were performed and pregnancy complications were recorded.
Results: At inclusion, 13 women in the placebo group and 10 in the metformin group had GDM. During the rest of the pregnancy 21/125 (16.9%) in the placebo group and 22/125 (17.6%) in the metformin group developed GDM (p=0.87). Insulin was required in four patients in the placebo group and none in the metformin group. We found no differences in mean birth weight (3524 ± 559 vs 3543 ± 601, p=0.82), in the incidence of preterm delivery (2/64 (3.1%) vs. 14/206 (6.8%), p=0.83) and preeclampsia (3/64 (4.7%) vs. 12/206 (5.8%), p= 0.69) between those who developed GDM and those who did not.
Conclusion: Our findings do not support the view that metformin prevents GDM in women with PCOS. This is rather surprising, given the effect of metformin in non-pregnant patients with diabetes mellitus type 2. In pregnant women insulin resistance increases. However, the pathogenetic mechanisms involved in the development of GDM may be different from the mechanism responsible for increased insulin resistance in non-pregnant women. Metformin may lack effect on the mechanism responsible in increasing gestational insulin resistance. The incidence of preterm delivery and preeclampsia were equal in PCOS women with and without GDM. This observation contradicts the view that GDM or blood glucose levels per se are directly involved in the development of preeclampsia and preterm delivery. If our observations are confirmed by future studies, other endocrine or metabolic aberrations associated with decreased glucose sensitivity must be responsible for the increased incidence of preeclampsia and preterm delivery seen in women with GDM. The observation that birth weight was not increased in offspring of PCOS women with GDM compared to those with normal glucose homeostasis is surprising. Our observations indicate that future studies on GDM should differentiate between PCOS women and non-PCOS women. In conclusion the present study does not support that metformin prevents the development of GDM in PCOS pregnancies. GDM in PCOS women is not associated with increased pregnancy complications or increased birth weight.

OP 3 Cardiovascular disease in type 1 diabetes

13

Higher plasma advanced glycation endproducts levels are associated with incident cardiovascular disease and all-cause mortality in type 1 diabetes: a 12-year follow-up study
J.W.M. Nin[1], A. Jorsal[2], I. Ferreira[1], C.G. Schalkwijk[1], M.H. Prins[3], H.-H. Parving[4], L. Tarnow[2], P. Rossing[2], C.D.A. Stehouwer[1];
[1]Internal Medicine, Maastricht University Medical Centre, Netherlands, [2]Steno Diabetes Center, Gentofte, Denmark, [3]Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, Netherlands, [4]Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark.

Background and aims: Advanced glycation endproducts (AGEs) may constitute a pathophysiologic mechanism linking hyperglycaemia to the development of vascular complications. Therefore, we investigated the associations of plasma levels of AGEs with incident cardiovascular disease (CVD) and all-cause mortality in individuals with type 1 diabetes, and the extent to which any such associations could be explained by endothelial and renal dysfunction, low-grade inflammation and arterial stiffness.
Materials and methods: We prospectively followed 169 individuals with diabetic nephropathy and 170 individuals with persistent normoalbuminuria (205 men, mean age at baseline of 41±10 yrs) who were free of CVD at study entry and in whom levels of AGEs (expressed as the average of the z-scores of N$^{\varepsilon}$-(carboxymethyl)lysine, N$^{\varepsilon}$-(carboxyethyl)lysine and pentosidine) and other biomarkers were measured at baseline. The median follow-up duration was 12.3 (inter-quartile range: 7.6-12.5) years. Data were analysed with Cox regression analyses.
Results: During the course of follow-up, 82 individuals (24.2%) died; 85 (25.1%) suffered a fatal (n=48) and/or non-fatal (n=53) CVD event. The incidence of cardiovascular morbidity and mortality (Fig. 1A) and of all-cause mortality (Fig. 1B) increased with higher baseline levels of AGEs independently of traditional CVD risk factors (as detailed in footnote to figure): hazard ratio (HR)=1.30 (95%CI=1.02 to 1.65) and HR=1.29 (1.01 to 1.65) per 1 SD increase in AGEs score, respectively. Adjustment for estimated glomerular filtration rate (eGFR), but not for markers of endothelial dysfunction, low-grade inflammation and arterial stiffness, attenuated these associations to HR=1.16 (0.89 to 1.51) and HR=1.19 (0.90 to 1.57), respectively. Higher levels of AGEs were inversely associated with baseline eGFR: standardised regression coefficient=-0.29 (-0.38 to -0.20).
Conclusion: Higher levels of AGEs are associated with incident cardiovascular morbidity and mortality as well as all-cause mortality in individuals with type 1 diabetes. AGEs-associated renal dysfunction may partially explain these associations.

Repeated episodes of hypoglycaemia aggravate preclinical atherosclerosis in a group of young adult subjects with type 1 diabetes

M. Giménez[1,2], R. Gilabert[3], J. Monteagudo[4], A. Alonso[1], R. Casamitjana[5], C. Paré[6], I. Conget[1,2];
[1]Endocrinology and Diabetes Unit, [2]CIBERDEM, [3]Radiology Unit, [4]Haemostasia Unit, [5]Hormonal Unit, [6]Echocardiology Unit, Hospital Clínic, Barcelona, Spain.

Background and aims: Type 1 Diabetes (T1D) is associated with an increased age-adjusted relative risk for atherosclerosis even though many of the classical cardiovascular risk factors (CVRF) are absent. While intensive insulin therapy reduces the risk of complications, it is associated with an increase in hypoglycaemia. Hypoglycaemia acutely provokes intense changes in haemodinamics and several haemorreological parameters. However, its role when chronically repeated as an accelerating factor for CV disease in diabetes is still far from proven.
Aims: To evaluate whether repeated episodes of hypoglycaemia represent an aggravating factor for vascular disease in subjects with T1D.
Materials and methods: Twenty-five T1D patients (34.6±7.8 years, 14 women, T1D duration 16.1±6.3 years, HbA_{1c} 6.6±1.0) with >4 non-severe-hypoglycaemia (NSH)/week and ≥2 severe hypoglycaemia (SH)/previous year and without additional CVRF, micro/macrovascular complications (including normal stress echocardiography) and no autonomic dysfunction were included (H-Group). In addition, 20 T1D subjects were selected as an age-sex matched control group presenting <2 NSH/week, no previous SH and without micro/macro/autonomic complications (C-Group). Previous to the CV evaluation, an acute induction of hypoglycaemia was performed to assess hypoglycaemia awareness. Inflammation/endothelial markers including leukocytes, Von Willebrand factor (VW), fibrinogen and ICAM-1 were also measured. B-mode-ultrasound was used to evaluate flow-mediated-dilatation in braquial artery (FMD) and intima-media-thickness (IMT) at both carotid/femoral sites. A 72-h blinded CGMS was recorded.
Results: As expected, H-Group subjects had significantly higher number of NSH/week and SH than C-Group (NSH/week 5.2±1.9 vs. 0.3±0.5 p<0.01). In addition, they displayed hypoglycaemia unawareness by Clarke's test and by symptomatic response to hypoglycaemia (Edinburgh's scale). Unsurprisingly, higher percentage of values and AUC <70mg/dl were observed in H-Group (14.2±8.9 vs. 6.3±7.1%, p<0.02 and 2.4±1.8 vs. 0.6±1.0 AUC, p<0.01). The percentage of maximal FMD was lower in H-Group than in C-Group (6.52±2.92 vs. 8.62±3.13%; p<0.05). A significantly higher IMT was observed at both carotid/femoral sites in H-Group in comparison to C-Group (carotid, 0.53±0.09 vs. 0.47±0.08mm; p<0.05 and femoral, 0.51±0.17 vs. 0.39±0.09mm; p<0.05). While in 10/25 subjects from the H-Group atherosclerotic plaques were detected this was not the case in any of the subjects from C-Group. Inflammation/endothelial dysfunction markers were higher in H-Group (leukocytes 7.0±1.8 vs. 5.6±1.4 $x10^3$/ul; VW 119±29 vs. 93±26 %; fibrinogen 2.82±0.64 vs. 2.29±0.44 g/L; ICAM-1 408±224 vs. 296±95 ng/ml; p<0.05 for all).
Conclusion: In addition to the induction of hypoglycaemia unawareness and an increased risk for severe hypoglycaemia, repeated hypoglycaemia in T1D is associated with a worse prognosis in terms of preclinical atherosclerosis profile. The precise mechanisms explaining this association remains to be clarified.

Pulse pressure predicts all - cause and cardiovascular mortality but not deterioration in kidney function in type 1 diabetic patients

S. Theilade[1], M. Lajer[1], A. Jorsal[1], L. Tarnow[1], H.-H. Parving[2,3], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, [2]Department of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, [3]Faculty of Health Science, Aarhus University, Denmark.

Background and aims: Patients with type 1 diabetes have an elevated risk of early death due to cardiovascular disease (CVD) and development of end stage renal disease (ESRD). The aim of this analysis is to evaluate if pulse pressure (PP) (as an estimate of arterial stiffness) based on office arterial blood pressure predicts mortality, cardiovascular events and progression of diabetic nephropathy in patients with type 1 diabetes.
Materials and methods: A prospective observational follow-up study. The patients were followed for a median (range) of 8.2 (0.0-12.9) years. The cohort consisted of 898 type 1 diabetic patients. Of these, 456 patients had overt diabetic nephropathy (277 men; age (mean ± SD) 42.1 ± 10.5 years, duration of diabetes (mean ± SD) 28.3 ± 8.8 years, glomerular filtration rate (GFR) 76 ± 34 ml/min/1.73 m^2) and were followed with yearly measurement of GFR. The remaining 442 patients had longstanding type 1 diabetes and persistent normoalbuminuria (234 men; age 45.4 ± 11.5 years, duration of diabetes 27.8 ± 10.1 years).
Results: During follow-up 178 (19.8 %) patients died; 109 (12.1%) patients died from CVD causes and 99 (11.0%) patients developed ESRD. Individuals with elevated PP had significantly higher all-cause mortality (hazard ratio per 10 mmHg increase), (HR [95% CI] 1.18 (1.07 to 1.30); *p*=0.001, adjusted for sex, age, duration of diabetes, smoking, diastolic blood pressure, HbA_{1c}, eGFR, cholesterol, and history of CVD). For patients with diabetic nephropathy the adjusted HR for all-cause mortality was 1.16 (1.04 to 1.30) *p*=<0.001. Elevated PP also predicted CVD mortality (adjusted HR 1.27 (1.13 to 1.43) *p<0.001*), and non fatal CVD events (adjusted HR 1.12 (1.01 to 1.25) *p*=0.04). For fatal and non-fatal CVD combined, the adjusted HR was 1.13 (1.04 to 1.24) *p*=0.005). In patients with diabetic nephropathy, elevated PP was associated with higher risk of progression to ESRD (HR (per 10 mmHg increase) 1.27 (1.12 to 1.43) *p<0.001*) but this was not significant after adjustment (HR 1.03 (0.89 to 1.203) and elevated PP was not related to decline in GFR in patients with diabetic nephropathy.
Conclusion: Elevated office pulse pressure (arterial stiffness), predicts all-cause and CV mortality in type 1 diabetic patients. In contrast, office pulse pressure was not associated with progression of diabetic nephropathy.

16

Decreased endothelial progenitor cells associated with poor glycaemic control predict both morphological microvascular and macrovascular impairment in type 1 diabetic children within three years

K. Nagl[1], T. Hoertenhuber[1], M. Fritsch[2], E. Schober[2], O. Schlager[1], M. Gschwandtner[1], A. Willfort-Ehringer[1], C. Margeta[1], R. Koppensteiner[1], G. Schernthaner[3], B. Rami[2], G.-H. Schernthaner[1];
[1]Angiology, Medical University of Vienna, [2]Pediatrics, Medical University of Vienna, [3]Angiology, Rudolfstiftung, Vienna, Austria.

Background and aims: The risk of cardiovascular death before the age of 40 is 20-fold increased in patients with type 1 diabetes mellitus (T1DM) com-

pared to those without. Vascular damage, which might be responsible for the increased risk, can be estimated by bone marrow derived Endothelial Progenitor Cells (EPC). EPC predict cardiovascular morbidity and mortality in patients without diabetes. Recently we have demonstrated that improvement or worsening of glycemic control resulted in indirect proportional changes in EPC in Type 1 diabetic children within one year. So, we asked whether a longer follow-up of these T1DM children would result in morphological changes of the macro- and microvasculature.
Materials and methods: We present data of 74 T1DM children: Gender: 51.4% female; Age: 12.7±0.3 years; Body Mass Index: 20.8±0.4; Glycated Haemoglobin A1c (HbA1c): 7.0-9.1 (range); diabetes duration 4.8±0.4 years (all at time of inclusion). Study visits were inclusion, after 1.0±0.1 and 2.7±0.2 years. EPC (flow cytometry) were measured at all visits.
For estimation of micro- and macrovascular damage two techniques were applied. For macrovascular damage - driven by plaque formation - Carotid Intima Media Thickness (IMT) was assessed by the average of 24 measurements of the vessel walls via high-resolution B-mode ultrasound. For microvascular damage - driven by vessel reactivity - tissue perfusion was investigated by Laser Doppler perfusion imaging (LDPI) and a post-occlusive reactive hyperemia provocation test. For statistical analysis a p-value < 0.05 was considered significant. Results are given in mean±STD or median (25;75 percentile).
Results: EPC at inclusion: 3410/106WBC (2515;4237), EPC at one year: 3334/106WBC (2929;3898). LDPI parameters after 2.7 years: time to absolute peak 9.5s (6.0;21.3), time to baseline: 80.5s (63.0;108.3), Total Time (LDPI-TT): 95.5s (78.0;118.3), Perfusion at absolute peak 1.435 (1.020;2.050), Perfusion at baseline: 0.390 (0.258;0.598), Difference of perfusion at peak and baseline: 1.055 (0.610;1.513). IMT at latest follow-up was 0.285 (0.258;0.350). EPC at earlier time points were significantly predictive for LDPI-TT (R=-0.259; p=0.042) and IMT (R=-0.344; p=0.003). Cross-sectional the following parameters were associated with LDPI-TT: HbA1c (R=0.255; p=0.045); mean-blood-glucose (R=0.331; p=0.013) and aspartate aminotransferase (ASAT) (R=0.315; p=0.015). Associations with IMT were systolic blood pressure (R=0.248; p=0.035); ASAT (R=0.332; p=0.005); alanine aminotransferase (R=0.280; p=0.019); duration of diabetes (R=0.0255; p=0.028).
Conclusion: This is the first study demonstrating an association of EPC with disturbed micro- and macrovascular function in children with Type 1 Diabetes mellitus after a short observation period. Thus, it is most likely that glucose fluctuation with high HbA1c lead from depression of bone-marrow derived EPC to microvascular changes (LDPI), to plaque formation (IMT) and finally to premature cardiovascular disease and death.

17

Early signs of atherosclerosis in diabetic children on intensive insulin treatment: a population based study
H.D. Margeirsdottir[1,2], K.H. Stensaeth[3], J.R. Larsen[4], C. Brunborg[5], K. Dahl-Jorgensen[2,4];
[1]Pediatric department Ullevaal, Oslo University Hospital, Oslo, [2]Faculty of Medicine, University of Oslo, [3]Radiology Department Ullevaal, Oslo University Hospital, [4]Oslo Diabetes Research centre, [5]Centre for Clinical Research Ullevaal, Oslo University Hospital, Norway.

Objective: Young adults with type 1 diabetes are at increased risk of early asymptomatic atherosclerosis and cardiovascular morbidity and mortality are substantially increased in this group of patients. The aim of this study was to evaluate early stages of atherosclerosis and predisposing factors in childhood diabetes compared to age- and sex matched healthy control subjects.
Research design and methods: All children and adolescents with type 1 diabetes, aged 8-18 years in Health Region South-East in Norway were invited to participate in the study (n=800). 40% (n=314) agreed to participate and were compared to118 age-matched healthy controls. Carotid artery Intima Media Thickness (cIMT) and elasticity was measured using standardized methods.
Results: Mean age of the diabetic patients was 13.7 years, diabetes duration 5.5 years and HbA1c 8.4%. 97% were using intensive insulin treatment, 60% insulin pumps. Diabetic patients had more frequently elevated cIMT than healthy controls: 19.5% were above 90th centile of normal healthy controls and 13.1% above 95th centile (p<0.001). Mean cIMT was higher in diabetic boys compared to healthy controls (0.46mm /SD 0.06mm vs. 0.44mm/SD 0.05mm, p=0.04) but not significantly so in girls. There was no significant difference between the groups regarding carotid distensibility, compliance and wall stress. None of the subjects had atherosclerotic plaque formation. Although within the normal range the mean values of systolic blood pressure (SBP), total cholesterol, LDL-cholesterol and ApoB were significantly higher in the diabetic patients than in healthy controls.
Conclusion: Despite short disease duration, intensive insulin treatment, fair glycemic control and no signs of microvascular complications, children and adolescents with type 1 diabetes had slightly increased cIMT compared to healthy controls, the differences being more prominent in the boys.

Colesevelam effects on LDL-C, HbA_{1c}, and GLP-1 in type 1 diabetes mellitus (T1DM)
S.K. Garg, P.J. Ritchie, E.G. Moser, R.S. Gutin, L.B. Crew, J.K. Snell-Bergeon; Barbara Davis Center, University of Colorado Denver, Aurora, USA.

Background and aims: Colesevelam is indicated to lower LDL-C in hyperlipidemia and improve glycemic control in type 2 diabetes (T2DM). The clinical effects in subjects with T1DM have not previously been evaluated.
Materials and methods: This was a double-blind, randomized, investigator-initiated, single center, 12-week pilot study that evaluated 40 adults (36.4±9.4 yr) with T1DM and hyperlipidemia. The study was powered to demonstrate a treatment difference of >10% LDL-C reduction from screening. Subjects were randomized to receive either 3.75 g/day colesevelam (n=20) or placebo (n=20) for 12 weeks. LDL-C and A1c levels were assessed at screening (week -2), baseline (week 0) and every 4 weeks for the duration of the study. All subjects had a 4-hour Boost Plus® meal-challenge test (MCT) at baseline (week 0) and at the end of study (week 12). Study drug was administered at time 0 of the MCT. Incretin levels including GIP and GLP-1 were assessed during the MCT at the following time points (-30, 0, 30, 60, 120, 180 and 240 min). Screening demographics were similar in both treatment groups. Thirty-six subjects (n=18 in each group) completed the study. Compliance for both treatment groups was >88%.
Results: All data presented are from the intent-to-treat population with last observation carried forward. Colesevelam treatment resulted in a significant difference in the least squared mean percent change in LDL-C at 4 weeks (1.7% vs. -12.1%, difference between means 13.84 [95%CI: 2.2, 25.5], p=0.02), and this difference was marginally significant at 8 (p=0.05) and 12 weeks (p=0.08) (Figure 1a). Treatment also resulted in a statistically significant change in A1c from screening at week 4 (-0.19, p=0.04), however this did not remain significant for the study duration (Figure 1b).
Colesevelam resulted in significant median increases in GLP-1 levels during the first 2 hours of the baseline MCT compared to placebo following the first dose of study drug. There was no difference in GLP-1 levels between groups at the week 12 MCT. The GIP levels were similar between the two groups at baseline and 12 week MCTs.
There were no significant differences between or within groups for fasting glucagon, fasting and postprandial glucose, insulin dose, weight or BMI.
Conclusion: Results from this small pilot study suggest that Colesevelam treatment lowers LDL-C in patients with TIDM. While improvements in A1c were observed at week 4, significance was not maintained for the study duration. This effect might be explained by sample size, study duration, and/or chance. The treatment group showed an increase in GLP-1 levels at baseline, which may explain their improvements in A1c at week 4 of this study. However, the effect of Colesevelam on glycemic control in subjects with T1DM requires further clinical study involving a larger number of subjects over a longer duration.

Figure 1a: Mean (± SEM) Percent Change in LDL-C from Baseline (Week 0) (LOCF analysis)

Obestatin and ghrelin bind to human pancreatic islet endothelial cells and inhibit apoptosis in high glucose condition

E. Favaro, I. Miceli, F. Settanni, A. Baragli, R. Granata, G. Camussi, E. Ghigo, P. Cavallo Perin, M.M. Zanone;
Department of Internal Medicine, University of Turin, Italy.

Background and aims: Pancreatic islet microendothelium exhibits unique structural and functional features, in an interdependent physical and functional relationship with the beta cells. Glucose toxicity is not solely restricted to beta cells, but affects also survival of pancreatic islet endothelial cells, thus contributing to beta cell function impairment and cell loss. Studies indicate that gastrointestinal products of the ghrelin gene, obestatin (Ob), acylated ghrelin (AG) and its major circulating form, unacylated ghrelin (UAG) stimulate proliferation and prevent apoptosis of pancreatic β cells and human islets. We aimed to investigate whether these peptides would display survival effects also in human pancreatic islet microendothelial cells (MECs) cultured in high glucose conditions.
Materials and methods: Islet MECs were cultured in 28 mmol/L glucose concentration and, in parallel cultures, stimulated with AG, UAG or Ob (10 nM). Apoptosis was assessed by photometric enzyme immunoassay measuring mono- and oligonucleosomes as an index of DNA fragmentation, by Hoechst staining of apoptotic cells, and by Caspase 3 activity. Western-blot analyses for P-Akt/Akt, P-ERK/ERK pathways and for Bcl-2 (anti-apoptotic gene) and Bax (pro-apoptotic gene) were performed. Blockade of PI3K/adenylyl cyclase/cAMP/protein kinase A signalling was also performed.
Results: Islet MECs express the AG receptor (GRLN-receptor), assessed by RT-PCR analysis, and bind Ob, as assessed by immunofluorescence. In high glucose condition, AG, UAG and Ob inhibited islet MEC apoptosis, activating PI3K/Akt and ERK1/2 phosphorylation and upregulating intracellular cAMP. Further, Bcl-2 expression increased and Bax expression decreased. Blockade experiments counteracted the anti-apoptotic effects.
Conclusions: These data provide evidence that the ghrelin gene-derived peptides bind to, and promote survival of, islet microendothelial cells. The anti-apoptotic effects involve the PI3K/Akt, ERK1/2 and cAMP/PKA pathways. These peptides could therefore represent a potential tool to improve islet vascularization and, indirectly, islet function.

Improved glucose-lowering, insulin-releasing and anorexigenic actions of a novel chemically modified analogue of oxyntomodulin, (D-Ser^2)Oxm[mPEG-PAL]

V.A. Gault, B.D. Kerr, P.R. Flatt;
School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom.

Background and aims: Oxyntomodulin (Oxm) is a 37 amino acid peptide hormone released from intestinal L-cells in response to feeding. Oxm has been shown to exhibit a range of potentially beneficial actions for the alleviation of obesity-diabetes. However, possible exploitation of Oxm-based therapies has been severely restricted due to proteolytic degradation of the peptide by the ubiquitous enzyme dipeptidylpeptidase-IV (DPP-IV). Therefore, the aim of this study was to assess the glucose-lowering, insulin-releasing and anorexigenic actions of novel chemically modified, enzyme resistant analogues of Oxm.
Materials and methods: Oxm, (D-Ser^2)Oxm and (D-Ser^2)Oxm[mPEG-PAL] (all >97% purity) were incubated (0, 2, 4, 8 and 24 h) with DPP-IV (5 mU; n=3) to assess enzyme stability and with clonal pancreatic BRIN-BD11 cells to evaluate acute (20 min; n=8) insulin secretion. Cyclic AMP production (n=4) was examined using GLP-1 and glucagon receptor transfected cells. *In vivo* effect of Oxm analogues on glucose homeostasis, insulin secretion, food intake and body weight were examined in obese diabetic *(ob/ob)* mice.
Results: (D-Ser^2)Oxm[mPEG-PAL] displayed enhanced DPP-IV resistance compared to (D-Ser^2)Oxm and Oxm (13.4 and 1.6-fold, respectively; P<0.001). Oxm, (D-Ser^2)Oxm and (D-Ser^2)Oxm[mPEG-PAL] stimulated cyclic AMP production in a concentration-dependent manner with similar potency in BRIN-BD11 cells with EC_{50} values of 1.84 ± 0.09 nmol/l; 1.81 ± 0.37 nmol/l; and 1.97 ± 1.21 nmol/l, respectively. This was associated with

dual action at GLP-1 and glucagon receptors, although EC_{50} values were 15 to 200-fold greater than respective natural ligands. All peptides significantly stimulated insulin secretion (1.6 to 2.5-fold; P<0.001) in a concentration-dependent and equipotent manner. Acute administration (25 nmol/kg bodyweight) of (D-Ser^2)Oxm[mPEG-PAL] and (D-Ser^2)Oxm reduced plasma glucose (40-50% reduction; P<0.01) and food intake (1.1 to 1.4-fold; P<0.05 to P<0.01), while plasma insulin levels were elevated (1.5 to 1.8-fold; P<0.01 to P<0.001) in *ob/ob* mice. Animals treated with (D-Ser^2)Oxm[mPEG-PAL] and (D-Ser^2)Oxm four or eight hours prior to a glucose load (18 mmol/kg bodyweight) had significantly decreased plasma glucose concentrations (1.2 to 2.0-fold reduction; P<0.05 to P<0.001) compared to Oxm-treated animals. Once-daily administration of (D-Ser^2)Oxm[mPEG-PAL] for 14 days to *ob/ob* mice decreased food intake (1.2 to 1.5-fold; P<0.05 to P<0.001), body weight (1.1 to 1.5-fold; P<0.05 to P<0.01), plasma glucose (30-50%; P<0.05 to P<0.01) and increased plasma insulin (1.4 to 1.5-fold; P<0.01). Furthermore, daily (D-Ser^2)Oxm[mPEG-PAL] administration improved glucose tolerance (1.2 to 1.6-fold; P<0.05 to P<0.001), increased glucose-mediated insulin secretion (1.5 to 1.8-fold; P< 0.05 to P<0.01), pancreatic insulin content (1.5-fold; P<0.001), circulating adiponectin (1.4-fold; P<0.01) and decreased both visfatin (1.3-fold; P<0.01) and triglyceride levels (1.4-fold; P<0.01).
Conclusion: The ability of enzyme resistant (D-Ser^2)Oxm[mPEG-PAL] to improve glucose homeostasis, insulin secretion, satiety, body weight and markers of fat metabolism suggests significant promise for Oxm-based therapies for obesity-diabetes.

21

Synaptotagmin-7 is a positive regulator of glucose-induced GLP-1 secretion

N. Gustavsson, Y. Wang, Y. Kang, W. Han;
Laboratory of Metabolic Medicine, Singapore Bioimaging Consortium, A*STAR, Singapore.

Background and aims: Glucagon-like peptide 1 (GLP-1) is produced by highly specialized gut endocrine L-cells. Despite the demonstrated medical benefits of targeting GLP-1 in the treatment of diabetes, very little is known about the molecular control of GLP-1 secretion. Similar to other endocrine cells, such as islet β-cells, L-cells are electrically excitable, and express ATP-sensitive K-channels and calcium channels. Furthermore, GLP-1 is stored in secretory granules, and GLP-1 granule exocytosis is triggered by increased intracellular calcium levels resulting from stimulation by nutrient, neural and paracrine factors. Although the calcium dependence of GLP-1 granule exocytosis is well established, the identities of calcium-sensing proteins in GLP-1 exocytosis remain elusive. Several members of the synaptotagmin family have been identified as calcium sensors in neurotransmitter and hormone release. In particular, synaptotagmin-7 regulates insulin and glucagon secretion in pancreatic islets, and catecholamine release in chromaffin cells. Considering the functional importance of synaptotagmin-7 in endocrine and neuroendocrine cells, we tested the involvement of synaptotagmin-7 in the regulation of GLP-1 secretion.
Materials and methods: Synaptotagmin-7 expression in intestinal L-cells was tested by immunohistostaining of frozen mouse intestinal sections for synaptotagmin-7 and GLP-1. GLP-1 levels were measured in synaptotagmin-7 knockout mice challenged by glucose ingestion. Glucose-stimulated GLP-1 release was also tested in lentiviral-mediated synaptotagmin-7 knockdown GLUTag cells using cell secretion assay and membrane capacitance measurements. Data are presented as mean ± SEM.
Results: Synaptotagmin-7 was present in L-cells, as demonstrated by its co-localization with GLP-1. Synaptotagmin-7 deletion *in vivo* resulted in a reduction of GLP-1 secretion (683 ± 48 and 360 ± 40 pmol/l/h, control and synaptotagmin-7 knockout, respectively, p < 0.001). Synaptotagmin-7 knockdown GLUTag cells showed a ~50% decrease in glucose-stimulated GLP-1 secretion as determined by cell secretion assay and by membrane capacitance measurements (24 ± 4 and 12 ± 3 fF s^{-1}, control and synaptotagmin-7 KD, respectively, p < 0.05). Synaptotagmin-7 knockdown cells exhibited normal calcium responses, indicating the secretion defects occurred at or downstream of the calcium sensing step.
Conclusion: Taken together, our results demonstrate the importance of synaptotagmin-7 in the regulation of GLP-1 secretion, consistent with its proposed role as a calcium sensor in endocrine and neuroendocrine secretion.

Assessment of the metabolic effects of the gut peptide xenin on insulin secretion, glycaemic control and satiety

N. Irwin, A.I. Taylor, P.R. Flatt, V.A. Gault;
School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom.

Background and aims: Recently significant focus has been directed towards the role of glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1) in the aetiology and treatment of type 2 diabetes. However, peptides co-secreted from the same enteroendocrine cells are less well studied. The present study examines the *in vitro* and *in vivo* metabolic effects of xenin, a peptide co-secreted with GIP from intestinal K-cells.
Materials and methods: Cyclic-AMP production (n=4) and insulin releasing activity (n=8) of xenin was measured in acute (20 min) studies with clonal pancreatic BRIN-BD11 cells. Effects of xenin on membrane potential and intracellular Ca^{2+} were also examined in BRIN-BD11 cells. The glucagon-secreting alpha cell-line, αTC1.9 was used to assess glucagon releasing activity of xenin (n=8). Effects of xenin on plasma glucose and insulin concentrations were examined in overnight fasted normal mice (n=8; 16-20 weeks of age) following subcutaneous (s.c.) injection (25 nmol/kg bodyweight) in combination with glucose (18 nmol/kg bodyweight). To assess duration of biological action, groups of mice were injected with xenin (25 nmol/kg) 30 or 60 min prior to glucose load. For food intake studies, mice were fasted for 12 hours prior to s.c. injection of 50, 100 or 500 nmol/kg xenin. Mice were then allowed free access to normal chow and cumulative food intake monitored.
Results: In clonal BRIN-BD11 cells xenin (10^{-6} M) stimulated insulin secretion at 5.6 (P<0.05) and 16.7 (P<0.01) mmol/l glucose levels compared to respective controls. Xenin also exerted an additive effect (P<0.05 to P<0.01) on GIP and GLP-1 mediated insulin secretion. Xenin did not stimulate cellular cyclic AMP production, alter membrane potential or elevate intracellular Ca^{2+} concentrations. Similarly, *in vitro* glucagon release was not affected by xenin. In normal mice, administration of xenin together with glucose significantly (P<0.05 to P<0.001) reduced individual glucose levels compared to glucose control. Moreover, the area under the curve (AUC) for glucose was significantly lower after administration of xenin compared with glucose administered alone (2.3-fold; P<0.001). This was associated with a significantly enhanced overall glucose-mediated insulin secretory response for xenin compared to glucose alone (1.4-fold; P<0.05). Administration of xenin 30 min previously significantly (P<0.05) decreased individual glucose levels 60 minutes post s.c. glucose injection in normal mice. This was associated with substantially enhanced (2.1-fold; P<0.05) overall insulin release compared to respective controls. Administration 60 min prior to glucose challenge annulled the glucose lowering and insulin releasing effects of xenin. Assessment of effects of xenin on feeding revealed that xenin did not induce a significant change in cumulative food intake in overnight fasted mice when administered at a dose of 50 or 100 nmol/kg. However, when mice received a dose of 500 nmol/kg, xenin induced a 60% decrease (P<0.01) in food intake 30 minutes post injection.
Conclusion: These data indicate that xenin is a short acting peptide with potentially important metabolic effects on blood glucose control. Generation of specific xenin antagonists or longer acting xenin mimetics may be useful in assessing the overall biological consequence of xenin-mediated actions.

23

The effects of brain glucagon-like peptide-1 on peripheral glucose homeostasis

L. Jessen, T.M. Greer, M.E. Iacono, K.S. Ellis, B.M. Paxton, D.A. Sandoval, R.J. Seeley, D.A. D'Alessio;
Department of Medicine, University of Cincinnati, USA.

Background and aims: Glucagon-like peptide-1 (GLP-1) is a gut peptide that promotes glucose homeostasis through regulation of islet-cell hormone secretion, gastric emptying, and hepatic function. GLP-1 is also synthesized in the brain, and recent findings indicate that central GLP-1 plays a role in the regulation of peripheral glucose homeostasis through effects on insulin secretion, hepatic glucose production, and insulin sensitivity. To gain further insights into those processes, we investigated the effects of central GLP-1 receptor (GLP-1r) activation and antagonism on insulin and glucagon release before and during experimental hyperglycemia in rats (*study I*). In addition, we studied the effects of central GLP-1r antagonism on glucose tolerance after meal ingestion in rats (*study II*).

Methods and materials: In *study I*, 30 male Long Evans rats were equipped with third cerebral ventricular (i.c.v.) cannulae and catheters in the carotid artery and jugular vein. After an overnight fast freely-moving animals had continuous i.c.v. infusion with GLP-1 (18 μg/hr), the GLP-1r antagonist Exendin 9-39 (Ex-9) (100 μg/hr), or saline for 125 min; all rats received 8 μl/hr of infusate. Sixty min after the start of i.c.v. infusion, blood glucose was raised to 230 mg/dl with a primed i.v. infusion of 25% glucose. For 65 min the glucose infusion rate was varied to maintain hyperglycemia (230 mg/dl). Arterial blood was sampled during the infusion period every 5-15 min for measurements of blood glucose and plasma levels of insulin, glucagon, and corticosterone. In *study II*, 22 overnight fasted and freely-moving rats with i.c.v. cannulae and i.a. catheters were infused i.c.v. with Ex-9 (100 μg/hr), or saline for 150 min. Thirty min after the start of i.c.v. infusion bottles of Ensure liquid diet (5.5 ml) were made available for 10 min. Because the rats were trained to eat Ensure, they voluntarily consumed the meal within 5 min. After meal ingestion, arterial blood was sampled every 15 min for up to 120 min for measurements of blood glucose.
Results: In *study I*, infusion of i.c.v. GLP-1 increased fasting blood glucose levels (105.5 ± 3.8 vs 91.5 ± 2.9 mg/dl), reduced the average glucose infusion rate required to maintain the glucose clamp (40.0 ± 1.5 vs 54.3 ± 2.8 mg/kg/min), and significantly reduced plasma insulin levels (AUC 14667 ± 1210 vs 20168 ± 1883 pM·min) compared to the saline group ($p < 0.05$ for each). GLP-1-treated rats also had significantly higher glucagon and corticosterone levels ($p < 0.05$ for each) than Ex-9- and saline-treated rats. Surprisingly, there were trends for i.c.v. Ex-9 to reduce insulin levels ($p = 0.0641$) and raise plasma glucagon ($p = 0.1009$). In *study II*, i.c.v. Ex-9 increased blood glucose levels after meal ingestion relative to the saline group, and the area under the curves (4844 ± 233 vs 4150 ± 188 (mg/dl)·min) were significantly higher ($p < 0.05$) in the Ex-9-treated rats compared to the saline group.
Conclusion: These results show that central GLP-1r activation has multiple effects on glucose homeostasis in rats. In the doses used in this study GLP-1 activated the stress response, likely via autonomic-induced suppression and stimulation of insulin and glucagon secretion, respectively. Central GLP-1r blockade using Ex-9 was associated with lower insulin secretion, higher glucagon levels, and higher glucose levels after meal ingestion, supporting a role for brain GLP-1 in the regulation of islet function and peripheral glucose homeostasis.

TGR5-mediated GLP-1 secretion
H.E. Parker, A. Habib, F. Reimann, F.M. Gribble;
Clinical Biochemistry, Cambridge Institute of Medical Research, United Kingdom.

Background and aims: The incretin hormone, GLP-1, is secreted from intestinal L-cells in response to food ingestion, however little is known about how L-cells detect luminal nutrients. Bile acids are also released into the gut lumen in response to nutrients and have been associated with glucose homeostasis and GLP-1 secretion. The aim of this study was to investigate the expression of the bile acid sensitive G-protein coupled TGR5 receptor in primary L-cells and its role in GLP-1 secretion.
Materials and methods: mRNA expression was analyzed by qRT-PCR in L-cells purified from transgenic mice with fluorescently labeled proglucagon-expressing cells. GLP-1 secretion was assayed in primary colonic cultures and GLUTag cells. FRET based $[cAMP]_i$ and ratiometric $[Ca^{2+}]_i$ imaging experiments were performed on GLUTag cells.
Results: TGR5 mRNA expression is highly enriched in L-cells compared to control intestinal epithelial cells. The bile acids deoxycholic acid, lithocholic acid and taurolithocholic acid (TLCA) and a TGR5 agonist increased GLP-1 secretion and enhanced the glucose-triggered response. The GLP-1 response to TLCA and the TGR5 agonist from GLUTag cells was attenuated with TGR5 siRNA treatment. Consistent with signaling via G_s coupled pathways, the TGR5 agonist and TLCA elevated $[cAMP]_i$ in GLUTag cells. The TGR5 agonist triggered $[Ca^{2+}]_i$ and enhanced glucose-triggered $[Ca^{2+}]_i$ responses, consistent with previously observed responses of GLUTag cells to elevated cAMP.
Conclusion: Primary L-cells express the bile acid sensitive TGR5 receptor, which may contribute to the incretin response via the elevation of $[cAMP]_i$ and $[Ca^{2+}]_i$. The synergistic stimulation of GLP-1 release may be possible by combined activation of GPCRs and glucose-sensing pathways.

Near-normoglycaemia prevents the development of polyneuropathy, a 24-year prospective study from the diagnosis of type 1 diabetes
D. Ziegler[1,2], M. Roden[1,2];
[1]Institute for Clinical Diabetology, German Diabetes Center, [2]Department of Metabolic Diseases, University Hospital, Düsseldorf, Germany.

Background and aims: Whether near-normoglycaemia instituted from the diagnosis of type 1 diabetes onward may completely or partially prevent the development of polyneuropathy and autonomic neuropathy has not been previously determined. To address this issue we conducted a long-term prospective study.
Materials and methods: We examined 32 newly diagnosed Type 1 diabetic patients (21 male, 11 female) aged 12-36 (mean±SEM: 20.3±1.0) years who were followed over 24 years. Motor and sensory nerve conduction velocity (MNCV, SNCV), vibration perception threshold (VPT), thermal detection thresholds (TDT), coefficient of R-R interval variation at rest (CV), and clinical assessment were performed at the time of diagnosis, after 3 and 12 months, and thereafter biennially for up to 24 years.
Results: During the 24-year period, 11 patients had mean HbA1c levels <7.0% according to the current guidelines (6.5±0.1%; Group 1), whereas 21 patients had mean HbAc levels ≥7.0% (8.3±0.2%; Group 2). Within the first 4 years, reduced sensory NCV and cardiac autonomic function, rather than elevated VPT and TDT were observed as markers indicating initial nerve dysfunction in Group 2 as compared with Group 1. After 24 years, MNCV was significantly faster in Group 1 than in Group 2 in the median (55.5±1.6 vs 48.9±1.6 m/s), ulnar (56.5±1.5 vs 49.3±1.7 m/s), and peroneal nerve (44.7±1.6 vs 36.8±2.5 m/s) and SNCV was faster in the median (53.6±1.6 vs 45.5±2.8 m/s), ulnar (54.7±1.8 vs 43.0±3.9 m/s), and sural nerve (44.5±1.8 vs 35.5±2.6 m/s) (all $p<0.05$). In Group 1 the decline in peroneal MNCV and sural SNCV was -0.1 and -0.2 m/s/year, respectively, comparable to a non-diabetic control group (n=15). In contrast, Group 2 showed corresponding losses of -0.4 and -0.5 m/s/year, respectively. Impairment in VPT, TDT, and CV also developed at a significantly faster rate in Group 2 than in Group 1 (all $p<0.05$). After 24 years, none of the patients in Group 1, but 12 (57%) of those in Group 2 developed clinical polyneuropathy confirmed by NCV. Two patients in Group 2 died during the period studied.
Conclusion: Near-normoglycaemia maintained from the diagnosis of type 1 diabetes over the next 24 years effectively prevented the development of clinical polyneuropathy, a 3-fold faster annual hyperglycaemia-induced decline in NCV, and deterioration in sensory and cardiac autonomic function, whereas poor glycemic control constituted the paramount permissive factor contributing to the evolution and progression of neuropathy in the majority of type 1 diabetic subjects.

26

A double-blind randomised study comparing the effects of pregabalin, duloxetine and amitryptiline on aspects of neuropathic pain, mood and sleep in diabetic subjects with painful neuropathy
L. Gribble[1], R. Gouni[2], M. Eriksson[1], J. Boyle[1], D. Kerr[2], D. Coppini[3];
[1]Clinical Research Center, Surrey University, Guildford, [2]Royal Bournemouth Hospital, [3]Poole Hospital NHS Trust, United Kingdom.

Background and aims: The mechanisms of painful diabetic neuropathy are poorly understood and drug treatment if often unpredictable, with both an overall disappointing response rate, and generally poor patient tolerance to long term use. The main aim of the study was to try and identify which commonly used agent may have most beneficial effect on both pain and quality of life.
Materials and methods: Subjects with neuropathic pain (Leeds Assessment of Neuropathic Symptoms and Signs (LANSS)>12) were recruited from 2 hospital diabetes clinics. Subjects were required to have a score >25 on the Mini Mental State Exam (MMSE). The 36 day study (placebo day 1-8) had a double blind, parallel groups design with three treatment arms consisting of either amitriptyline (50mg followed by 75mg), pregabalin (300mg followed by 600mg) or duloxetine (60mg followed by 120mg). Subjects previously on any of neuropathic medications had an appropriate wash out period prior

to study entry, and all other analgesic medications were withdrawn where possible. Subjects were studied on days 6-8, 20-22, and 34-36. 65 of 83 (78%) randomised subjects (mean age 65 (38-83) years, 69% male), completed the study. Subjects completed daily diaries for pain (brief pain inventory (BPI) and the Short-form McGill visual analogue scale (VAS).
Results: In all three groups there was a significant decrease ($p < 0.05$) in pain severity (BPI severity and VAS) over time but there was no difference between the three treatments in reducing pain severity. Decrease in pain severity was significant in all treatment arms from placebo to low dose ($p<0.05$ for pregabalin and amitriptyline, $p<0.01$ for duloxetine), but no significant additional treatment benefit was seen in any group with increased drug dosage. Patients on duloxetine showed a significant decrease in pain interference over time, both from placebo to low dose, and from low dose to high dose ($p < 0.05$), and an improvement in BPI mood (<0.05). All three study drugs doses improved pain interference on sleep as assessed by the BPI ($p<0.05$) with no significant difference between any of the treatments.
Conclusion: Deciding on the ideal treatment drug for painful diabetic neuropathy remains an enigma, with seemingly little difference between conventional drugs on pain outcomes. Duloxetine, amitryptiline and pregabalin all improved subjective pain as assessed by the BPI and VAS and pain interference on sleep with no significant difference between any of the treatments. With duloxetine there was also a reduction in pain interference and mood.

New insights into central pain processing in painful diabetic neuropathy: a functional magnetic resonance imaging study
D. Selvarajah[1], I.D. Wilkinson[2], M.D. Hunter[3], A. Shankar[4], E. Cachia[2], I. Tracey[5], S. Tesfaye[1];
[1]Diabetes and Endocrinology, Royal Hallamshire Hospital, Sheffield, [2]Academic Unit of Magnetic Resonance Imaging, University of Sheffield, [3]Department of Psychiary & Neuroimaging, University of Sheffield, [4]Diabetes and Endocrinology, University of Sheffield, [5]Department of Clinical Neurology, Oxford University, Oxford Centre for Functional MRI of the Brain, United Kingdom.

The exact pathophysiology underlying painful-diabetic peripheral neuropathy (DPN) remains unknown although several peripheral and central mechanisms have been postulated. An investigation of the brain's responses to acute painful stimuli may provide insights into the impact of the neuropathic process on nociceptive processing, thereby identifying key areas possibly affected by DPN.
Methods: 6 subjects with Painful-DPN underwent detailed neurophysiological assessments and functional magnetic resonance imaging (fMRI). All subjects had severe neuropathic pain below the knees. Before fMRI, heat pain was applied to the anterior thigh (control region) and dorsum of the foot to establish the level of noxious thermal stimulus which elicited a response of ≥7/11 point Likert scale. This was repeated inside the scanner alternating between pain-free baseline and noxious stimulus in a box-car design. Images were analysed using statistical parametric mapping SPM5. Following spatial preprocessing, first-level functional images were produced comparing baseline and heat pain states. Images were combined at the group level in a random effects model.
Results: Painful stimuli delivered to the neuropathic foot site were associated with significantly *reduced* activation in the left posterior insular cortex compared with painful stimuli administered to the thigh (stereotactic coordinates: x=-38, y=-20, z=16; peak t[5]=12.57; 55 voxels exceeded height threshold $p<0.01$, uncorrected). Conversely, compared with painful stimuli delivered to the thigh, painful stimuli administered to the neuropathic foot site evoked significantly *greater* brain activation in the right medial prefrontal cortex (x=12, y=36, z=34; t[5]=9.11; 42 supra-threshold voxels).
Discussion: The posterior insular cortex serves as an interface between afferent processing mechanisms and more cognitively orientated mechanisms. Relative lack of activation in this region during acute noxious thermal stimulation of the foot suggests a complex alteration of the pain experience in Painful-DPN. Prefrontal cortex is associated with high-order cognitive and emotional functions. Increased activation in this region during noxious stimulation of the foot suggests greater emotional/cognitive involvement of acute pain processing in Painful-DPN. These preliminary results suggest that painful stimuli delivered to neuropathic and symptom-free sites in DPN evoke differential activation of distinct cortical regions, which could reflect abnormal central pain processing.

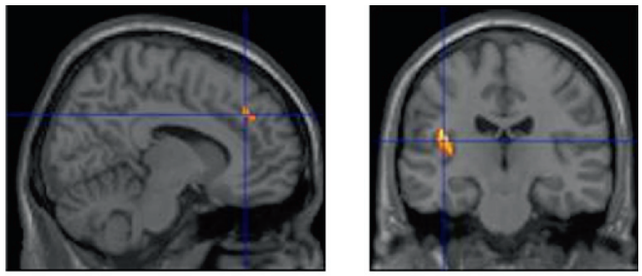

Figure 1: Greater brain activation foot vs. thigh right medial prefrontal cortex (a) and thigh vs. foot left posterior insular cortex (b).

Obstructive sleep apnoea is independently associated with peripheral neuropathy in patients with type 2 diabetes
A.A. Tahrani[1], A. Ali[2], S. Begum[2], K. Dubb[1], S. Mughal[2], B. Jose[2], M. Piya[1], D. Banerjee[2], A.H. Barnett[1], M.J. Stevens[1], S. Taheri[1,2];
[1]University of Birmingham, [2]The Biomedical Unit, United Kingdom.

Background: Obstructive sleep apnoea (OSA) is prevalent in patients with type 2 diabetes (T2D). Since OSA and diabetes complications share common oxidative stress and inflammatory mechanisms, we hypothesized that there is a relationship between OSA and diabetic peripheral neuropathy (DPN).
Methods: T2D patients were recruited randomly from the outpatients of a tertiary diabetes centre in the UK. Patients with known respiratory disorder (including OSA) were excluded. DPN was diagnosed using the Michigan Neuropathy Screening Instrument (MNSI) (a score ≥7 on the questionnaire (MNSIq) or > 3 on the examination (MNSIe) was considered consistent with DPN). OSA was assessed using home-based portable multi-channel respiratory monitoring (Alice PDX, Philips Respironics, USA). An apnoea-hypopnea index (AHI) ≥ 5 events/hour was diagnostic of OSA (OSA+). Data are presented as median (IQR).

Table 1: Participants' characteristics in relation to OSA status. P value calculated using the Mann-Whitney U in scale variables and the Chi-square test.

	OSA+	OSA-	P value
Age (years)	61 (54-66)	54 (44-61)	0.006
Diabetes duration (years)	12.5 (6.0 -17.0)	10.5 (6.0-16.0)	0.42
BMI (kg/m^2)	33.4 (30.9-37.2)	30.3 (27.4-35.8)	0.005
Waist circumference (cm)	112.8 (106.8-123.0)	106.0 (94.8-117.4)	0.005
Neck circumference (cm)	42.3 (39.0-45.1)	38.5 (36.8-41.8)	<0.001
HbA1c (%)	7.8 (6.8-9.5)	7.8 (6.9-8.8)	0.81
Total cholesterol (mmol/l)	3.7 (3.2-4.2)	3.7 (3.4-4.5)	0.26
Triglycerides (mmol/l)	1.8 (1.2-2.5)	1.6 (1.1-2.8)	0.87
BP-systolic (mmHg)	130 (124-137)	126 (114-137)	0.04
BP-diastolic (mmHg)	78 (71-84)	79 (71-83)	0.74
Male (%)	68.5	50.7	0.04
Smoker (%)	5.5	19.7	0.012
Alcohol (%)	30.1	9.9	0.005
Insulin (%)	59.7	43.7	0.066
GLP-1 analogue (%)	14%	7%	0.28
Statins (%)	87.5	85.9	0.81
Fibrates (%)	2.7%	5.6%	0.21
ACE inhibitors (%)	47.2	43.7	0.74
Diuretics (%)	43.1	22.5	0.012
Anti-platelet (%)	79.2	63.4	0.043

Results: 143 patients were included; 50% had OSA and 46% had DPN. Participants' characteristics in relation to OSA status are summarised in Table 1. The prevalence of DPN was significantly higher in OSA+ (compared to OSA-) patients (58% vs. 32%, p=0.003). In logistic regression model (goodness to fit test p=0.002, R^2=0.34-0.46), OSA+ remained a significant predictor of DPN (OR: 3.08, 95%CI 1.01-9.38, p=0.048) after adjusting for BP, HbA1c, total cholesterol, triglycerides, diabetes duration, smoking status, alcohol intake, gender, renal function, BMI, age and the use of GLP-1 analogues, insulin, oral anti-diabetes therapy, lipid lowering therapy, anti-hypertensives and anti-platelets. Other significant predictors in the model included age (OR: 1.08, 95%CI 1.004-1.15,p=0.039), BMI (OR: 1.15, 95%CI 1.05-1.26, p=0.003), not taking a statin (OR:4.71, 95%CI 1.12-19.86, p=0.035) and total cholesterol (OR: 2.43, 95%CI 1.25-4.71, p=0.009). Log (AHI) correlated significantly with the MNSIe score (r=0.22, p=0.012). This remained the case (r=0.23, p=0.015) after adjusting for age, diabetes duration, BP, HbA1c, triglycerides, total cholesterol and renal function.
Conclusion: We describe a novel association between OSA and DPN in patients with T2D. The severity of OSA correlated significantly with the severity of DPN based on MNSIe. Planned studies aim to confirm our findings and overcome the limitations of the current study.

Effects of genetic versus environmental factors on cardiovascular autonomic function and baroreflex sensitivity: a twin study
J. Osztovits[1], T. Horváth[2], R. Steinbach[3], Á. Jermendy[3], L. Littvay[4], Á. Tárnoki[3], D. Tárnoki[3], J. Métneki[5], M. Kollai[2], G. Jermendy[1];
[1]3rd. Department of Internal Medicine, Bajcsy Zsilinszky Teaching Hospital, [2]Institute of Human of Human Physiology and Clinical Experimental Research, Semmelweis University, [3]Semmelweis University, [4]Central European University, [5]National Centre for Healthcare Audit and Inspection, Budapest, Hungary.

Background and aims: Cardiovascular autonomic neuropathy (CAN) and impaired baroreflex sensitivity (BRS) can often be detected in patients with diabetes mellitus. CAN and BRS are independent predictors of cardiovascular morbidity and mortality. The heritability of cardiovascular autonomic function is not fully understood. The aim of the current study was to determine the effects of genetic and environmental factors on cardiovascular autonomic function and BRS.
Material and methods: Healthy adult twin pairs (n=101; 63 monozygotic [MZ] and 38 dizygotic [DZ] pairs; 72.5% women, 27.5% men; age: 44.3±15.5 years) were investigated. Anthropometric variables (weight, height, waist circumference) were registered, body mass index (BMI) was calculated, serum metabolic markers were measured; furthermore lifestyle and environmental background characteristics were evaluated by using questionnaires. Linear and spectral indices of heart rate variability (HRV) and BRS were determined by non-invasive methods. In resting supine position, RR interval was derived from ECG recordings, and continuous radial artery pressure was monitored simultaneously by applanation tonometry for 10 minutes. All parameters were adjusted for age and gender. Pearson correlation coefficients were calculated per zygosity (intraclass correlations) in order to determine the extent to which MZ twin pairs are more similar than DZ pairs. In addition, heritability model analyses were used for characterizing additive genetic, shared (common) and unshared (individual) environmental influences.
Results: There was no difference between BMI and waist circumference in MZ versus DZ pairs (25.9±4.9 vs. 25.8±5.9 kg/m^2, p=0.642; and 88.2±14.6 vs. 88.4±16.0 cm, p=0.986, respectively). The intraclass coefficients of correlation (r values) were low for HRV and BRS indices, in both MZ and DZ twins (LF [HRV power in low frequency range) MZ=0.140 vs. DZ=0.401; HF [HRV power in high frequency range): MZ=0.299 vs. DZ=0.225) and the heritability model analysis showed high percents of unshared environmental contribution (LF=0.816; HF=0.701). The intraclass coefficients of correlation (r values) for BRS were low in both MZ and DZ twins (BRSseq+ index: MZ=0.281 vs. DZ=0.279; BRSseq- index: MZ=0.456 vs. DZ=0.064) and the heritability model analysis showed high percents of unshared environmental contribution (BRSseq+ index=0.719; BRSseq- index=0.554). No significant changes were found after adjusting parameters for BMI values.
Conclusion: Unshared (individual) environmental but not inheritable factors have substantial influence on cardiovascular autonomic function and BRS. Accordingly, all modifiable environmental factors should appropriately be treated in order to prevent or decrease cardiovascular autonomic dysfunction and impaired BRS in patients with diabetes mellitus.

Role of depressed cardiac autonomic activity in the impairment of heart rate recovery after exercise in diabetic patients
M. Vivier, M. Nguyen, P. Weinmann, E. Cosson, P. Valensi;
Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, Bondy, France.

Background and aims: The heart rate (HR) profile during exercise and recovery is a powerful predictor of sudden death in coronary patients and in subjects without clinically detectable cardiovascular disease. A defect of HR recovery after the termination of an exercise has been suggested to result from an impairment of the ability to increase vagal and sympathetic activity rapidly. Alterations of vago-sympathetic activity might contribute to impair HR profile during exercise and recovery in diabetic patients. The aim of this study was to examine the role of depressed cardiac autonomic activity in the impairment of HR profile during exercise and recovery in diabetic patients.
Materials and methods: We included 165 type 2 diabetic patients, 98 men and 67 women, mean age 58 yrs and diabetes duration 12.5 yrs. All of them had at least one additional risk factor (including 132 patients with hypertension) and were prospectively screened for silent myocardial ischemia (SMI), defined as an abnormal stress myocardial scintigraphy. The stress exercise test was performed on a cycle ergometer, and HR was measured at rest, at exercise peak (HRmax) and after 2 minutes of recovery. Cardiac autonomic neuropathy (CAN) was assessed using standard tests (deep-breathing, lying-to-standing and Valsalva) and was defined by at least one abnormal test.
Results: SMI, peripheral vascular disease, peripheral neuropathy and CAN were detected in 28%, 5%, 33% and 77% of the patients, respectively. HR at rest, HRmax and HR at recovery did not differ significantly in patients with or without CAN, peripheral neuropathy or vascular disease or SMI. In the total population HR decrease at recovery (% decrease from HRmax) correlated significantly with HR acceleration (% increase from rest) (r=0.532, p<0.0001). HR acceleration correlated significantly with age and HR at rest (p<0.001), and there was a trend to lower values in patients with peripheral neuropathy but HR acceleration did not differ significantly in patients with or without hypertension, peripheral vascular disease, SMI or CAN. In multivariate analysis HR acceleration was significantly associated (p=0.03) with peripheral neuropathy independently of age and HR at rest. HR decrease at recovery was slightly higher in women than in men (32±9% vs 29±10%, p=0.08), and slightly lower in patients with than in patients without CAN (30±11 vs 34±8%, p=0.143) and in those with 2 or 3 abnormal CAN function tests than in those with no or one abnormal test (29±11 vs 32±10%, p=0.148) but did not differ significantly in patients with or without hypertension, peripheral neuropathy or vascular disease or SMI. In multivariate analysis the association of HR decrease at recovery with CAN was significant (p<0.001), independently of age, gender and HR at rest. In the patients free of SMI for whom exercise was not stopped prematurely, HR decrease at recovery was significantly lower in those with CAN (p=0.02), in particular in those with 2 or 3 abnormal CAN function tests (p=0.02).
Conclusion: In high-risk but asymptomatic type 2 diabetic patients, peripheral neuropathy and CAN are major determinants of HR acceleration during exercise and HR recovery, respectively.

OP 6 Ethnic and psychosocial disparities in diabetes

31

Glycaemia management of minority participants in ACCORD

J. Calles-Escandon[1], L. Light[1], L. Lovato[1], A. Getaneh[2], D. Simmons[3], J. Kirk[1], D. Bonds[4], M.A. Banerji[5], J.B. Green[6], L. Menon[1], A. Moogali[1], R.M. Bergenstal[7];
[1]Wake Forest Univ, Winston-Salem, [2]Columbia Univ, New York City, [3]Univ of Arkansas, Little Rock, [4]NHLBI, Washington, [5]State Univ, New York, Brooklyn, [6]Duke Univ, Durham, [7]ADA, Alexandria, USA.

Background: Epidemiologically, African Americans (AA) and Hispanic-Americans (H) with type 2 diabetes (T2DM) have higher A1C levels than Whites (W). This difference might be due to socioeconomic factors, differences in health care access, and/or biological differences. Clinical trials may reduce the influence of some of these factors by provision of free medical care, education and medications. ACCORD trial tested the hypothesis that a therapeutic strategy targeting an A1C <6% (INT) compared to one targeting 7 to 7.9% (STD) would reduce cardiovascular events in patients with T2DM. In this post-hoc analysis of ACCORD we use A1C values to evaluate if equalization of access to health care reduces the variation in A1C across W, AA and H.
Methods: Baseline characteristics for each intervention arm were compared using ANOVA (continuous variables) and Chi-square (dichotomous variables)**.** The proportion of participants who ever reached A1C <=6.5%, for the INT and <=7.9% for STD, and among those reaching these levels, the proportion whose A1C increased to >6.5% / >7.9% at any subsequent visit, was calculated by race/ethnicity. Since most of the change in A1C in ACCORD was achieved during the first year, repeated measures models were created for A1C levels at 4-, 8-, and 12-month visits, stratified by glycaemia intervention arm. A sequential modelling approach tested the significance of effect of race/ethnicity on A1C in these models.
Results: Of 10, 251 participants, 6,393 were W, 1953 AA, and 737 H. Baseline A1C was higher for H (8.4% INT, 8.6% STD) and AA (8.5% both arms) compared with W (8.2% both arms, P <0.001 for both arms.). In the INT arm 81% of W achieved A1C <6.5% compared with 68% AA and 70% H. In the STD arm 96% W compared with 91% AA and 90% H achieved A1C <7.9%. W in INT were less likely to ↑ A1C once target was achieved (63%) than AA(74%) or H (76%); rates were similar in the STD (W 71%, AA 73%, H 67%). Mean A1C was higher at the 12 month visit in AA and H vs. W (7.8%, 7.8%, and 7.6% respectively for STD; 6.8%, 6.7%, and 6.5% respectively for INT). However, mean insulin use (units/day or units/kg/day), as well as the mean number of oral hypoglycemic agents (OHA), was similar for all groups in both arms. When baseline characteristics were accounted for in regression models, race/ethnicity remained as a significant predictor of differences in A1C for both INT (p<0.001) and STD (p=0.001).
Discussion: With similar access to diabetes care and equal use of insulin and OHA, a large percent of AA and H achieved similar A1C compared with W. However, mean A1C remained different. In regression models baseline differences in A1C, BMI, duration of diabetes, and socio-demographic differences did not alter the observation nor did on-study insulin quantity or OHA. The major strengths of the study are the large number of H and AA participants with T2DM with equal access to diabetes care as W. Weaknesses of this study include the "secondary" nature of this analysis and the lack of pre-specified culturally sensitive patient education and management. It remains to be determined whether the remaining mild differences in A1C between these ethnic groups are due to cultural or biological factors or both.

Screening for type 2 diabetes mellitus identifies a major burden of modifiable cardiovascular risk

B. Thiagarajan Srinivasan[1], D.R. Webb[1], M.J. Davies[1], S.G. Griffin[2], B.J. Echouffo-Tcheugui[2], N.J. Wareham[2], S. Campbell[3], L.G. Gray[1], K. Khunti[3];
[1]Cardiovascular Sciences, University of Leicester, [2]MRC Epidemiology Unit, Institute of Metabolic Science, Cambridge, [3]Department of Health Sciences, University of Leicester, United Kingdom.

Background and aims: Population screening for Type 2 Diabetes (T2D) enables diagnosis earlier in the disease trajectory than existing approaches. If followed by sustained multifactorial intervention, vascular outcomes should theoretically improve. It is largely unknown whether population-based screening for T2D identifies cases at increased yet modifiable cardiovascular disease (CVD) risk. We aimed to compare baseline characteristics, modelled 10 year risk and estimated CVD risk reduction of two newly diagnosed T2D populations: one-screen-detected and the other clinically diagnosed.
Materials and methods: The screen detected cohort (LEADER) is an amalgamation of two population-based programmes of screening for T2D by OGTT (n=309): (i) STAR which used targeted screening of those with at least one risk factor for T2D, (ii) ADDITION-Leicester a universal screening study and RCT of CVD risk intervention in screen-detected T2D.The clinically diagnosed group, representative of T2D cases in UK clinical practice was derived from an RCT of structured education (DESMOND) (n=824). In those without prior CVD, an ethnicity adjusted Framingham equation (Ethrisk) was used to estimate 10-year CVD risk. The absolute risk reduction achievable and its plausible range were predicted using relative risk reductions for individual therapies from published trials and sensitivity analysis.
Results: Screen-detected people had statistically significant higher levels of systolic and diastolic blood pressure and total cholesterol with lower levels of BMI and HbA1c compared to those who were clinically diagnosed. Medication use was significantly higher in those who were conventially diagnosed: anti-hypertensives 60% vs. 44%, lipid lowering 41% vs. 21%, aspirin 27% vs. 16%, all p<0.0001. Mean 10 year CVD risk was significantly higher in the screen detected group (21.1% vs. 16.8%, p<0.0001). By commencing multifactorial therapy in this high risk screen-detected group the absolute risk reductions (ARR) achievable range from 4% to 10% (related to numbers needed to treat (NNT) of 10 to 25), with higher risk reductions being seen in those from a white European background compared to South Asians.
Conclusion: T2D cases identified through population screening are at high risk of CVD. At detection, this adverse CVD risk profile is often untreated, but appears potentially modifiable with existing preventative treatments. Lower estimated CVD risk reduction in south Asians suggests alternative factors may be important in determining risk within this group.

Estimation of absolute CVD risk reduction in screen detected T2D using Ethrisk

	ARR (Range)	NNT
No added effect treatment (Lipid Lowering therapy)	4.0 (2.7-5.2)	25
Additive effect: glucose, lipid and bp lowering therapies	8.5 (7.3-9.5)	12
Additive effect: glucose, lipid bp lowering therapies and aspirin	10 (9.3-11)	10
White Europeans	n=154	
No additive effect	4.6 (3.1-6.1)	21

Dispelling myths about social disparities in diabetes-related complications and mortality: Diabetes Study of Northern California (DISTANCE)

A.J. Karter[1], D. Schillinger[2], A.S. Adams[1], H.H. Moffet[1], J. Liu[1], N. Adler[3];
[1]Division of Research, Kaiser Permanente, Bainbridge Island, [2]School of Medicine, University of California, San Francisco, [3]Department of Psychiatry, University of California, San Francisco, USA.

Background and aims: In contrast to studies of health disparities in the UK and Europe which focus primarily on social class, US studies have focused much more attention on disparities associated with race/ethnicity and "vulnerable minorities". Few studies have considered how race/ethnicity and social class each relate to specific health problems. In diabetes, educational disparities in related outcomes (complications and mortality) are under-studied.

We evaluated the size and direction of educational and race/ethnic disparities in diabetes-related complications and mortality.
Material and methods: We followed a cohort of 64,419 fully-insured, patients with diabetes (19 years or older) with uniform access to integrated care (Kaiser Permanente) for 10 years (1996-2005; ~463,800 person-years). Hazard ratios (HR) were estimated from age and sex-adjusted Cox proportional hazard models (time to incident event), specified separately for all-cause mortality (MORT) and incident nonfatal and fatal complications (myocardial infarction (MI), congestive heart failure (CHF), stroke, end stage renal disease (ESRD), lower extremity amputation (AMP), after excluding those with prevalent history for each complication model.
Results: There was a significant, stepwise relationship between education and diabetes endpoints, with a 20-60% greater comorbidity and mortality (e.g., HRs for amputation: 1.6, 1.4, 1.3, 1.0 and HR for mortality: 1.3, 1.2, 1.1, 1.0 for less than high school (HS), HS graduate, some college and college grad respectively) burden for those with less than a high school education compared to college graduates. Asians had markedly lower rates of amputation (HR: 0.4 relative to Whites) than the other groups and together with Latinos, had the lowest overall morbidity and mortality rates. African Americans had the highest CHF, stroke, ESRD and amputation rates, although not significantly different than whites. Whites had the highest incidence of MI and mortality, but the lowest incidence of ESRD. Estimates were essentially unaltered after further adjustment for type of diabetes, duration of diabetes, diabetes medications, hypertension, dyslipidemia, CKD category based on GFR, albuminuria, hemoglobin A1c, prevalent MI, stroke, CHF, ESRD, and amputation.
Conclusion: Contrary to convention wisdom, there are no race/ethnic groups that are consistently at highest (or lowest) risk for diabetes complications. In contrast, low educational attainment was consistently associated with poorer health across all outcomes, independent of race/ethnicity, and may be explained by risk factors held in common for all complications (e.g., smoking, inadequate health literacy, poor medication adherence and cost barriers), thus suggesting potential candidates for interventions that could reduce disparities for combined endpoints. Future efforts to reduce social disparities among patients with diabetes should pay greater attention to socioeconomic/social class disparities, while maintaining existing attention to ethnic disparities.

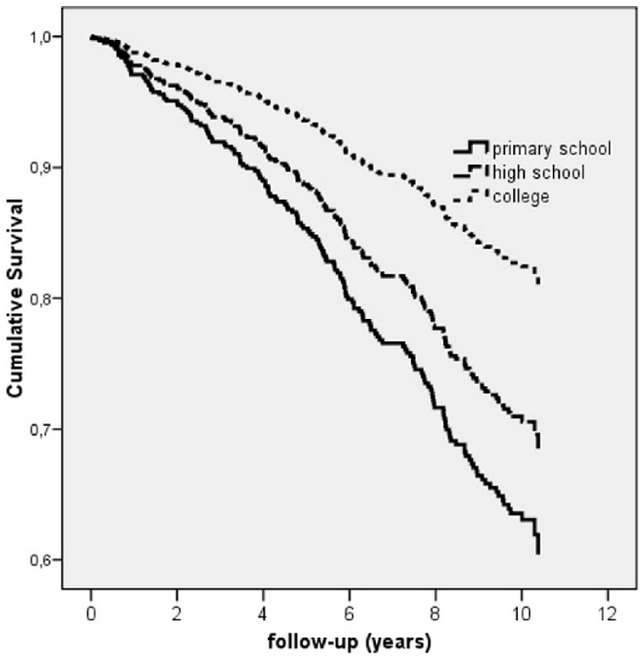
Educational disparities and the risk for mortality in patients with type 2 diabetes
N. Kleefstra[1,2], G.W.D. Landman[1], I. Drion[1], K.J.J. van Hateren[1,3], H.J.G. Bilo[1];
[1]Diabetes Centre, Isala Clinics, Zwolle, [2]Medical Research Group, Langerhans, Zwolle, [3]Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: The relationship between socioeconomic status and mortality is clear and has also been established in studies in type 2 diabetes (T2DM). The relationship between educational level and mortality in T2DM has recently received attention in a study from the United States (US). We studied this relationship in a Dutch cohort of T2DM patients.
Materials and methods: This study is part of the Zwolle Outpatient Diabetes project Integrating Available Care (ZODIAC) study, in which patients with T2DM, treated in primary care, were enrolled. The ZODIAC study started in January 1998. Data on educational level were first collected on 19 May 1998, however. From this date on 858 patient were included in 1998, and educational level was known for 648 (76%) patients. The survival status (dead or alive) for each patient was recorded in January 2009. The relation between mortality and educational levels were studied with a Cox proportional hazard model. Educational level was divided in 3 categories: no education beyond primary school, high school, and college. Potential confounders for which was corrected were: age, sex, body mass index, smoking status (yes/no), macrovascular complications (yes/no), diabetes duration and working status.
Results: After a median follow-up time of 9.7 years, 367 out of 858 patients had died, the cause of death was known for 350 patients: 40% died from cardiovascular disease and 23% died from malignancies. Compared to patients who finished primary school, patients who had gone to college, had a Hazard Ratio (HR) of 0.42 (95% CI 0.19-0.91) for total mortality, and patients who had gone to secondary school had a HR of 0.75 (95% CI 0.51-1.11) for total mortality (see figure 1). No significant relationship between educational level and cardiovascular and cancer mortality was found.
Conclusion: Educational level was associated with total mortality even after adjustment for working status. Patients with no education beyond primary school had an increased risk for total mortality compared to those who had gone to college. The risk of mortality differs substantially according to educational level among persons with T2DM in the Netherlands and confirms the results recently found in the US.



35

Socio-economic impact on the quality of diabetes mellitus type 2 care: can we improve the outcomes?
M. Bernas, J. Tatoń, Z. Szczeklik-Kumala;
Department of Internal Diseases and Diabetology, Medical University of Warsaw, Poland.

Background and aims: According to the European Commission, the executive body of the European Union, "social and economic deprivation involves persons, families or populations whose economic, cultural and social conditions are limited to a level below the minimal life standard accepted in their country of domicile." This definition embraces large populations with diabetes mellitus type 2. In order to counteract the impact of deprivation and poverty on treatment of diabetes mellitus in those populations, the specific patterns and mechanisms of poor socio-economic status existing in the real world of diabetes mellitus care should be objectively delineated. Therefore, the study presented below was conducted.
Materials and methods: Using standardized socio-medical and economic questionnaires, the study was conducted on a cohort of 1,050 persons with diabetes mellitus type 2 hospitalized in 2005-2008 in the public diabetological centre (Department of Diabetology, Bródnowski Hospital, Warsaw). Their socio-economical and health status characteristics were diagnosed in a standardized way using appropriate questionnaires and a grading system containing four categories: 1, economic; 2, psychological and social; 3, educational, and 4, medical.
Results: In the cohort of 1,050 hospitalized diabetic type 2 persons under study, 282, or 29%, were found to have social, economical or psychological and educational deprivation and poverty not meeting local minimal life standards as defined by the Central State Statistical Office. The specific components of the deprivation and poverty standards that were analyzed were: 1, character of family and social support; 2, profession and employment; 3, level of formal education; 4, monthly income, help of social organizations; 5, fear and depression; 6, practice of self-control, and 7, frequency of planned medical outpatient visits. Using these parameters, the existence or non-existence of deprivation and poverty was diagnosed and produced two groups of patients: 1, those afflicted by deprivation and poverty (282 out of 1,050 cases, or 27.9%), and 2. those not afflicted (768 out of 1,050 cases, or 72.1 %). The medical diagnoses in both subgbroups are presented below.
Conclusion: The social, economical, psychological and educational deprivation and poverty acts as a separate risk factor for the level of diabetes

mellitus type 2 control. It is reflected by the differences in morbidity, due to the chronic complications of diabetes mellitus, and also by the existence of additional chronic diseases associated with diabetes mellitus. The definition and diagnosis of the deprivation and poverty in diabetes type 2 based on four components of this life status: social, economic, psychological and educational is very practical for counteraction plans. Each component may have individual expression and may require a separate counteractive plan, both clinical and administrative.

Medical parameters, percentage in both groups	Deprivation/ Poverty present	Deprivation/ Poverty not present	p<0.05
Level of HbA1c			
X (SD)	10.6 (2.8)	8.2 (1.6)	*
Lack of self-control practice	86	40	*
Retinopathy - all stages	52	40	*
Nephropathy - all stages	26	5	*
Ischemic diseases			
Heart	72	64	-
Brain	62	46	*
Lower extremities	54	38	*
Neuropathy	60	36	*
Existence of additional chronic disease	89	72	*
Emotional disorders, depression	40	39	-

36

Ethnic differences in the prevalence and recognition of depression in a primary care population with and without type 2 diabetes

S. Ali[1], N.A. Taub[2], M.A. Stone[2], M.J. Davies[3], T.C. Skinner[4], K. Khunti[2]; [1]Health Sciences Research Institute, Warwick Medical School, University of Warwick, Coventry, [2]Department of Health Sciences, University of Leicester, [3]Department of Cardiovascular Sciences, University of Leicester, United Kingdom, [4]Combined Universities Centre for Rural Health, The University of Western Australia, Geraldton, Australia.

Background and aims: Results from meta-analyses suggest that the prevalence of depression is higher in people with type 2 diabetes compared to those without. However a number of methodological limitations in the literature remain including the use of inadequate control groups and a failure to control for potentially confounding factors. The present study aimed to determine the prevalence of screen detected and prevalent (currently managed) depression in a multiethnic primary care population with and without type 2 diabetes in the UK. In addition the study aimed to examine ethnic differences in the prevalence of depression between South Asian (SA) and White European (WE) people with type 2 diabetes and to assess the recognition of depression in primary care.

Materials and methods: Consecutive primary care attendees were screened for depression using the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D) during routine appointments in primary care. Demographic and medical data were also extracted from participants' primary care records.

Results: Complete data were available for 860 adults with type 2 diabetes (560 SA and 300 WE) and 643 without diabetes. No significant differences in the prevalence of depressive symptoms were observed between people with and without type 2 diabetes (HADS-D≥ 8= 28% vs.29%, P>0.05; HADS-D≥11= 17% vs. 17%, P>0.05). Higher rates of probable and/ or major depression were observed in SA people with type 2 diabetes compared to WEs: 32% vs. 22%, P= 0.006 (HADS-D≥8) and 13% vs. 10%, P= 0.166 (HADS-D ≥11). Using a cut-off of ≥8 on the HADS-D, the ethnic difference also persisted when controlling for age, gender, deprivation and the presence of one or more co-morbidity or diabetes-related complication. In those scoring ≥11 on the HADS-D, rates of unrecognised depression were higher in those with diabetes compared to those without (83% vs. 70%, P=0.004), and were significantly higher in SA in comparison to WE both in those with type 2 diabetes (90% vs. 63% P=0.018) and those without (77% vs. 50%, P=0.002).

Conclusion: In contrast to previous research, the findings showed no significant difference in risk for depression in those with diabetes compared to those without, suggesting that the association between depression and diabetes may be less robust than previously acknowledged. However in people with type 2 diabetes, higher rates of depression were observed in SAs in comparison to WEs. Furthermore our results also indicate that depression is seriously under-diagnosed in people with type 2 diabetes, most acutely in SAs, suggesting a need to improve methods of identifying depression in these patients.

OP 7 The effects of insulin beyond glycaemia

37

Insulin in patients with acute myocardial infarction and diabetes - friend or foe? A report from the DIGAMI 2 study

L.G. Mellbin[1], K. Malmberg[1], A. Norhammar[1], H. Wedel[2], L. Rydén[1];
[1]Department of Cardiology, Karolinska Institutet, Stockholm, [2]Nordic School of Public Health, Göteborg, Sweden.

Background and aims: The aim of the present report, a substudy to DIGAMI 2, is to analyze long-term mortality and morbidity in relation to different glucose lowering agents in patients with myocardial infarction and type 2 diabetes.
Materials and methods: In DIGAMI 2 patients with type 2 diabetes and suspect myocardial infarction were randomised to Group1) insulin based treatment; Group 2) insulin in-hospital followed by conventional glucose control; Group 3) conventional treatment. They were treated according to the protocol for 2.1 years and in an extended part of the trial followed up to 8.3 years (median =4.1). Long-term follow-up data was available in 1145 patients, 91.3% of the original DIGAMI 2 cohort.
Results: The total mortality was 34%, (72 % cardiovascular). Cox regression analysis did not show any difference in total or cardiovascular mortality between treatment groups. The total number of fatal malignancies was 37 with the highest risk in group 1. Hazard Ratio compared with group 2:1.83 (95%CI 0.90-3.71; p=0.096) and to group 3: 3.57 (95%CI 1.22-10.39; p=0.02). Patients on insulin treatment had a higher risk of non-fatal events (OR 1.90 (95%CI 1.38- 2.6; p=<0.0001) but not increased mortality (OR 1.30, 95%CI 0.94-1.80; p=0.11). Metformin was associated with a lower mortality (HR 0.65, 95%CI 0.47-0.90) and a lower risk of death of malignancies (HR 0.25, 95%CI 0.08-0.83; figure).
Conclusion: Patients with diabetes and myocardial infarction have a very poor prognosis. The drug used for glucose control appears to have a prognostic impact. Insulin was associated with an increased risk of non-fatal cardiac events and death due to malignancies while metformin seemed to be protective.

Safety analysis of basal insulins: mitogenic potency and receptor binding

B.F. Hansen[1], C.E. Stidsen[1], T. Glendorf[2], A. Lundby[3], A.C. Hegelund[3], C. Bonnesen[1];
[1]Department of Insulin Biology, [2]Department of Protein Chemistry, [3]Department of Cell Antibody Analysis, Novo Nordisk A/S, Måløv, Denmark.

Background and aims: The receptor binding profile of exogenous insulin may provide important information regarding mitogenicity; for example, higher affinity to the insulin-like growth factor-1 receptor (IGF-1R) has been linked to increased cellular proliferation. Furthermore, sustained signalling from the receptor might also increase cellular proliferation. Preclinical analysis has demonstrated a comparable mitogenic profile between insulin detemir (IDet) and neutral protamine Hagedorn insulin. This analysis of insulin receptor (IR) and IGF-1R binding was undertaken to evaluate the mitogenic characteristics of basal insulin analogues.
Materials and methods: Three insulin analogues were compared with human insulin: IDet, insulin glargine (IGlar) and an experimental insulin, X10. Two experiments were performed: first mitogenic potency relative to human insulin was established through proliferation of two different cell lines - human mammary epithelial cells (HMEC), and L6 myoblasts modified to overexpress human insulin receptors (L6-hIR). Then, receptor binding for IDet and IGlar was measured using both cell membranes and solubilised receptors, with binding curves generated to calculate the ratio of IGF-1R binding: IR binding profile relative to human insulin. Both isoforms of insulin receptor (A and B) were used.
Results: The mitogenic potency of IDet relative to human insulin was comparatively low for both cell lines (see Table). Data for IGlar were varied, with the HMEC cell line showing a high potency, and the L6-hIR line a relatively low potency. For X10, a consistently high potency in both cell lines was observed. When the ratio of IGF-1R:IR binding was calculated for IDet, both IR isoforms, and both techniques showed a similar ratio relative to human insulin: 0.7 (IR-A) and 1.3 (IR-B) for membrane experiments and 0.4 (both IR-A and B) for solubilised receptors. For IGlar, ratios were increased relative to human insulin: 16.2 (IR-A) and 20.5 (IR- B) for membrane preparations, and 10.7 (both IR-A and B) for solubilised receptors.
Conclusion: Compared with human insulin, IDet has a lower mitogenic potency, although further parameters of molecular safety (for example, sustained signalling from the IR or IGF-1R) may also be of note when evaluating the mitogenic potential. Our data show a similar balance between IGF-1R and IR binding for IDet and human insulin without evidence of significant differences in proliferation, supported by previous studies.

Table. Mitogenic potencies of study insulins relative to human insulin

Cell line	Functional receptor	Human insulin	Insulin detemir	Insulin glargine	X10
HMEC	IGF-1 and insulin	100%	16.9%	650%	812%
L6-hIR	Insulin	100%	9.2%	49%	744%

Changes in the concentration of serum C-peptide in type 2 diabetes during long-term continuous subcutaneous insulin infusion therapy

Y.H. Noh[1], J.H. Lee[1], J.H. Park[1], S.B. Choi[2];
[1]Biochemistry, Konkuk University, Seoul, [2]Internal Medicine, Konkuk University Hospital, Chungju, Republic of Korea.

Background and aims: Type 2 diabetes is characterized with impaired beta cell function and reduced beta cell mass which deteriorate over time. To see if beta cell function can be improved in type 2 diabetic patients through long-term continuous insulin infusion (CSII) therapy, we examined changes in serum C-peptide levels during the treatment.
Materials and methods: We discontinued oral antidiabetic drugs (OADs) and applied CSII therapy to subjects with type 2 diabetes who had failed to control hyperglycaemia with OADs and/or insulin injections (number, 34 with 59% of male; age, 56.8 ± 10.8 years; duration, 9.3 ± 7.3 years; HbA1c 7.4 ± 1.8%). Blood samplings were performed yearly for 4 years at 12 hour-overnight fasting and 30 and 120 minutes after ingestion of a standard mixed meal (500 kcal; carbohydrate 52.9%, lipid 30.4%, protein 16.7%) with at least 9 hours cessation of CSII.
Results: During the 4 year-CSII treatment, the mean HbA_{1c} significantly decreased from 7.4 ± 1.8% to 5.6 ± 0.4% ($p < 0.01$, Fig.1) and the mean serum C-peptide level at 120 minutes after meal ingestion significantly increased from 5.97 ± 2.71 to 7.46 ± 2.68 ng/ml ($p < 0.05$, Fig.1). The C-peptide increment from fasting to 120 minutes after meal also increased by 1.06 ± 1.97 ng/ml after 1 year-CSII therapy, 0.79 ± 1.91 ng/ml after 2 years, 1.61 ± 2.62 ng/ml after 3 years, and 4.27 ± 2.17 ng/ml after 4 years, respectively.
Conclusion: The resolution of glucotoxicity and maintenance of euglycaemia through long-term CSII therapy may contribute to the restoration of β-cell function in terms of serum C-peptide level after meal in type 2 diabetic patients.

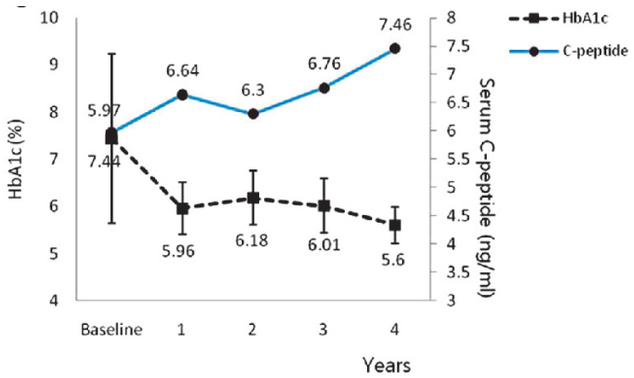

Fig.1. Changes in the mean HbA1c and the mean serum C-peptide concentration at 120 minutes after ingestion of a standard mixed meal (500 kcal) during 4 year-continuous subcutaneous insulin infusion therapy in patients with type 2 diabetes.

Body weight increase during the first year of insulin treatment in patients with type 2 diabetes mellitus; a systematic review and meta-analysis of different insulin regimens

L. Miele[1,2], A.E. Pontiroli[2], A. Morabito[2];
[1]Ospedale San Paolo, [2]Medicina, Chirurgia e Odontoiatria, Università degli studi di Milano, Italy.

Background and aims: Insulin treatment increases body weight in type 2 diabetes mellitus. Aim of this study was to define body weight increases during the first year of insulin treatment as a function of treatment modalities.
Materials and methods: We considered 51 randomized, parallel group studies with 15202 patients, lasting 12 - 52 weeks, published as full papers during years 1991 - 2009. Of each study we analyzed number of patients, duration of treatment, co-treatment with oral agents, insulin regimen (basal, bis in die, prandial), glycemic target, daily insulin doses, HbA1c and its changes, proportion of patients with hypoglycemia, body weight and its changes. Pooled-random effects of estimates of insulin regimen on body weight increase, compared with other regimens, were calculated using the Der Simonian and Laird models.
Results: Body weight increased 2.1±0.16 kg (range -0.85 - +7.5 kg, 95% C.I. 1.812-2.468), with no influence of basal body weight, lower with basal than with bis in die regimen (OR 0.42, 95% C.I. 0.25-0.59), and with no difference basal vs prandial, nor bis in die vs prandial regimen. Body weight increase was directly related (weighted regressions) to duration of treatment (r = .514,p = 0.0001), insulin dose (r = .313, p = 0.0012), HbA1c (r = .331, p = 0.0005), HbA1c change (r = .402, p = 0.0001), glycemic target (r = .203, p = 0.0462), hypoglycemia (r = .453, p = 0.0001), and nocturnal hypoglycemia (r = .281, p = 0.0434). At stepwise regression analysis (model 1: r = .783, F = 36.865; model 2: r = .735, F = 41.597), independent variables duration of treatment, HbA1c (or HbA1c change), and frequency of hypoglycemia, were significantly correlated to body weight increase (dependent variable).
Conclusion: These data indicate a slight and progressive increase of body weight in patients with type 2 diabetes during the first year of insulin treatment, related to insulin regimen, basal HbA1c, its changes, and to frequency of hypoglycemia.

41

Effects of insulin detemir and NPH insulin on renal handling of sodium, fluid retention and weight in type 2 diabetic patients

K.V. Hendriksen[1], T.J. Jensen[2], B. Feldt-Rasmussen[3], P. Oturai[4];
[1]Endocrinology and Nephrology, [2]Endocrinology, [3]Nephrology, [4]Clinical Physiology, Rigshospitalet, Copenhagen, Denmark.

Background and aim: In insulin treated type 2 diabetic patients, insulin Detemir (DET) seems to induce less weight gain compared to NPH insulin (NPH). The mechanism behind this weight-reducing effect of DET is unknown, but it has been proposed that the cause is reduced fat accumulation or reduced sodium/water retention. Due to the albumin binding and reduced glomerular filtration, and thereby reduced tubular action of DET, we tested the hypothesis that type 2 diabetic patients should increase their urinary sodium excretion (UNaE) and thereby reduce extracellular volume (ECV) and body weight (weight) when insulin treatment was changed from NPH to DET.
Material and methods: In a randomised, open-labelled, two-way cross-over study, 24 patients with type 2 diabetes and normal urinary albumin excretion (mean age: 62 yr, mean diabetes duration: 15 yr, gender 17/7 (M/F), mean HbA1c: 7.6%) were included. They were first treated with either NPH or DET for 8 weeks. In the second period, they were changed to the other insulin for 8 weeks. In a third 1-week period, they were changed back to the first insulin. At the end of each 8-week period ECV, weight and body composition (DEXA scan) was measured. In the last week of each 8 week period and on day 1, 3, and 5 in the first week after therapy change UNaE was determined. Weight was measured after 1 week. Twenty-four hour blood pressure was measured 6 times in the course of the study.
Results: At the end of 8 weeks weight was reduced by 0.8(±0.2 kg)(mean±SEM) after DET treatment compared with NPH (paired t-test: p<0.01) A non significant reduction in ECV of 0.8(±0.5 L/1.73m²)(paired t-test: p= 0.14) was found. The weight loss occurred already after 1 week 0.8(±0.2kg)(paired t-test: p<0.001) and simultaneously a transient increase in UNaE was observed (Kruskal-Wallis test: p=0.07). HbA1c increased by 0.6%(±0.1) after 8 weeks of treatment with DET (paired t-test: p<0.001) in spite of a slightly increased insulin dose, but average blood glucose measured during the first week was similar during the two treatments. In addition, 24 h blood pressure and body composition remained similar during the two treatment periods.
Conclusion: DET induces a significant and sustained weight loss, first observed within the first week after changing therapy from NPH. It was simultaneous with a trend towards a transient increase in UNaE and a reduction in ECV. The weight loss thus seems to be related to changes in fluid volume and may reflect changed insulin action in the kidneys.

Basal insulin therapy improves indexes of endothelial damage and regeneration in type 2 diabetes. A randomised cross-over trial comparing detemir vs glargine

G. Fadini, S.V. de Kreutzenberg, V. Mariano, E. Boscaro, M.C. Marescotti, C. Agostini, A. Tiengo, A. Avogaro;
Department of Clinical and Experimental Medicine, University of Padova, Italy.

Background and aims: Endothelial damage is the leading mechanism of diabetic macroangiopathy. In diabetes, endothelial regeneration is also impaired owing to reduced levels of endothelial progenitor cells (EPCs). We tested the hypothesis that therapy with basal insulin analogues influences endothelial damage and regeneration in type 2 diabetes. Since the two basal analogues have different pharmacological properties, detemir and glargine were directly compared.
Materials and methods: This was a 3-month randomized cross-over trial comparing insulin detemir once daily versus glargine once daily added to oral agents in poorly controlled (HbA1c>7.0%) type 2 diabetic patients with cardiovascular disease (ClinicalTrial.gov NCT00699686). Insulin titration was aimed at achieving fasting plasma glucose between 5.0 mmol/l (90

mg/dL) and 6.1 mmol/l (110 mg/dL) as soon as possible after enrollment. At baseline, at cross-over (3 months) and at study end (6 months), we measured HbA1c, EPC levels (as an indicator of endothelial regenerative capacity) and serum concentrations of VCAM-1, ICAM-1 and E-selectin (as indicators of endothelial damage). EPCs were defined as CD34+KDR+ or CD133+KDR+ or CD34+CD133+KDR+ cells and measured by flow cytometry. We also recorded body weight and hypoglycemic episodes.
Results: Forty-two patients completed the study: 21 followed the glargine-detemir (GD) schedule and 21 the detemir-glargine (DG) schedule. Patients were on average 66.1±1.2 year old and 74% were males. Baseline data did not differ between the two groups in terms of demographic and anthropometric parameters, HbA1c, complications and concomitant treatment. At cross-over, patients in the GD schedule had a lower HbA1c as compared to patients in the DG schedule (p=0.040). Even if this difference in HbA1c was lost at study end, the overall HbA1c effect was in favor of glargine (p=0.016). Incidence of hypoglycemia (mild and severe together) and weight gain were lower during detemir than during glargine therapy. ICAM-1, VCAM-1 and E-selectine were all significantly reduced at crossover as compared to baseline and further decreased at study end, irrespectively of the treatment schedule. At cross-over, the levels of all EPC phenotypes did not change as compared to baseline, while CD133+KDR+ and CD34+CD133+KDR+ cells significantly increased (by 68% and 139%, respectively) at study end in both groups.
Conclusion: Basal insulin therapy improves indexes of endothelial damage and regeneration in type 2 diabetic patients with cardiovascular disease. Glargine and detemir do not differ in their endothelial effects, but detemir achieved a similar endothelial protection with lower weight gain and hypoglycemic episodes, albeit at the expenses of a slightly higher HbA1c. These results might have implications for therapy of aging type 2 diabetic patients with cardiovascular disease.

OP 8 Continuous glucose monitoring - a promise of improvement?

43

Glucose control in adults during a 1-year randomised controlled trial comparing sensor-augmented pump therapy and multiple daily injection therapy: STAR 3 study

J.B. Green[1], A. Ahmann[2], R.M. Bergenstal[3], G. Dailey[4], R. Tanenberg[5], J.B. Buse[6], for the STAR 3 Study Group;
[1]Division of Endocrinology, Metabolism, and Nutrition, Duke University Medical Center, Durham, [2]Oregon Health and Science University, Portland, [3]International Diabetes Center at Park Nicollet, Minneapolis, [4]Scripps Institute, La Jolla, [5]East Carolina University, Brody School of Medicine, Greenville, [6]University of North Carolina School of Medicine, Chapel Hill, USA.

Background and aims: Recent studies have demonstrated overall improvement in glucose control with use of CGM. Sensor augmented pump (SAP) therapy combines an insulin pump with real-time integrated continuous glucose monitoring. We hypothesized SAP would improve glucose control (A1C and AUC >180 mg/dL) without increasing hypoglycemia.
Materials and methods: STAR 3 is a 1-year multicenter randomized controlled trial which compared SAP therapy using insulin aspart to multiple daily injection (MDI) therapy using insulin glargine and insulin aspart in 329 adult (age 19-70 years) and 156 pediatric (age 7-18 years) subjects with type 1 diabetes. All subjects wore a "blinded" sensor for 6 days at baseline, and the MDI subjects wore subsequent blinded sensors for 6 days at 6 months and one year. Preliminary results for the adult cohort (age 19-70 years) are given for: A1C, mean sensor glucose, area under the curve (AUC), and severe hypoglycemia.
Results: The primary endpoint of change in A1C from baseline to 1 year showed the decline in mean A1C levels was significantly greater in the SAP group compared to MDI group (SAP: from 8.3±0.5% to 7.3±0.7%; MDI: from 8.3±0.5% to 7.9±0.9%; treatment difference -0.6%; 95% CI, -0.77 to -0.45; p<0.001). The Table demonstrates that mean sensor glucose was statistically similar at baseline but significantly lower in the SAP group compared to the MDI group at 6 months (p<0.01) and 1 year (p<0.01). The improvement in glycemia with SAP was not associated with an increase in severe hypoglycemia (p=0.58) or AUC <70 mg/dL at 1 year (p=0.82). There were no between group differences in incidence of DKA (p=0.38) or weight gain (p=0.20). A greater proportion of adult subjects in the SAP group (57/166, 34.3%) reached ADA targets for A1C compared to the MDI group (19/163, 11.7%; p<0.001). AUC for sensor glucose values >180 mg/dL at 6 months and 1 year were significantly reduced in the SAP group compared to the MDI group (p<0.001).
Conclusion: SAP achieved a greater reduction in A1C and AUC>180 compared to the MDI group without an increase in hypoglycemia over a period of a year.

Table. Mean Sensor Glucose, Hyperglycemia, and Hypoglycemia, SAP and MDI Treatment Groups

	Baseline		6 Months		1 Year	
	SAP	MDI	SAP	MDI	SAP	MDI
Mean sensor glucose (SD), mg/dL	179.9 (28.9)	178.7 (27.6)	157.5* (25.4)	171.1 (31.5)	158.6* (25.7)	174.2 (31.7)
AUC>180 (SD)	28.9 (17.8)	28.0 (17.3)	16.0* (12.6)	24.7 (18.5)	16.1* (12.8)	26.0 (19.5)
ΔAUC>180	NA	NA	-12.9	-3.3	-12.8	-2.0

Effects of continuous glucose monitoring on glycaemic control in subjects with type 1 diabetes delivering insulin via pump or multiple daily injections: a prospective study

P.A. Gottlieb, L.B. Crew, E.G. Moser, M.K. Voelmle, C.R. Beatson, R.S. Gutin, S.K. Garg;
Barbara Davis Center, University of Colorado Denver, Aurora, USA.

Background and aims: There are no long-term prospective data describing the differential effects (if any) of continuous glucose monitoring (CGM) when used by patients with type 1 diabetes (T1D) who deliver insulin via multiple daily injections (MDI) as compared to those on continuous subcutaneous insulin infusion (CSII) pump therapy. This study assesses the long term effectiveness of CGM (DexCom SEVEN*PLUS) in subjects with T1D and compares the changes in glycemic control by CSII vs. MDI cohorts.
Materials and methods: Sixty adults with T1D were enrolled in this 6-month study; 30 subjects were on CSII, and 30 delivered insulin via MDI. For the first 4 weeks, all subjects were blinded from CGM values/trends/alarms; thereafter all subjects were unblinded for the remaining 20 weeks (real-time CGM data provided). A1C was measured during screening and at 4-week intervals throughout the study. Per the results of the JDRF CGM trials and the pre-specified analysis, population for this study included subjects who utilized CGM at least 6 days per week (86% of the time).
Results: Mean (±SD) age was 36 (±11) and 39 (±8) years; duration of diabetes was 22 (±11) and 23 (±10) years; and screening A1C was 7.61% (±0.76) and 7.63% (±0.68) for CSII and MDI groups, respectively (p>0.05). Seventeen patients (57%) in each group utilized CGM for at least 6 days each week. Both groups similarly improved A1C values (Figure 1a) and time spent in target range glycemia (Figure 1b). Both groups reduced time spent in hypoglycemia (180 mg/dL) was reduced by one and two hours per day in the MDI and CSII groups, respectively.
Conclusion: Similar improvements in glucose control can be achieved with real-time CGM in compliant T1D patients using either CSII or MDI.

Closed-loop insulin delivery using subcutaneous infusion and glucose sensing, and equipped with a dedicated safety supervision algorithm, improves safety of glucose control in type 1 diabetes

E.M. Renard[1], A. Farret[1], J. Place[1], S. Patek[2], C. Cobelli[3], B.P. Kovatchev[2], M.D. Breton[2];
[1]Department of Endocrinology, Diabetes and Nutrition, CHU Montpellier & University of Montpellier I, France, [2]Department of Psychiatry and Neurobehavioral Sciences, University of Virginia, Charlottesville, USA, [3]Department of Information Engineering, University of Padova, Italy.

Background and aims: The reduction of blood glucose excursions outside a near-normal range is a main goal for the improvement of control of type 1 diabetes. The modulation of insulin delivery according to blood glucose levels and variations can be achieved by using closed-loop (CL) insulin delivery systems based on continuous interstitial glucose monitoring (CGM), subcutaneous insulin infusion (CSII), and control algorithms. We investigated the new concept of modular model-based safety supervision aiming the prevention of hypoglycaemia while keeping blood glucose level in a safe range.
Materials and methods: Six type 1 diabetic patients (5 M/1F), duration of diabetes 31+/- 7 years, age 43 +/- 7, A1c 7.5 +/- 0.9 %, and BMI 25 +/- 3, treated by CSII for 7.6 +/- 3.9 years, were enrolled in a trial performed at the CHU Montpellier Clinical Research Center using Navigator CGM and OmniPod insulin pump infusing lispro to compare fully-automated CL control equipped with a dedicated safety supervision algorithm to physician-supervised CSII. The trial was composed of two periods during which each insulin delivery mode was tested in a randomised order from 2 pm to 8 am the next day. The patients performed a 30-min exercise bout on a cyclo-ergometer at 50% VO2 max from 4 pm, took a 70g CHO-meal dinner at 7 pm as well as a 20g CHO-snack at 10:30 pm, and slept from 11 pm to 8 am. Reference blood glucose was measured using YSI every 30 min from 2 to 11 pm and every hour from 12 to 8 am. Primary endpoint was the number of hypoglycaemic events according to symptoms and YSI glucose value below 70 mg/dl. Secondary study endpoints included % time spent outside a safe glucose range of 70-180 mg/dl, mean blood glucose level and maximal blood glucose difference during the entire trial periods and during exercise and following 2.5 hours, 2 hour-post dinner period, and night-time from 9pm to 8 am.
Results: Compared to CSII, CL control reduced the incidence of hypoglycaemia two-fold: from 13 to 6 events. While mean blood glucose levels (mg/dl) were similar for both periods: 155 +/- 14 (CSII) vs. 145 +/- 14 (CL), percent time spent < 70 mg/dl and > 180 mg/dl were both lower during CL vs. CSII: 2.4 +/- 0.9 vs. 4.7 +/-1.2 and 18.0 +/- 6.5 vs. 30.1 +/- 5.7, respectively. Maximal blood glucose difference (mg/dl) was significantly tighter at exercise and recovery time during CL: 84 +/- 16 vs. 123 +/- 21 (p=0.046).
Conclusion: Our preliminary data based on the first 6 patients enrolled in this pilot study show that a modular model-based safety supervision system results in fewer hypoglycaemic events and reduces the duration of blood glucose excursions outside the target range 70-180 mg/dl, as well as the amplitude of glucose variations associated with exercise in type 1 diabetes. Upcoming larger clinical trials will confirm the benefits of added safety provided by this algorithm.

Overnight closed-loop glucose control following consumption of alcohol in adults with type 1 diabetes

K. Kumareswaran[1], J. Harris[1], D. Elleri[1], J.M. Allen[1], M. Nodale[1], M.E. Wilinska[1], D.B. Dunger[1], S.A. Amiel[2], S.R. Heller[3], M.L. Evans[1], R. Hovorka[1];
[1]Institute of Metabolic Science, University of Cambridge, [2]King's College London, [3]University of Sheffield, United Kingdom.

Background and aims: Modern management of insulin in type 1 diabetes (T1D) uses flexible insulin therapy to minimise restrictions on daily life. By reducing the capacity for hepatic gluconeogenesis, alcohol consumption increases the risk of delayed hypoglycaemia. Even for those patients who reduce overnight insulin after drinking, hypo- or hyperglycaemia can follow, especially where alcohol is consumed with larger meals in social settings. We have tested a closed-loop (CL) or artificial pancreas system linking off-the-shelf

continuous glucose monitoring (CGM) and continuous subcutaneous insulin infusion (CSII) using a purpose-built model predictive control (MPC) algorithm. We recently demonstrated that overnight CL in adults significantly increased time spent in euglycaemia and reduced time in hypoglycaemia. We have now examined the efficacy and safety of CL compared with standard CSII on overnight glycaemic control, after evening alcohol intake accompanying a large dinner.

Materials and methods: Twelve adults with T1D treated by CSII (F 7, age 37.2±9.9yrs, BMI 26.8±4.2 kg/m^2, T1D duration 19.7±9.7yrs, duration on pump 1.9±2.5yrs, HbA1c 7.8±0.7%; mean±SD) were studied on 2 separate nights in random order, receiving either overnight CL (used from 2200 until 1200 the next day) or usual CSII therapy (using a similar Deltec Cozmo insulin pump on both nights). On CL nights, subcutaneous CGM values from the Freestyle Navigator were fed into an MPC algorithm every 15min, which calculated the infusion rate of Aspart (adjusted manually). On CSII nights, subjects used the Cozmo pump to deliver their usual insulin rates. On both occasions, between 2030 and 2200, a mixed meal (100g-carbohydrate) was ingested accompanied by 0.75g/kg ethanol as 13% white wine (mean volume consumed 564±133ml), with a pre-prandial insulin bolus using the subject's usual bolus calculator. Plasma glucose was measured every 15min to assess CL performance.

Results: As shown in the table, CL significantly increased the time spent in target glucose range and reduced glucose variability (plasma glucose SD). CL reduced the high blood glucose index, a composite measure of duration and severity of hyperglycaemia. One episode of severe hypoglycaemia occurred with CSII and none during CL. Notably, improved glycaemic control with CL was achieved without a difference in the average insulin dose infused.

Conclusion: CL can provide significantly better overnight glucose control than conventional CSII after alcohol and large meal consumption. CL has the potential to improve efficacy and safety of flexible insulin regimens.

Comparison of overnight plasma glucose control during CL and CSII

	CL	CSII	P
Time in target 3.9-8.0mmol/l (% of total time)	**72±15**	50±23	**0.002**
Time > 8.0mmol/l (% of total time)	23±16	37±26	**0.042**
Time < 3.9mmol/l (% of total time)	5±7	13±13	NS
Mean overnight glucose (mmol/l)	6.8±0.8	7.0±1.5	NS
SD overnight glucose (mmol/l)	1.8±0.5	2.3±0.7	**0.031**
High blood glucose index	1.8±1.6	3.2±2.6	**0.016**
Low blood glucose index	1.4±1.2	2.9±2.6	NS
Mean overnight insulin infusion (U/h)	0.9±0.4	0.9±0.4	NS

Comparison of total annual direct costs among Swedish residents with poorly controlled type 1 diabetes: standard care versus real-time continuous glucose monitoring

C. Graham[1], D.-C. Agardh[2], P. Gerhardsson[1], C.S. Hankin[3];
[1]DexCom, Inc., San Diego, USA, [2]Lund University, Malmö, Sweden, [3]BioMedEcon, Moss Beach, USA.

Background and aims: Among the 40,000 Swedish residents diagnosed with type 1 diabetes (T1DM), 18% (7,200) have poorly-controlled disease (defined as HbA_{1c} ≥9%) and are at high risk for developing diabetes-related complications. Randomized clinical trials (RCTs) have shown that real-time continuous glucose monitoring (RT-CGM) significantly improves HbA_{1c} (A1c) levels among those with T1DM. We developed a decision-tree model to compare anticipated rates and costs of diabetes-related complications among a hypothetical group of 7,200 Swedish subjects with poorly-controlled T1DM who received RT-CGM or standard therapy (ST).

Materials and methods: T1DM prevalence was obtained from the National Board of Health and Welfare and A1c levels from the Swedish Diabetes Registry; A1c improvement among those with poorly-controlled T1DM who used RT-CGM was obtained from a RCT; rates of microvascular complications in Swedish subjects with T1DM were derived from the Stockholm Diabetes Intervention Study and the Diabetes Complications and Control Trial. Rates of severe hypoglycemia in T1DM were based on observational studies of Swedes and a RCT of RT-CGM. Annual direct medical costs of were obtained from published Swiss (serious retinopathy) and Swedish (nephropathy, peripheral neuropathy, severe hypoglycemia) economic analyses and reported as 2009 USD. Costs for 7-day, continuous, RT-CGM were provided by a manufacturer of RT-CGM devices.

Results: Among the 7,200 who received RT-CGM, 26% achieved a 2-point A1c reduction, 50% a 1-point reduction, and 24% no improvement at 1 year; among a comparable group of 7,200 Swedish subjects who received ST, A1c did not change from baseline. Among those who received RT-CGM versus ST, 3,949 and 5,832, respectively, experienced microvascular complications, and 720 and 1,440-2,520, respectively, severe hypoglycemia. The total annual reduced direct costs associated with diabetes-related complications for those who received RT-CGM versus ST ranged from $43.3 to $45.9 million. The cost of receiving RT-CGM was $43.5 million ($6,038 per person). Thus, RT-CGM reduced 2,603-3,683 diabetes-related complications over 1 year ranging from a net break-even to a cost savings of $2.4 million.

Conclusion: In this decision-tree model, use of RT-CGM by 7,200 Swedes resulted in 2,603-3,683 (36-44%) fewer diabetes-related complications per year compared with ST at an estimated reduction in the direct cost of diabetes-related complications ranging from $43.3 to $45.9 million. The model demonstrates that this technology is a cost-effective means of reducing diabetes-related complications among Swedish persons with poorly-controlled T1DM. Because not all direct costs for diabetes-related complications (e.g., macrovascular events) were included in the model, RT-CGM may be associated with even greater cost savings relative to ST.

Accuracy of a continuous glucose monitoring system (CGMS): still room for improvement

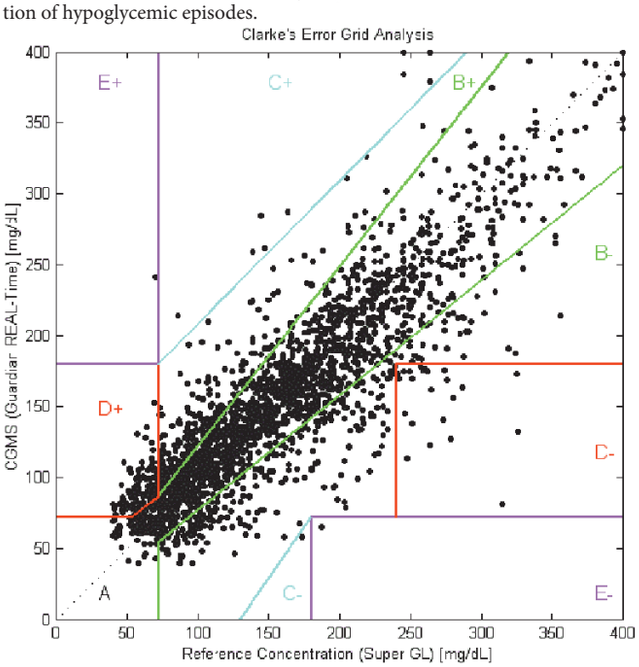
S. Heckermann, L. Nosek, E. Zijlstra, T. Heise;
Profil Institut fuer Stoffwechselforschung GmbH, Neuss, Germany.

Background and aims: Clinical trials have shown improvements in glycemic control through CGMS in people with type 1 diabetes (T1D), but systematic investigations of the accuracy of CGMS are scarce. We studied the performance of the Guardian Real Time CGMS in 17 T1D (6 females, mean age 43 (26-61) years, HbA1c 8.3 (7.6-8.9)%, all on basal-bolus insulin therapy).

Materials and methods: During two in-house stays of 7 days each with standard meals (identical for both periods) patients were connected to CGMS (hypoalarm setting 70 mg/dl with a predictive alarm 10 min earlier). Reference measurements using a laboratory device (Super GL glucose analyzer, Hitado, Möhnesee, Germany) were done at least every 4 hours and in case of hypoglycemic symptoms or a CGMS hypoalarm. All reference measurements were used for CGMS calibration.

Results: In total, 2328 paired data points were obtained covering a glucose range of 40 - 400 mg/dl. Mean absolute deviation was 24.5±24.0 mg/dl, mean relative absolute deviation was 18.3±18.7%. Frequent calibration did not seem to improve accuracy, relative absolute deviations for values obtained within 1h after calibration was 18.8±18,6%. A Clarke Error Grid analysis showed 93% of paired values to be in zones A (67.4%) and B (25.6%), but also 6.4% in zone D (figure). Reference measurements indicated 145 episodes of hypogly-

cemia (blood glucose (BG) < 70 mg/dl) of which only 43 were detected with CGMS. Sixty additional CGMS hypoglycemic alarms were not confirmed, i.e. reference measurements showed BG values > 90 mg/dl. Thus, while CGMS had high specificity (97%) and good negative predictive value (95%) for hypoglycemia, positive predictive value (42%) and sensitivity (30%) were poor.
Conclusion: In conclusion, further improvements in the accuracy of CGMS measurements seem to be necessary in particular for a more reliable detection of hypoglycemic episodes.



OP 9 GWAS and their follow-up: analytical, technological and experimental developments

Genome-wide association analysis in over 187,000 individuals identifies 14 loci contributing to variation in fat-distribution
C.M. Lindgren, on behalf of the GIANT (Genetic Investigation of ANthropmetric Traits) Consortium.; Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom.

Background and aims: Obesity is an increasing public health issue, but not all forms of obesity carry the same risk. Individuals with high waist-to-hip ratio (WHR) have an increased risk of Type 2 Diabetes (T2D), hypertension, heart disease, stroke and certain cancers. WHR is one of the primary measures of fat distribution and has a substantial heritability (~50%), independent of overall adiposity. Hitherto, the genetic variants that contribute to variation in WHR have not been well characterized.
Materials and methods: To detect common variants, we performed a meta-analysis of 32 genome-wide association studies comprising >77,000 individuals of European ancestry as part of the GIANT consortium. We tested ~2.8 million imputed and genotyped SNPs for association with WHR using an additive model, adjusted for age and BMI and sex.
Results: Our discovery analysis identified 16 independent loci associated with WHR with >110,000 individuals). In our analysis combining discovery and follow-up studies 14 loci reached genome-wide significance (p<5x10-8). We confirmed the known locus near LYPLAL1 (1q41; p=4.9x10-19) and identified 13 novel associations, including four loci that suggest an overlap with developmental processes and T2D risk: RSPO3 (6q22; p=1.8x10-40), near VEGFA (6p12; p=5.9x10-25), TBX15 (1p11; p=8.7x10-25), and near ADAMTS9 (3p14; p=9.8x10-14). RSPO3 may regulate embryonic angiogenesis via the Wnt signaling pathway. TBX15 is differentially expressed between subcutaneous and visceral fat and the expression is correlated with WHR. VEGFA is a growth factor that has been suggested to play a role in diabetic nephropathy and retinopathy. ADAMTS9 is significantly associated with T2D, possibly mediating an effect through decreased insulin sensitivity of peripheral tissues. We find a directionally consistent enrichment of associations (above what would be expected by chance) for each single trait (P nominal <0.05) with increased triglycerides, LDL-cholesterol, fasting insulin, and HOMA-IR. We also observed a marked gender difference in our results; 7 of the 14 loci showed a stronger association in women than in men.
Conclusion: Taken together, these results promise to enhance our knowledge of underlying biological pathways involved in fat-distribution and propose a genetic overlap with metabolic risk and T2D. Hopefully these advancements will support functional and translational advances in the management of obesity through development of novel diagnostic and therapeutic options.

Genetic susceptibility for obesity increases the risk of type 2 diabetes and is modified by macronutrient intakes
G. Rukh, E. Sonestedt, V. Lyssenko, A. Sharma, O. Melander, M. Orho-Melander;
Clinical Sciences in Malmö, Lund University, Malmoe, Sweden.

Background and aims: Genome-wide association studies (GWAS) have identified at least 16 novel single nucleotide polymorphisms (SNPs) associated with BMI or obesity. The aims of this study were to examine whether these SNPs associate with obesity, type 2 diabetes or cardiovascular disease (CVD) in Swedish population and to investigate if dietary intake (relative intakes of fat, carbohydrate, protein and fiber) or physical activity level modify the genetic effect, measured as a genetic risk score (GRS), on BMI and body composition.
Materials and methods: In total 17037 individuals from the Malmö Preventive Project (MPP) were genotyped and a weighted GRS was created. Association between SNPs and GRS and BMI, obesity, type 2 diabetes and CVD were studied cross-sectionally and prospectively after a mean of 23 years follow-up. A total of 9023 non-diabetic subjects participated in the population-based Malmö Diet and Cancer Study (MDCS) with dietary data from a modified diet history method and with leisure time physical activity determined and

were included to GRS x diet interaction analyses. Bioelectric impedance analysis was used to estimate body composition.
Results: 14 SNPs associated with BMI or related traits and were included in GRS. A 13% (10-17%) increased risk of obesity for each increased quintile of GRS was observed ($p=3x10^{-16}$). Individuals in the highest vs. lowest GRS had a 29% (14-46%) increased risk of type 2 diabetes ($P= 5x10^{-5}$ and P=0.006 after adjustment for BMI). GRS was not significantly associated with CVD (p=0.12). The effect sizes of GRS quintiles on BMI were 2.2, 1.9 and 1.7 times higher comparing low carbohydrate-, low fiber and high fat intake tertiles to high carbohydrate, high fiber and low fat intake tertiles (p=0.016, p=0.022 and p=0.084 for interaction, respectively). Interactions were strongest on lean mass (p=0.002, p=0.001 and p=0.049). Effect sizes of GRS on BMI, fat mass or lean mass did not significantly differ between tertiles of leisure time physical activity (p=0.44, p=0.88 and p=0.26, respectively).
Conclusion: GRS of 14 BMI/obesity SNPs associates with obesity and type 2 diabetes. Diets low in carbohydrates and fiber and/or high in fat may accentuate genetic susceptibility for obesity, particularly accumulation of fat-free mass in males. The fairly modest combined effect size on BMI by the so far identified BMI/obesity SNPs can partially be explained by the effect sizes being modified by dietary intakes.

A genome-wide association analysis of over 75,000 individuals identifies gender-specific effects for fasting glycaemic traits
R. Mägi[1], J.J. Hottenga[2], I. Prokopenko[1,3], MAGIC Investigators;
[1]WTCHG, University of Oxford, United Kingdom, [2]Department of Biological Psychology, VU University Amsterdam, Netherlands, [3]OCDEM, University of Oxford, United Kingdom.

Background and aims: Meta-analyses of genome-wide association (GWA) studies for glycaemic traits up to date have described 16 loci influencing fasting glucose (FG) and two loci - fasting insulin (FI) levels. FG levels are tightly regulated, but may differ between genders. Gender differences in prevalence of IFG (impaired fasting glucose) and IGT (impaired glucose tolerance) are well known: IFG is more common in men and IGT in women but the mechanisms for these differences are unknown. Within the Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC) we aimed to investigate gender-specific differences in genetic regulation of FG/FI levels, since such effort in a large enough sample was lacking.
Materials and methods: To identify gender-specific genetic effects we performed gender-stratified meta-analyses of 36 genome-wide association (GWA) studies informative for FG and FI within MAGIC in up to 32,993 and 27,870 non-diabetic men and 42,149 and 34,940 non-diabetic women, respectively. Age information was provided for ~69,600 individuals from 32 cohorts. Mean age in males was 53.5(SD=10.2) and in females was 51.1(SD=10.8) years.
Results: Among previously described loci *DGKB-TMEM195I* demonstrated the largest differential effect estimates (heterogeneity Q P=0.026, I^2=80%) stronger in men (β=0.031 [SE=0.004], $P=9.1x10^{-14}$) than in women (β=0.019 [SE=0.004], $P=1.1x10^{-7}$). Gender-specific heterogeneity for *MTNR1B* was also high (Q $P<0.05$, I^2=75%) with higher effect estimates for men (β=0.080 [SE=0.005], $P=3.7x10^{-56}$) than for women (β=0.067 [SE=0.004], $P=3.3x10^{-51}$). Effects estimates in women were higher for *C2CD4B* and *GCKR*, where the gender heterogeneity was close to high, but not significant (I^2~60%, Q $P>0.05$). *G6PC2* and *ADCY5* showed moderate and *GCK, PROX1, SLC30A8* low between-gender heterogeneity for FG ($I^2 \leq 50\%$ and $I^2<25\%$, respectively). We couldn't detect gender-specific differences in the FG effect estimates for *MADD, FADS1, CRY2, ADRA2A, GLIS3*, *SLC2A2 TCF7L2* and at *GCKR* for FI (heterogeneity I^2=0%). In FG meta-analysis we uncovered a novel locus showing strong heterogeneity (Q P=0.055, I^2=73%) near *PCSK1* with women showing β=0.023 [SE=0.003], ($P=3.0x10^{-9}$) and men β=0.012 [SE=0.004], (P=0.008); overall β=0.018 [SE=0.003], ($P=9.0x10^{-10}$). Meta-analysis of FI has revealed higher effect estimates in men (β=0.034 [SE=0.006], $P=3.3x10^{-8}$) compared to women (β=0.018 [SE=0.006], P=0.001) at rs860598 (overall β=0.024 [SE=0.004], $P=3.6x10^{-9}$, heterogeneity Q P=0.042, I^2=76%) in *IGF1* locus, showing a stronger association than the previously described variant rs35767 (overall $P=4.7x10^{-8}$, linkage disequilibrium r^2=0.77).
Conclusion: We showed that some genetic loci have greater contribution to the fasting glycaemic traits variability in men (*DGKB, MTNR1B, IGF1*) than in women and vice versa (*PCSK1*) owing to differential gender-specific physiological mechanisms of regulation of glycaemic traits. We also unveiled a novel FG locus near *PCSK1*. This analysis showed the importance of deep investigation of between-gender differences for quantitative phenotypes related to type 2 diabetes. Well powered GWA analyses should investigate the gender contribution to the quantitative traits variability in a systematic manner.

Identification of additional type 2 diabetes susceptibility loci through large-scale replication using "Metabochip": early result
I. Prokopenko[1,2], A. Mahajan[3], V. Lagou[1,2], N. Robertson[1,2], W. Rayner[1,2], A. Kumar[1], C.J. Groves[2], D. Buck[1], A. Doney[4], C.N.A. Palmer[5], A.D. Morris[5], A.P. Morris[1], C.M. Lindgren[1,2], M.I. McCarthy[1,2], for the DIAGRAM consortium;
[1]WTCHG, University of Oxford, [2]OCDEM, University of Oxford, United Kingdom, [3]Institute of Genomics and Integrative Biology, CSIR, Delhi, India, [4]Department of Medicine & Therapeutics, Ninewells Hospital & Medical School, Dundee, United Kingdom, [5]Biomedical Research Institute, University of Dundee, Ninewells Hospital & Medical School, Dundee, United Kingdom.

Background and aims: Over 30 common variant signals influencing type 2 diabetes (T2D)-susceptibility have been identified so far. However, replication efforts to date have focused on limited numbers of the most strongly-associated signals and have failed to exploit fully the information provided by the well-powered genome wide association (GWA) meta-analyses available for stage 1 discovery. The Metabochip - a custom iSELECT array containing ~195,000 SNPs - has been designed to support large-scale follow-up of putative associations for T2D and other metabolic and cardiovascular traits, and to enable the fine-mapping of known loci.
Materials and methods: This analysis is based on Metabochip data from 3,185 T2D cases and 3,569 controls (from the UK T2D Genetics Consortium sample recruited in Tayside, Scotland) that were successfully called (Gencall v1.1) and passed quality control (QC). Of 185,802 Metabochip SNPs passing QC, 4,821 were included in this analysis because they capture the top ~5,000 independent autosomal signals from the DIAGRAM (v3) GWA meta-analysis (12,057 T2D cases, 56,071 controls, all of European-descent). Association analysis was performed under an additive model with adjustment for 3 principal components to account for sample substructure.
Results: We observed directional consistency for all published T2D-loci (and for 11 novel autosomal loci derived from the most recent DIAGRAM+ consortium effort) including variants at *TCF7L2* ($P<10^{-14}$); *SLC30A8*, *KCNQ1*, *FTO* ($P<10^{-4}$); *KCNJ11* and *IRS1* ($P<5x10^{-3}$). We compared overall patterns of replication between the DIAGRAM stage 1 discovery data and the UK-T2DGC follow-up results for 4,333 independent SNPs represented in both samples. Of these, 2,468 SNPs showed directionally consistent effects (binomial $p<10^{-19}$) with 217 of the 2,468 also showing nominal replication (i.e. $p<0.05$, same effect direction). Only 79 of 4,333 SNPs had $p<0.05$ in the opposite direction (binomial $p<10^{-18}$). Despite the modest size of this first follow-up sample (compared to the discovery set), joint analysis of DIAGRAM+ Stage 1 and UKT2DGC Stage 2 data revealed several signals near to or exceeding genome-significance, including a locus near *ARL15* (ADP-ribosylation factor-like 15) on chromosome 5p15 (UKT2DGC $P=10^{-4}$, meta-analysis $P=3.2\times10^{-8}$, OR=1.11[95%CI 1.07-1.16]).
Conclusion: These preliminary data obtained from the Metabochip are consistent with a long tail of common variant association signals of modest effect contributing to T2D-susceptibility. Metabochip-genotyping is currently underway in over 30,000 T2D cases and 50,000 controls of European descent. Follow-up on this scale should add considerably to the tally of proven T2D-susceptibility loci. Even in this modestly scaled initial follow-up effort, we have identified one novel T2D-susceptibility signal mapping to chromosome 5p15.

53

Fine-scale mapping of type 2 diabetes susceptibility loci by imputation and conditional analysis

S. Wiltshire[1,2], C.M. Lindgren[1], A.P. Morris[1], I. Prokopenko[1,2], M.I. McCarthy[1,2];
[1]Wellcome Trust Centre for Human Genetics, Oxford, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom.

Background and aims: Up to 30 T2D susceptibility genes have been identified in the past few years from genome-wide association scans (GWAS). In this study, we focus on three regions implicated by GWAS in European populations - CDKAL1, CDKN2A/B, and FTO. To facilitate identification of the causative variants within these genes, we have undertaken fine-scale mapping at greater marker density, and explore the possibility of multiple causative signals in each gene.
Materials and methods: We used 1924 T2D cases and 2938 controls previously studied in a 500K GWAS by the Wellcome Trust Case Control Consortium (WTCCC). We used imputation (with IMPUTEv2) to estimate the genotypes of an additional 3157 SNPs (frequency>1%) across these regions. This method uses a single, hierarchical, approach to combine a primary reference set of 112 phased CEU chromosomes from the 1000 Genomes project (August 2009 release) with a secondary panel of an additional 298 phased CEU and Tuscan chromosomes from the HapMap Phase 3 project (release 2). We analysed each SNP under an additive genetic model using SNPTEST v1.1.4. We performed conditional analyses, adjusting for the most significant SNP at each stage using a forward selection strategy.
Results: At CDKAL1 we identified a cluster of imputed SNPs (the best being rs10440833, risk-allele frequency (RAF) =0.32, allelic OR=1.28, $P=7.3x10^{-8}$), with stronger T2D association than the previously reported lead SNPs (rs9465871 and rs10946398) from the WTCCC GWAS. This cluster is focussed on a 27kb haplotype block flanked by rs9465871 and rs10946398. We found a second independent signal at imputed SNP rs6930283 (P=0.0005, RAF =0.32) 100kb 5' to the primary signal. In CDKN2A/B, the most significant signal from our imputed data was seen at rs7018475 (RAF=0.30, allelic OR=1.37, $P=1.2x10^{-9}$), at the 3' end of the 9kb haplotype block containing rs10811661, the previously reported lead SNP. Rs10811661 remains associated (with P=0.004) after accounting for rs7018475, suggesting it represents a largely independent effect. At FTO, our imputed genotypes provide further evidence for association with BMI (in T2D cases, age & sex-adjusted) across the 50Kb haplotype block implicated in the WTCCC GWAS. The best signal in our study comes from imputed SNP rs11646715 ($P=3.5x10^{-6}$). Conditioning the analysis on rs11646715 completely abolishes the evidence for association (P>0.2 at all SNPs) across the region. The strongest association with T2D from our imputed data in FTO comes from rs1421086 (allelic OR=1.27, $P=1.8x10^{-8}$), comparable with previously identified lead SNPs rs7193144, rs8050136 and rs9939609. Conditioning association analysis on imputed SNP rs1421086, or these three lead SNPs, largely ablates the evidence for T2D association across the 50Kb haplotype, with the best residual signal being imputed SNP rs1861867 (P=0.001-0.005) in each case.
Conclusion: Imputation using data from the 1000 Genomes and HapMap3 projects is a valuable tool for fine-mapping loci, identified from GWAS, with near complete coverage of common variants. Using this approach, we have more precisely localised the causative variants in CDKAL1, CDKN2A/B and FTO. These newly identified imputed variants are candidates for further genotyping and functional assessment.

Insights into glucokinase regulatory protein regulation from the cellular and kinetic characterisation of rare coding variants

M.G. Rees[1,2], C. Turner[2], F.M. Facio[2], N.L. Beer[1], NISC Comparative Sequencing Program, M.I. McCarthy[1], L.G. Biesecker[2], A.L. Gloyn[1], F.S. Collins[2];
[1]Oxford Centre for Diabetes Endocrinology & Metabolism, United Kingdom, [2]National Institutes of Health, Bethesda, USA.

Background and aims: Genes containing common variants of significant phenotypic effect may also harbour rare variants (Minor Allele Frequency [MAF] <5%) of large effect. The common P446L glucokinase regulatory protein (*GCKR*; protein name GKRP) variant is associated with decreased risk of type 2 diabetes, lower fasting glucose and insulin, and increased triglyceride levels. GKRP binds and inhibits glucokinase (GCK) in the liver, sequestering GCK in the nucleus in the fasting state. Increased glucose levels trigger GCK dissociation from GKRP, nuclear GCK export, and GCK activation. Functional analysis suggests the P446L variant acts through decreasing F6P-mediated inhibition of GCK, increasing liver glucose uptake and disposal. The aim of this study was to identify and functionally characterise rare *GCKR* variants for cellular localization and GCK inhibition to provide insight into mutation severity and direct both clinical and genetic follow-up.
Materials and methods: Exonic *GCKR* sequencing was performed in 664 individuals from the multi-ethnic NIH ClinSeq project using standard methodology**.** Nonsynonymous variants (published and novel) were introduced into a YFP-tagged GKRP expression plasmid. Wild-type (WT) and variant YFP-GKRP were transiently transfected into HeLa cells and cellular localisation assessed microscopically 24 hours post-transfection. CFP-tagged GCK was co-transfected with YFP-GKRP to assess GCK interaction and nuclear sequestration. Recombinant human GCK and both WT and Q234P GKRP were generated. Q234P-GKRP and WT-GKRP inhibition of GCK activity and regulation by F1P and F6P were determined spectrophotometrically using an NADP+ coupled assay.
Results: Twelve (nine novel) nonsynonymous variants were identified. Seven variants were observed in only one individual. Excluding P446L, variants had MAFs ranging from 0.2-1% in the ClinSeq cohort. Of novel variants, only one (Q234P) was identified in the 1000 Genomes project. WT YFP-GKRP localized primarily to the nucleus and was necessary and sufficient to sequester CFP-GCK to the nucleus. Of 18 variants tested, 12 (including P446L) had increased cytoplasmic: nuclear fluorescence compared to WT. Of the 12 variants with increased cytoplasmic fluorescence, six (including Q234P) did not sequester CFP-GCK to the nucleus. Kinetic analysis showed no difference in inhibition of GCK activity by WT- or Q234P-GKRP over a glucose concentration range of 0-100mM. However, response to 20-500μM F1P (n=38; $5x10^{-9}<p<0.02$) and 10-500μM F6P (n=41; $1x10^{-6}<p<0.02$) were both significantly diminished with Q234P-GKRP.
Conclusion: A large proportion (67%) of nonsynonymous *GCKR* variants disrupt nuclear localization and/or interaction with GCK in a cellular context. Since there is no apparent variant clustering it suggests that many changes in GKRP primary structure can affect global folding and three-dimensional structure. Prioritisation of variants for additional genetic analysis and targeted phenotyping may be aided not only by determining the MAF in appropriate ethnic groups but also by selecting variants such as Q234P that show both altered GCK sequestration and kinetic parameters.

Exercise-induced reduction in liver fat is accompanied by improvements in vascular function in non-alcoholic fatty liver disease

C.J. Pugh[1], H. Jones[1], V.S. Sprung[1], G.J. Kemp[2], A. Irwin[3], V.L. Adams[2], W.E. Bimson[2], N.T. Cable[1], D.J. Green[1], P. Richardson[4], D.J. Cuthbertson[3]; [1]Research Institute for Sport and Exercise Science, Liverpool John Moores University, [2]Magnetic Resonance and Image Analysis Research Centre (MARIARC), University of Liverpool, [3]Department of Diabetes and Endocrinology, University Hospital Aintree, Liverpool, [4]Departement of Haemotology, Royal Liverpool University Hospital, United Kingdom.

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD), the hepatic manifestation of the metabolic syndrome is characterised by the accumulation of triglycerides in the liver and is associated with liver-related morbidity and mortality as well as increased cardiovascular risk. Exercise training is recommended as a therapeutic technique to reduce hepatic fat in NAFLD patients, yet the efficacy of exercise training remains equivocal. Flow mediated dilation (FMD), the increase in conduit artery diameter in response to increases in flow, provides information regarding endothelial cell health and is an early barometer of cardiovascular disease. Endothelial function has been shown to improve with exercise training in young healthy, older sedentary and obese individuals but has not been investigated in the NAFLD population. Therefore, the aim of this study was to examine the effect of regular exercise on intrahepatocellular lipid (IHCL) content and endothelial function in NAFLD patients.
Materials and methods: 6 sedentary NAFLD patients aged 56±9 yrs underwent a 16-week supervised exercise training program (30-45mins, 3-5 times per week). Whole body magnetic resonance imaging with proton magnetic resonance spectroscopy was used to determine IHCL levels prior to and following training (n=5). Fasting glucose, lipids, AST and ALT, brachial artery FMD, responses to glyceryl trinitrate (GTN) and cardiorespiratory fitness (VO_{2peak}) were also assessed before and after training. Differences between baseline and post-training data were analysed using paired t-tests. Data are described as mean±SD.
Results: IHCL significantly reduced by 28.7% following exercise training compared to baseline (21.4±13.7 vs 17.2±13.8%; P=0.01), this was accompanied by a significant improvement in FMD (7.3±3.8% vs 3.8±1.6%, P=0.02). Liver enzymes also significantly improved following exercise training; ALT was reduced to 28±6U/l from 39±9U/l at baseline (P=0.008). Fitness improved by 20.2% (23.50±4.56 vs 28.52±8.82ml/min/kg; P=0.06) and body mass (79.6±10.9 vs 77.2±12.0kg; P=0.04) and AST (P=0.01) were significantly reduced following exercise training. No significant changes in GTN or lipid profiles were evident after exercise training.
Conclusion: This is the first study to demonstrate that both IHCL and endothelial function significantly improve following exercise training in NAFLD patients. This indicates that regular exercise has concomitant therapeutic effects on both excess hepatic fat and cardiovascular disease in these high risk patients. The exercise-mediated improvement in IHCL and FMD was accompanied by clinically significant reductions in liver enzymes and body mass. These data strongly support the efficacy of exercise training as a non-pharmacological management strategy in NAFLD and suggest as well as improving liver function, exercise may decrease the risk of heart disease and stroke in these patients.

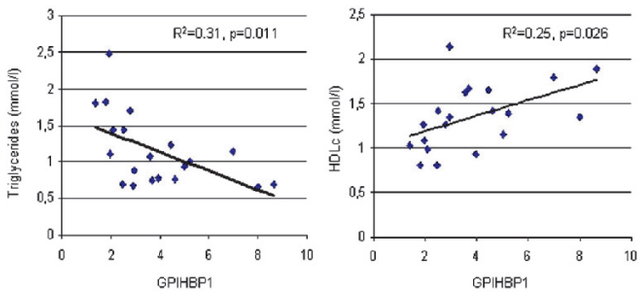
Study of GPIHBP1 expression in human adipose tissue, correlation with lipid parameters and regulation by rosiglitazone

S. Charriere[1,2], A. Tchernof[3], C. Debard[1], M. Laville[4], P. Moulin[2], H. Vidal[1]; [1]INSERM unité 870, Oullins, [2]Fédération d'endocrinologie du pôle est, Hospices Civils de Lyon, France, [3]Centre de recherche en endocrinologie moléculaire et oncologique, Québec, Canada, [4]Centre de recherche en nutrition humaine, Lyon, France.

Background and aims: Glycosyl phosphatidyl inositol HDL binding 1 (GPIHBP1) gene encodes for a new endothelial surface binding site for lipoprotein lipase (LPL), the key enzyme for intravascular lipolysis of triglyceride-rich lipoproteins. Mice lacking GPIHBP1 manifest severe hyperchylomicronemia with lipolysis defect. Similarly to LPL, GPIHBP1 is expressed in adipose tissue, skeletal muscle and heart. GPIHBP1 expression is stimulated by rosiglitazone (PPARγ agonist) in mice. GPIHBP1 involvement in triglyceride (TG) metabolism is not clearly established in Humans. The aim of this study is to investigate GPIHBP1 expression levels in human adipose tissue of healthy and type 2 diabetic subjects, its correlation with lipid parameters, and its potential regulation by rosiglitazone.
Materials and methods: We studied GPIHBP1 expression by quantitative RT-PCR in sub-cutaneous adipose tissue (SCAT) and/or visceral adipose tissue (VAT) biopsies of 20 healthy subjects and of 17 type 2 diabetic subjects after 12 weeks of placebo or rosiglitazone (4 mg/day).
Results: In healthy subjects, GPIHBP1 is expressed in both SCAT and VAT, with a significant correlation between the 2 tissues (R^2=0.49, p=0.001). We find an inverse significant correlation between TG and GPIHBP1 expression in SCAT (R^2=0.31, p=0.011) (Figure) and in VAT (R^2=0.26, p=0.021). Conversely, HDLc is positively correlated with GPIHBP1 expression only in SCAT (R^2=0.25, p=0.026) (Figure) (VAT: R^2=0.11, p=0.144). Other lipid parameters, age and body mass index are not significantly associated with GPIHBP1 expression neither in SCAT or VAT. Additionally, GPIHBP1 expression is correlated with TG in type 2 diabetic subjects in SCAT (R^2 =0.41, p=0.034). Moreover, its expression is significantly increased by rosiglitazone compared to placebo (+ 32.6 %, p=0.022).
Conclusion: We show for the first time in Humans that GPIHBP1 is expressed in both SCAT and VAT and that its expression is inversely correlated with TG in healthy and type 2 diabetic subjects and regulated by a PPARγ agonist. These results suggest an important role for GPIHBP1 in TG metabolism in Humans.



Correlation between lipid parameters (TG, HDLc) and GPIHBP1 expression in SCAT

Cardiac lipid content increases upon exercise-induced elevation of plasma fatty acid concentrations

L. Bilet[1], T. van de Weijer[1], M.K.C. Hesselink[2], J. Glatz[3], H. Lamb[4], M. Schär[5], J. Wildberger[6], M.E. Kooi[6], P. Schrauwen[1], V. Schrauwen-Hinderling[1,6]; [1]Human Biology, MUMC, Maastricht, [2]Human Movement Sciences, MUMC, Maastricht, [3]Molecular Genetics, MUMC, Maastricht, [4]Radiology, Leiden University Medical Center, Maastricht, Netherlands, [5]Philips Healthcare, Cleveland, USA, [6]Radiology, MUMC, Maastricht, Netherlands.

Background and aims: Increasing evidence suggests that excessive lipid accumulation in cardiac tissue hampers cardiac function, predisposing to cardiomyopathy and heart failure. Cardiac energy status (PCr/ATP) has strong prognostic value in heart failure patients and might be an early marker of disturbed cardiac metabolism, and it has been suggested that cardiac lipid accumulation reduces the energy status. We have previously shown that elevated levels of circulating FA, induced by exercise in the fasted state, lead to increased levels of lipids in non-active skeletal muscle. However, it is unknown if the heart responds similarly. Here, we aimed to investigate if elevating plasma FA by exercise results in an increased IntraCardiomyoCellular Lipid (ICCL) content, and if this influences cardiac function and energy status.
Materials and methods: Nine male subjects (age: 25 ± 1.2 y, BMI: 23.0 ± 1.0 kg/m2) underwent proton cardiac Magnetic Resonance Spectroscopy (1H-MRS) (Intera, 1.5T, Philips Healthcare) in the morning in the fasted state to determine ICCL. Subsequently, subjects cycled for two hours at 50% of maximal performance. ICCL was measured directly after exercise and again four hours post-recovery, together with systolic function (by multi-slice cine-MRI) and cardiac energy status (by 31P-MRS). All subjects underwent this procedure twice, once while fasted, and once while ingesting glucose during both exercise and recovery (bolus: 1.4g/kg, 8 x 0.35 g/kg), which has previously been shown to prevent elevation of plasma FA levels. For cardiac 1H-MRS, a 6 cm3 VOI was placed in the septum of the heart (PRESS, TR = 4s, TE

= 26ms, n = 128). Signal acquisition was ECG-triggered to end-systole and respiratory-gated using a pencil beam navigator. Lipid content is expressed as percentage of the CH2 peak, relative to the unsuppressed water signal. For cardiac 31P-MRS, ISIS was used for localization to the left ventricle (TR = 3.6 s, n = 192).
Results: Plasma FA concentrations were increased three-fold during exercise and nine-fold during recovery in the fasted condition compared with the glucose condition ($p<0.01$). Fat oxidation was significantly higher in the fasted condition compared with the glucose-supplemented condition. ICCL was elevated at the end of the fasted test day (from 0.26 ± 0.04 to 0.44 ± 0.04 %, $p<0.01$), while it did not change when glucose supplementation was given (from 0.32 ± 0.03 % to 0.26 ± 0.05%, $p=0.3$). There were no changes in ICCL directly after acute exercise. Furthermore, PCr/ATP was decreased by 32% in the high plasma FA condition compared with the low FA condition ($n=6$, $P=0.014$). However, in the high FA condition, the ejection fraction post-recovery was higher compared with the low FA condition (63 ± 2 % vs 59 ± 2 %, $p=0.018$).
Conclusion: The increase in ICCL in the fasted condition suggests that plasma FA concentrations play an important role in determining ICCL. Furthermore, increased ICCL was associated with a decreased cardiac energy status (lower PCr/ATP), which is in line with the "lipotoxic" action of cardiac lipids. However, ICCL seems not to be the main determinant of cardiac function.

58

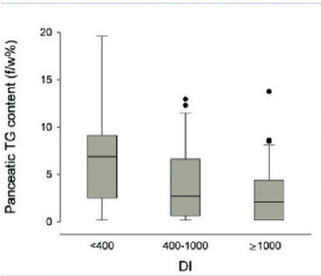
Ectopic lipid accumulation in the heart of severe obese patients: relationship to cardiac function and visceral fat
B. Gaborit[1,2], F. Kober[3], A. Jacquier[4], T. Cuisset[2], S. Boullu[1], M.-C. Alessi[2], K. Clement[5], M. Bernard[3], A. Dutour[1,2];
[1]Department of Endocrinology, Metabolic Diseases, and Nutrition, CHU Nord, Marseille, [2]Inserm U626, Marseille, [3]13005, Centre de Résonance Magnétique Biologique et Médicale (CRMBM) UMR CNRS, Marseille, [4]Centre de Résonance Magnétique Biologique et Médicale (CRMBM) UMR CNRS Marseille, [5]Institut national de la santé et de la recherche médicale, Paris, France.

Background and aims: Epicardial fat is an ectopic fat depot which development is associated with coronaropathy. Its closed anatomic situation to the adjacent myocardium allows local paracrine interaction, suggesting that EF could have a functional role in obesity related cardiomyopathy. Myocardial lipid deposition is also a marker of ectopic fat accumulation, that could lead to impaired myocardial function, as suggested by preliminary results limited to midly obese patients. In this study, we quantified with a 70 cm bore 3 teslas MRI, EF volume (EFV) and myocardial triglyceride content (MTGC) in morbid obese patients, in order to determine whether these ectopic fat depots accumulate similarly, are linked to metabolic disorders or to myocardial function.
Materials and methods: 57 subjects with normal LV function and no coronary artery disease, (33 lean, and 24 obese patients (9 with type 2 diabetes) (BMI= 21.4 ± 2 and 42.3 ± 6 kg/m^2)) were studied by MRI, and underwent anthropometric, biological and visceral abdominal fat (VAT) assessment. EFV was assessed volumetrically, and MTGC using H^1 spectroscopy.
Results and conclusions: EFV and MTGC were positively correlated ($r=0.47$, $p<0.0001$) even after VAT was accounted for ($p=0.005$), and were both strongly correlated with age, BMI, waist circumference (WC), and VAT. EFV was the only ectopic depot negatively correlated with thigh circumference/BMI ratio ($r=-0.68$, $p=0.0002$), suggesting that the development of EF is related to the lack of increase of subcutaneous fat with weight gain. We observed that the two cardiac depots did not accumulate similarly, as the ratio EFV/MTGC increased with diabetes and decreased with physical activity. Moreover, EFV and MTGC statistically increased between lean and obese patients ($p=0.002$, $p=0.006$), and there was a more twofold increase in EFV between obese and diabetics (123 ± 11 vs 240 ± 46 mL, $p=0.003$). EFV and MTGC were both strongly associated with metabolic syndrome ($p<0.0001$), and with metabolic risk markers (triglycerides $r=0.59$, $p<0.0001$; $r= 0.35$, $p=0.01$, HOMA-IR $r=0.44$, $p<0.003$; $r= 0.38$, $p=0.02$, and CRP $r=0.39$, $p<0.03$ and $r= 0.49$, $p=0.005$, respectively). However, when including VAT and EFV or MTGC together, only VAT remained statistically associated with metabolic parameters ($p<0.01$). Furthermore, EFV and MTGC were associated with parameters of cardiac function. Interestingly, MTGC was the only independent parameter associated with normalized end-diastolic and systolic volumes ($r=-0.37$, $p=0.02$ and $r= -0.42$, $p=0.01$), cardiac index ($r=-0.34$, $p=0.04$), and normalized stroke volume ($r=-0.34$, $p= 0.03$). To conclude, the developement of EFV and MTGC is not similar. EFV and MTGC are linked to metabolic disorders, but VAT remains the best predictor of metabolic risk. Lastly, our work reinforces the importance of cardiac steatosis, in that MTGC is associated with early myocardial dysfunction. It suggests that in an earlier stage of non ischemic cardiomyoapthy lipid oversupply to cardiomyocytes may lead to lipotoxic injury on myocardium.

59

Role of pancreatic fat in beta cell dysfunction and diabetes
I. Lingvay[1], J.L. Legendre[1], B. Adams-Huet[2], S. Zhang[2], L.S. Szczepaniak[3];
[1]Endocrinology, University of Texas Southwestern Medical Center, Dallas, [2]Clinical Sciences, UT Southwestern, Dallas, [3]Cardiology, Cedar-Sinai Medical Center, Los Angeles, USA.

Background and aims: Fat accumulation in the beta-cells is thought to contribute to the pathogenesis of beta-cell dysfunction and the development of diabetes, at least in animal models. We explored the relevance of this hypothesis in the pathogenesis of diabetes in humans by evaluating the relationship between total pancreatic fat content (panTG) and insulin secretion in vivo in human volunteers.
Materials and methods: We enrolled 91 volunteers, with and without diabetes, with an average age of 41.2 years, and body mass index (BMI) of 32.9 kg/m2. PanTG and visceral fat area were measured in vivo by magnetic resonance spectroscopy and imaging, respectively; beta-cell function was measured using a frequently sampled glucose tolerance test. Acute insulin response (AIR) is a measure of first phase insulin secretion, while the disposition index (DI) is a measure of insulin secretion adjusted for the prevailing insulin sensitivity. DI is a good indicator of disease progression, as it decreases from normal (>1000) in patients with normal glycemia, to very low (<400) in those who have progressed to diabetes. Non-normally distributed variables were transformed. To compare panTG across DI groups while adjusting for age and BMI we used ANCOVA analysis. Multivariate regression analysis was performed for the dependent variable AIR, most representative models are shown in the figure.
Results: PanTG increased significantly across groups as DI worsened, even after adjusting for age and BMI ($p=0.01$). PanTG was highest in the group with the lowest DI, at 7.37 (+/-5.9) f/w% (panel A). PanTG, along with age, hip/waist ratio, and BMI were significant independent predictors of AIR (panel B - model 2). Visceral fat area was not a significant predictor of AIR when analyzed along with the same variables (panel B - model 3).
Conclusion: PanTG content is a significant contributor to beta-cell dysfunction, and ultimately development of diabetes, independent of visceral fat.



A: Pancreatic TG content by DI groups.

Model	Variable	Parameter Estimate	P-value	Adjusted R^2
Model 1	Age	-0.404	0.0002	0.304
	Hip/waist	-21.898	0.037	
	BMI	0.604	0.0003

Altered microRNAs expression is associated with insulin resistance status in high fat diet fed mice
S. Calderari[1], M. Diawara[1], S. Dubois[1], J.F. Fearnside[2], P.J. Kaisaki[2], C.M. Lindgren[2], D. Gauguier[1,2];
[1]Centre de Recherche des Cordeliers - UMRS 872, Paris, France, [2]The Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

Background and aims: Disturbances of microRNAs (miRs) expression or function play a role in several aspects of metabolism and glucose homeostasis. We have previously shown alterations in expression of miRs in insulin target tissues in the GK rat model of spontaneous type 2 diabetes, when com-

pared to normoglycaemic control strains. Investigations in our group in control mouse strains have demonstrated that high fat diet (HFD) feeding promotes the development of insulin resistance, obesity and fatty liver in 129S6 and C57BL6/J mice, whereas BALB/c are resistant to these experimentally induced phenotypes. The objective of the present work is to further study the implication of miRs in insulin resistance in two insulin target tissues (liver and adipose tissue) in these mouse strains.
Materials and methods: At five weeks, male mice of C57BL6/J, BALB/c and 129S6 were fed a normal carbohydrate diet (CHD) containing 5% fat, 19% protein, and 3.5% fibre or 40% HFD containing 32% lard oil and 8% corn oil ad libitum. At five months, liver and white adipose tissue were dissected (n=3-5), total RNA extracted and the expression of miR-125a, miR-27a, miR-222 and miR-29a were determined using ABI's taqman microRNA assays.
Results: 1/ When fed CHD, the expression of the four miRs was significantly higher in adipose tissue than in liver in the three mouse strains. Only miR-29a showed lower expression ($p<0.05$) in adipose tissue than in liver in 129S6 mice. 2/ When fed CHD, expression of miRs were highly variable between the 3 strains in both liver and adipose tissue. 3/ In HFD-fed 129S6 mice, expression of both miR-125a and miR-27a was upregulated in both liver (x4.6, $p<0.05$ and x2.1) and adipose tissue (x2.5, $p<0.05$ and x1.3). Tissue-specific miR over-expression was observed in liver for MiR-222 (x3.4, $p<0.05$) and in adipose tissue for miR-29a (x1.5). 4/ In HFD-fed C57BL6/J mice, miR-125a expression was not altered neither in liver nor adipose tissue. In response to HFD, expression of miR-27a was increased in liver (x2.4) and decreased in adipose tissue (-2.3). MiR-222 was over-expressed in liver (x3.4, $p<0.05$) and not altered in adipose tissue. Expression of miR-29a was unaffected in liver and decreased in adipose tissue (-1.6). 5/ In HFD-fed BALB/c mice, expression of miR-125a and miR-222 was not altered neither in liver nor adipose tissue. Expression of miR-29a was unchanged in liver and increased in adipose tissue (x1.4). Expression of miR-27a was unchanged in liver, but decreased in adipose tissue (-1.6).
Conclusion: Our results demonstrate the complex tissue- and strain-specific regulation of miRNA expression in experimentally induced insulin resistance, obesity and fatty liver disease. We observed a distinct correlation between miR altered expression and the metabolic status of HFD-fed mice. The 129S6 strain, very sensitive to HFD-induced glucose intolerance and obesity, exhibited miR over-expression in 75% of cases, whereas BALB/c, which is relatively resistant to HFD, showed miR altered expression in only 25% of cases. Our results provide strong evidence supporting a role of miR on impaired glucose homeostasis in models of spontaneous (GK) and experimentally induced (129S6) insulin resistance.

Adeno-associated-mediated nerve growth factor gene transfer prevents the development of heart microangiopathy and cardiomyopathy in mice
C. Emanueli[1], A. Caporali[1], L. Zentilin[2], P. Madeddu[1], M. Giacca[2], M. Meloni[1];
[1]Experimental Cardiovascular Medicine, University of Bristol, United Kingdom, [2]Molecular Medicine Laboratory, International Centre for Genetic Engineering and Biotechnology, Trieste, Italy.

Background and aims: Diabetes mellitus (DM) can cause cardiac dysfunction and heart failure independently of other risk factors like hypertension and myocardial infarction. The neurotrophin nerve growth factor (NGF) exerts cardioprotective effects but it is downregulated in the diabetic heart. The present study challenged the hypothesis that NGF gene transfer (GT) could prevent diabetes-induced cardiac dysfunction.
Materials and methods: Type-1 DM was induced in CD1 mice by streptozotocin injection (40 mg/Kg/day IP for five days). Two weeks later, GT with an adeno-associated vector serotype 2 carrying human *NGF* in the expression cassette (*AAV-2-hNGF*) or with an empty vector (*AAV-2-βGal*) was performed. Constructs were delivered into the left ventricle (LV) by 4 injections (total dose of $1x10^{11}$ pfu). Age-matched normoglycemic mice injected with *AAV-2-βGal* were used as controls.
Results: X-Gal staining confirmed successful GT of LV. Moreover, hNGF transgene expression was detected in plasma by ELISA at 12 weeks. Echocardiography (Visual Sonics) at 12 weeks after GT showed a deterioration of systolic function in diabetic mice (LV ejection fraction: 64.6±3.8 vs 73.1±6.9% in healthy controls; LV fractional shortening: 35.3±2.8 vs 42.5±6.3%; $P<0.05$ for both comparisons). In contrast, *AAV-2-hNGF* improved both LVEF and LVFS (113% and 121% respectively) as compared to diabetic controls ($P<0.05$ for both comparisons; N.S. vs healthy). Moreover, *AAV-2-hNGF* improved LV systolic pressure (LVSP) and contractility (expressed as dP/dt_{max} and dP/dt_{min}) measured by Millar catheter (LVSP: 76±4 vs 61±5 mmHg in diabetic controls; dP/dt_{max} and dP/dt_{min}: 141% and 149% of diabetic controls, respectively; $P<0.01$ for all comparisons). In addition, *AAV-2-hNGF* prevented enlargement of end-diastolic LV chamber volume (74±11 vs 89.1±13 µl in diabetic controls; $P<0.05$) and maintained the end-diastolic LV internal diameter (4.1±0.3 vs 4.4±0.3 µl in diabetic controls; $P<0.05$). Analyses in histological heart sections at 12 weeks indicated that diabetes induced microvessel rarefaction in the myocardium. By contrast, *AAV-2-hNGF* preserved capillary (measured as isolectin-B4 positive vessels) and small (diameter <50µm) arteriole (measured as isolectin-B4 and α-smooth muscle actin double positive vessels) densities in the hearts of diabetic mice (4255±222 vs 3440±155 capillaries/mm^2 in diabetic controls; $P=0.05$; 50±15.8 vs 37±13.9 arterioles/mm^2 in diabetic controls; $P=0.05$). Finally, as measured by fluorescent microspheres, DM reduced LV blood flow (0.39±0.1 vs 0.59±0.1 mL/min/g of tissue in healthy controls; P=NS), which was prevented by *AAV-2-hNGF* (0.69±0.1 mL/min/g of tissue; $P=0.05$ vs diabetic controls).
Conclusion: These results provide evidence that prolonged NGF overexpression prevents LV dysfunction and heart failure in the mouse diabetic heart and it also preserves cardiac microvasculature in the settings of diabetic cardiomyopathy.

VEGF and CD36 are potential players in the crosstalk between perivascular fat and human smooth muscle cells
R. Schlich, D. Lamers, H. Sell, J. Eckel;
Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, Germany.

Background and aims: The increase of fat mass in obesity is an important risk factor for the development of atherosclerosis. Specifically, perivascular fat in connection with obesity and the metabolic syndrome might be an activator of inflammation and dysfunction of the vessel wall. In previous studies we could show that adipocyte-conditioned media (CM) induced proliferation and migration of human smooth muscle cells with a concomitant increase in ICAM-1 expression. The combination (CMOA) of CM and oleic acid (OA) enhanced the proliferation in a synergistic way. CMOA induced

iNOS Expression, NO production and variable pro-inflammatory and proliferative signalling pathways. The aim of this study is to identify factors and mechanism, which are responsible for the effect of CM and the synergism with OA on the proliferation of smooth muscle cells.
Materials and methods: CM was generated from human *in vitro* differentiated human adipocytes and analysed for its content in adiponectin, IL-6 and VEGF. Proliferation of human coronary artery smooth muscle cells was measured via BrdU incorporation into DNA.
Results: The content of VEGF correlated significantly with the proliferative effect of CM (n=17, r=0.79, p=0.002) while adiponectin correlated negatively with CM-induced proliferation (n=22, r=-0.465, p=0.029). VEGF alone showed a 2.5-fold augmentation of proliferation and the combination of VEGF and OA (VEGFOA) act additive (5-fold). Incubation with CMOA induced a 2-fold increase of VEGF concentration compared with CM or OA alone, indicating that smooth muscle cells significantly contribute to proliferation by releasing VEGF for an autocrine/paracrine stimulation. Blocking VEGF with a specific antibody reduced the proliferative impact of CM, VEGF, OA, and VEGFOA significantly to control levels (CM=97 ±5 %, VEGF=106 ±5 %, OA=90±9 %, VEGFOA= 125±12 %). In contrast, VEGF-blocking was not sufficient to reduce CMOA-induced proliferation to control levels (from 569±40 % to 262±30 %). As CM and VEGF both significantly increase the expression of CD36 and as CM -treatment predisposes for increased lipid accumulation after OA addition, we propose that CD36 might be an additional player in CMOA-induced proliferation in smooth muscle cells. CD36 belongs to the family of scavenger receptors and is also identified as a fatty acid transporter. Moreover it has been speculated, that CD36 might play a pro-atherogenic role as CD36 interacts with VEGF and its receptor. Silencing of CD36 reduced the proliferative effect of OA and VEGF to control levels (OA= 118±19 %, VEGF= 80±6 %) while CM- and CMAO-induced proliferation remained significantly higher compared to control (CM=164±18 %, CMOA=257±30 %). Combining the silencing of CD36 with VEGF blocking, CMOA-induced proliferation could be reduced to only 150±7 % of the control level.
Conclusion: In this study we identified VEGF as an important factor for the proliferative effect of CM. The increase of CD36 expression by treatment with CM and VEGF could represent a key mechanism, how CM and OA synergistically increase proliferation and inflammatory signalling in smooth muscle cells. Further work is intended to elaborate how increased CD36 and lipid accumulation in smooth muscle cells are involved in the crosstalk between perivascular adipose tissue and the vessel wall.

Increased expression of TIMP3 protects against diabetes and atherosclerosis

M. Federici[1], V. Casagrande[1], R. Menghini[1], A. Marino[1], M. Cavalera[1], S. Menini[2], G. Pugliese[2], D. Lauro[1], P. Sbraccia[1], R. Lauro[1];
[1]Dept. of Internal Medicine, University of Tor Vergata, [2]University La Sapienza Rome, Italy.

Background and aims: Tissue inhibitor of Metalloproteinase 3 (TIMP3), an inhibitor of TNF-alpha Convertase (ADAM17) and other metalloproteinases is decreased in atherosclerotic plaque from patients with Type 2 diabetes and in tissues of humans and mice affected by obesity.
Materials and methods: Because obesity and atherosclerosis are associated with increased macrophage accumulation in different tissues, we used a transgenic approach under control of CD68 promoter to reconstitute TIMP3 levels to analyze the effects on metabolic and vascular homeostasis, using Diet Induced Obesity (DIO) to analyze the effect on insulin resistance and LDLR-/- background combined with atherogenic diet to analyze the effect on atherosclerosis. Transgenic (Tg) mice were identified by RT-PCR and confirmed by Southern blot. In Tg mice, TIMP3 overexpression was confirmed by RT-PCR, Western blot and Reverse Zymography in spleen, liver, peripheral blood monocytes and bone marrow derived macrophages, treated or not with LPS.
Results: In the DIO model, after 20 weeks of High Fat Diet (HFD), we observed that Tg mice compared with WT littermates showed a significant improved glucose tolerance and insulin sensitivity, measured by IPGTT and IPITT (p<0.01 for all, n=8 per group); a study of Fluoro-Deoxy-Glucose (FDG) uptake in combination with insulin infusion through Positron Emission Tomography scan (FDG-PET scan) revealed increased insulin induced glucose uptake in forelimbs of Tg mice compared with WT littermates (p<0.05, n=6 per group). Insulin, leptin, AST and ALT were lower and adiponectin increased in Tg mice compared with WT littermates (p<0.01 for all, n=8 per group). CT scan revealed significant reduction of visceral adipose tissue in Tg compared with WT littermates (p<0.05; n=3 per group). Histology of white adipose tissue (WAT), liver, kidney and aorta showed accumulation of lipids, intense fibrosis and increased inflammatory markers in WT compared with Tg mice. Tg revealed also significant reduction in adipose tissue vascularization (CD31 staining, p<0.05); however, mean adipocyte area was reduced in Tg compared with WT mice (p<0.01). Expression profiling for metabolic and inflammatory genes revealed that Tg compared with WT have significant higher levels for Adiponectin/CEBPalpha/PPARgamma/betaKLOTHO/FABP4/SOD1 (p<0.01 for all) and lower levels for MCP1/F4/80/SOCS3/Pref1/GP47/GP67 in WAT. In the liver TG showed increased Il-10 with decreased G6Pase/Socs3/GP47/GP67/Il-6 in liver (p<0.01 for all, n=5). Next we analyzed the effect of Timp3 overexpression in the LDLR-Tg and LDLR knockout mice fed Western Diet for 12 weeks. Histology of aortic roots from LDLR-Tg mice revealed 60% reduction in plaque surface (p<0.001), reduced F4/80, CD3 and nitrotyrosine staining (p<0.01 for all), increased collagen content and no necrotic cores, when compared to LDLR littermates (n=5 per group). Gene expression profiles in liver and aorta suggest reduced oxidative stress and less activation of inflammatory pathways in LDLR-Tg compared to LDLR mice.
Conclusion: Our data indicate that macrophage specific overexpression of TIMP3 protects from metabolic inflammation and related metabolic disorders such as insulin resistance, glucose intoleramce and atherosclerosis.

Glucagon-like peptide-1 inhibits H2O2-dependent JNK phosphorylation and apoptosis in human cardiac progenitor cells

A. Leonardini, L. Laviola, V. Galleggiante, M. Melchiorre, M.R. Orlando, A. Natalicchio, S. Perrini, F. Giorgino;
Endocrinology & Metabolic Diseases, D.E.T.O., University of Bari, Italy.

Background and aims: The heart possesses a compartment of multipotent cardiac progenitor cells (CPCs), which provides a constant tissue renewal. Increased CPC apoptosis has been proposed as a mechanism of myocardial dysfunction, leading to heart failure. Glucagon-like peptide-1 (GLP-1) is an incretin hormone secreted by the small intestine in response to nutrient ingestion. There is growing evidence suggesting that GLP-1 may regulate cardiac function and promote survival of cardiac cells in environmental stress conditions. The aim of this study was to investigate the protective effects of GLP-1 on H2O2-induced apoptosis in CPCs isolated from adult human heart biopsies, obtained from the auricle in the course of open heart surgery.
Materials and methods: Biopsy-obtained cells showed typical features of mesenchymal multipotent cells, including the ability to proliferate up to the 15th passage, and the differentiation potential toward the osteogenic and chondrogenic lineages. Analysis of CD105, c-kit, CD34, CD31, CD133, and CD45 by flow cytometry, and lineage-specific intracellular markers by quantitative real-time PCR, including GATA-4 and MEF-2C, confirmed that the isolated cells represent resident cardiac progenitors. Alpha-MHC transcripts, which characterize differentiated cardiac cells, were undetectable. Expression and activation levels of the proteins under investigation were evaluated by immunoblotting techniques.
Results: Exposure of CPCs to 0.5 mM H2O2 for 20-120 min induced a 2-fold increase in cell apoptosis, measured by evaluation of cytosolic oligosomes (p<0.05) and cleaved caspase-3 (p<0.05). Exposure to H2O2 induced a 3-fold increase in the phosphorylation of Erk1/2 (p<0.05), a 1.5-fold increase in the phosphorylation of JNK1/2 (p<0.05) and a 6-fold increase in the phosphorylation of Akt (p<0.05). When JNK activation was inhibited using the specific inhibitor SP600125 (10 μM), H2O2-dependent JNK phosphorylation appeared to be prevented, and H2O2-induced apoptosis was decreased by 40% (P<0.05). SP600125 also inhibited the phosphorylation of the JNK substrate c-jun, but had no effects on the JNK upstream kinases MKK-4 and MKK-7. Preincubation of CPCs with 20 nM GLP-1 for 16 h inhibited both H2O2-induced activation of JNK 1/2 (p<0.05 vs. H2O2-treated CPCs) and apoptosis (p<0.05 vs. H2O2-treated CPCs). GLP-1 incubation had no evident effect on Akt and Erk1/2 phosphorylation in response to H2O2. However, exposure of CPCs to GLP-1 (10-20 nM) was associated with a significant increase in the phosphorylation of the PKA-dependent transcription factor CREB.
Conclusion: Thus, GLP-1 prevents H2O2-mediated apoptosis in human CPCs, at least in part by interfering with the activation of JNK. A direct pro-survival mechanism in myocardial progenitor cells may contribute to the observed protective effects of GLP-1 on the heart.

Octyl-D-carnosine attenuates atherosclerosis and renal disease in ApoE null mice fed a western diet

S. Menini[1], C. Iacobini[1], C. Ricci[1], A. Scipioni[1], C. Blasetti-Fantauzzi[1], A. Giaccari[2], E. Salomone[2], A. Lapolla[3], M. Orioli[4], G. Aldini[4], G. Pugliese[1]; [1]Department of Clinical Sciences, La Sapienza University, Rome, [2]Department of Endocrinology, Catholic University, Rome, [3]Department of Medical and Surgical Sciences, University of Padua, [4]Institute of Pharmaceutical and Toxicological Chemistry, University of Milan, Italy.

Background and aims: Reactive carbonyl species generated by oxidation of endoperoxides in lipoproteins react with proteins to form advanced lipoxidation endproducts (ALEs), which have been implicated in both atherosclerosis and renal disease. L-carnosine was shown to act as a quencher of reactive carbonyl species, but, in humans, it is rapidly inactivated by carnosinase. This study evaluated the effect of carnosinase-resistant octyl D-carnosine (ODC) on the development of atherosclerosis and renal disease in the apoE null mouse model.
Materials and methods: Adult female ApoE null mice, fed either a western, pro-atherogenic, high fat diet (HFD, 42% fat, 0.2% cholesterol) or a standard, normal fat diet (NFD), were treated with ODC (Flamma SpA, Chignolo d'Isola, BG, Italy; 60 mg/kg body weight in the drinking water) or vehicle for 12 weeks. Aortic and kidney lesions were evaluated, together with expression of inflammatory and disease progression markers.
Results: ODC-treated HFD-fed mice showed significantly reduced lesion area at the level of the aortic sinus (434.9±49.9 vs. 527.9±49.6 μm x 10^{-3}, P<0.01) and, particularly, of the brachiocephalic artery (22.3±4.4 vs. 43.3±6.5 % of luminal occlusion, P<0.01), as compared with untreated animals. Treatment also produced a more stable plaque phenotype, with less foam cell accumulation, inflammation and apoptosis and increased clearance of apoptotic bodies, resulting in reduced necrotic core formation (11.8±3.8 vs. 25.3±5.4%, P<0.001). Fibrosis was increased (42.6±5.8 vs. 28.7±7.8 % of lesion area, P<0.01) and disruption of vessel wall architecture was reduced, with less elastin degradation and pseudo-microaneurysm formation. Oil red O staining of *en-face* aorta preparations showed a significantly reduced lipid accumulation in ODC-treated vs. untreated HFD-fed ApoE null mice (13.2±2.5 vs. 19.2±2.0%, P<0.001). Increases of protein content of F4/80, and CXCR3 as well as of mRNA expression of F4/80, CXCR3, VCAM-1, MCP-1, TNF-α, IFN-γ, MMP-9, and CHOP were significantly lower (or even normalized) and those of anti-inflammatory IL-4 and Il-10 significantly increased in ODC-treated versus untreated HFD-fed mice. This was associated with reduced tissue content of HNE adducts, oxLDLs, and nitrotyrosine and mRNA expression of the ALE-receptors CD36, TLR-2 and 4, RAGE and galectin-3 in HFD-fed ODC-treated versus untreated ApoE null mice. Likewise, renal lesions were significantly attenuated in ODC-treated versus untreated HFD-fed mice on HFD, with lower foam cell accumulation, inflammation, apoptosis, glomerular and tubulo-interstitial fibrosis, content of HNE adducts, oxLDLs, and nitrotyrosine and expression of pro-inflammatory and pro-fibrotic mediators. Serum ALE, pentosidine, carbonylated proteins, and isoprostane-8-epi-$PGF_{2\alpha}$ levels were also lower in ODC-treated vs. untreated HFD-fed ApoE null mice.
Conclusion: These data support a central role for lipoxidation in atherosclerosis and renal disease and indicate that quenching of carbonyl adducts with a D-carnosine ester may represent a promising approach to the prevention and treatment of these disorders.

Methylglyoxal-mediated cardiovascular cell dysfunction: role of poly (ADP-ribose) polymerase

O.J. Bates[1], J.G. Mabley[2]; [1]Brighton and Sussex Medical School, [2]School of Pharmacy & Biomolecular Sciences, University of Brighton, United Kingdom.

Background and aims: Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound, has been implicated in cardiovascular complications of diabetes. MGO reacts with many short and long-lived cellular proteins disrupting their synthesis and function which may lead to increased cellular oxidative stress. Overactivation of the DNA repair enzyme poly (ADP-ribose) polymerase (PARP) following oxidative stress-induced DNA damage with subsequent depletion of cellular high energy phosphate and NAD levels has been implicated in endothelial cell dysfunction in diabetes. The aims of this study were twofold, firstly to determine whether MGO-mediated activation of PARP was responsible for the observed cardiovascular cell dysfunction and hence the link between hyperglycaemia and PARP activation already reported in cardiovascular cells. Secondly, to determine whether the cardioprotective agent, resveratrol could protect against MGO-mediated dysfunction.
Materials and methods: The effects of MGO on acetylcholine-mediated NO dependent vasorelaxation were tested using ex vivo rat aortic rings exposed to 0.1, 0.3 and 1 mM MGO for 1, 2 and 4h. The role of PARP activation in MGO-mediated dysfunction was evaluated by the co-administration of the specific PARP inhibitor PJ34 (10 μM) with MGO (0.3 mM). The effect of the cardiovascular protective agent resveratrol (3 μM) on MGO-mediated cardiovascular cell dysfunction was also determined. MGO effects on cardiac H9c2 myocyte cell viability was measured by MTT assay and oxidative stress was measured using the NBT assay.
Results: MGO dose and time dependently caused endothelial cell dysfunction, 0.1 mM MGO had no effect on endothelial cell-mediated vascular relaxation following 1, 2 or 4h exposure, whereas 0.3 and 1 mM though having no effect at 1h exposure, caused significant endothelial cell dysfunction at both 2 and 4h. Exposure of aortic rings for 2h to MGO (0.3 mM) increased the IC50 for acetylcholine-mediated relaxation from 15±3 nM to 82±4nM (p<0.01), no further damage was seen either with 1 mM MGO or an increased exposure time (4h). Simultaneous exposure of aortic rings to MGO (0.3 mM) and the PARP inhibitor PJ34 (10 μM) for 2h protected against the MGO-mediated dysfunction significantly reducing the acetylcholine IC50 from 81±5 nM to 18±4 nM (p<0.01 vs. MGO alone), also simultaneous application of resveratrol (3 μM) also protected endothelial cell function reducing the IC50 to 19±6 nM (p<0.01 vs. MGO alone). MGO dose dependently reduced H9c2 myocyte cell viability following 24h exposure. Simultaneous addition of resveratrol increased H9c2 cell viability from 28±0.5% with 0.8 mM MGO alone to 36±2%, 51±2% and 54±1% with 1, 3 and 10 μM respectively (p<0.05 vs. MGO alone). Exposure of H9c2 cells to MGO for either 4 or 6h significantly increased cellular oxidative stress. MGO at 1 mM increased oxidative stress by 25±11% and 46±12% above untreated cells following 4 and 6h exposure respectively (p<0.05 vs. untreated cells).
Conclusion: MGO exposure causes both endothelial and myocyte cellular dysfuction, effects which appear to be mediated by increased cellular oxidative stress and activation of PARP. Resveratrol also appears to confer a protective effect against MGO-mediated endothelial and myocyte cellular dysfunction.

OP 12 Metabolic control of beta cells

67

Is G6PC2/IGRP a component of the beta cell glucose sensor?

L.D. Pound, Y. Wang, J. Oeser, O.P. McGuinness, R.M. O'Brien;
Molecular Physiology and Biophysics, Vanderbilt University, Nashville, USA.

Background and aims: Glucose-6-phosphatase catalyzes the hydrolysis of glucose-6-phosphate (G6P) to glucose and inorganic phosphate. The glucose-6-phosphatase catalytic subunit (G6PC) gene family comprises three members, G6PC, G6PC2 and G6PC3. G6PC, also known as G6Pase, is predominantly expressed in liver and kidney where it catalyses the terminal step in the gluconeogenic and glycogenolytic pathways. G6PC2, previously known as the islet-specific glucose-6-phosphatase catalytic subunit related protein (IGRP), is selectively expressed in insulin producing beta cells. In vitro, G6PC2 hydrolyzes G6P at a much lower rate than G6PC raising the question as to whether G6P is a physiologically important substrate for this protein.
Materials and methods: To assess the physiological importance of G6pc2, we have generated G6pc2-null mice, backcrossed onto a C57BL/6J background, and performed a phenotypic analysis focusing primarily on energy metabolism and pancreatic hormone secretion.
Results: 16 week old G6pc2 KO mice on a chow fed diet exhibit no differences in body weight and no gross anatomical or behavioral changes. However, following a 6 hour fast, a decrease in blood glucose was observed in both male (WT: 130.7+/-3.6; KO: 109.2+/-3.5; $p<0.001$) and female (WT: 121.9+/-4.3; KO: 104.3+/-4.4; $p<0.01$) G6pc2 KO mice relative to wild type (WT) littermates, while plasma insulin and glucagon concentrations were unchanged. Because glycolytic flux has been shown to determine the S0.5 of glucose-stimulated insulin secretion (GSIS) these observations are consistent with a model in which the glucose-6-phosphatase activity of G6PC2 opposes the action of glucokinase and thereby modulates the S0.5 of GSIS. Deletion of the G6pc2 gene is therefore predicted to abolish glucose cycling, increase glycolytic flux and lower the S0.5 of GSIS. Additional studies were performed to explore this concept. Pancreas perfusion experiments in which islets were challenged with variable glucose concentrations demonstrated that deletion of G6pc2 results in a leftward shift in the S0.5 of GSIS. A similar shift was observed in islet perifusion experiments. In addition, following static incubation of islets in a sub-maximal 11 mM stimulatory glucose concentration, islets isolated from G6pc2 KO mice displayed enhanced GSIS relative to islets isolated from WT mice (WT: 0.899 (%content/30 min)+/-0.142; KO: 2.116+/-0.204; $p<0.01$). Finally, intraperitoneal glucose tolerance tests, again using a submaximal stimulatory glucose concentration, demonstrate that G6pc2 KO mice do not have enhanced glucose tolerance but rather lower blood glucose at all time points, a result that is again consistent with G6pc2 regulating the S0.5 of GSIS.
Conclusion: The existing dogma in the islet field proposes that glucokinase is the beta cell glucose sensor. The significance of our observations is that they challenge this dogma and suggest that G6PC2 is a fundamental inhibitory component of that sensor. Instead we propose that a glucokinase/G6PC2 futile cycle acts as the beta cell glucose sensor determining glycolytic flux and hence the S0.5 of GSIS. This conclusion is consistent with genome wide association studies that have recently shown that single nucleotide polymorphisms in the G6PC2 gene are associated with variations in fasting plasma glucose levels in humans.

Identification of an intracellular metabolic signature impairing beta cell function

N. Sauter[1], I. Goehring[2], G. Catchpole[3], A. Assmann[2], K. Suessbauer[4], M. Moehlig[2], A.F.H. Pfeiffer[2], J. Oberholzer[5], L. Willmitzer[3], J. Spranger[2], K. Maedler[4];
[1]University Hospital Zurich, Switzerland, [2]Charite, Department of Endocrinology, Diabetes and Nutrition, Berlin, [3]Max Planck Institute of Molecular Plant Physiology, Potsdam, [4]Centre for Biomolecular Interactions, University of Bremen, Germany, [5]University of Illinois, Chicago, USA.

Background and aims: Chronic hyperglycaemia promotes the progressive failure of pancreatic β-cells in patients with diabetes mellitus, a clinically highly relevant phenomenon known as glucotoxicity. Assuming that changes of the intracellular metabolism contribute to this progressive β-cell failure, an unbiased metabolite profiling analysis was carried out to identify the metabolic signature of β-cells during high glucose exposure.
Material and methods: Isolated human islets and INS-1E cells were cultured at 5.5 to 33.3 mM glucose from 1 to 96 h with or without 6-aminonicotinamide (6-AN), a potent inhibitor of 6-phosphogluconic acid dehydrogenase. After the glucose pre-treatment, islets underwent an additional glucose challenge at 5.5 and 22.2 mM glucose and of p-ERK, glucose stimulated insulin secretion (GSIS), insulin mRNA were analysed. Metabolites were analysed in islet lysates on a Leco Pegasus 3 time-of-flight mass spectrometer (Leco). PCA was performed with MATLAB 7.0 (Mathworks).
Results: To identify potential novel mediators of insulin gene suppression by chronic high glucose treatment, an unbiased time course analysis of metabolites was performed in the β-cells INS-1E and in human islets, during which 73 metabolites were uniquely identified. Principal component analysis (PCA) revealed that prolonged exposure to high glucose caused clear differentiation compared to early time points thus demonstrating the differential impact of acute and chronic glucose exposure on the β-cell. The most important metabolites driving the separation from acute to chronic glucose were gluconic acid, glucono-delta-lactone and 6-phosphogluconic acid from the pentose phosphate pathway. The addition of 6-AN at low glucose, promoted the accumulation of the pentose phosphate metabolites thus partially reflecting the metabolic state of the β-cells under high glucose. Analysis of insulin mRNA revealed that 6-AN and the accompanied rise in pentose phosphate metabolites lead to a 3.5-fold decrease of insulin gene expression compared to low glucose alone, similarly as exposure to chronic high glucose for 3 days (3.3-fold decrease). Glucose-dependent regulation of insulin transcription is dependent on extracellular signal-regulated protein kinases (ERK1/2). ERK1/2 kinase is activated by acute glucose exposure. In contracts, we show here that pre-incubation of elevated glucose completely abolished a further glucose mediated ERK induction, which correlated with the loss of GSIS, suggesting that ERK stimulation, is essential for GSIS. Accumulation of pentose phosphate pathway metabolites in islets by 6-AN at low glucose concentrations, was able to promote ERK1/2 phosphorylation to a similar extent as long-term high glucose treatment, but also failed to maintain GSIS.
Conclusions: Based on unbiased metabolite analyses, the here presented insights provide novel perspectives in the therapeutic goal to preserve and potentially improve beta-cell function in patients with diabetes mellitus.

69

miR-29a, miR-29b and miR-124 contribute to pancreatic beta cell specific silencing of monocarboxylate transporter 1 (*Mct1/Slc16a1*)

G.A. Rutter, T.J. Pullen;
Dept. Cell Biology / Div. Diabetes, Endocrinology & Metabolism, Imperial College, London, United Kingdom.

Background and aims: Glucose metabolism in pancreatic beta cells is specialised to efficiently couple glucose oxidation to ATP production, critical for stimulating insulin secretion. Alternative metabolic pathways that could interfere with glucose sensing are suppressed by specifically "disallowing" expression of certain genes in beta cells. For example, *MCT1* (*SLC16A1*) encodes a plasma membrane monocarboxylate (pyruvate/lactate) transporter which is widely expressed in other tissues but not in beta cells. The effects of inappropriate expression of *MCT1* are shown in the rare genetic disorder, Exercise Induced HyperInsulinism, linked to mutations in the *MCT1* promoter. During strenuous physical exercise, the presence of the transporter in affected individuals is presumed to allow circulating pyruvate to enter beta cells, resulting in inappropriate insulin release and consequent hypoglycaemia. We aimed here to identify the mechanisms by which expression of *MCT1* is specifically disallowed in beta cells. The *MCT1* promoter drives low but significant reporter gene expression in the MIN6 beta cell line suggesting that additional post-transcriptional mechanisms may be responsible for silencing this gene. We therefore investigated whether microRNAs (miRNA) expressed in beta cells contribute to the tissue specific silencing of this gene.
Materials and methods: Publicly available high throughput sequencing data from beta cells and thirteen other mouse tissues were interrogated to determine the abundance and specificity of microRNA expression. Potential miRNA binding sites within the *MCT1* 3′ UTR were identified using miRanda and PicTar algorithms. Hits were validated by luciferase assay on both human and mouse *MCT1* 3′ UTRs, and precise locations of binding sites confirmed by site-directed mutagenesis. Effects on endogenous *Mct1* expression were determined by stable expression of miRNAs in the hepatocyte-derived mhAT3-F cell line where *Mct1* mRNA is abundant.

Results: Bioinformatic analysis of miRNA expression in beta cells ranked all detected miRNAs by a combined abundance and specificity score, successfully identifying known beta cell specific miR-375 and miR-7 within the top three. Eight miRNAs were predicted to target the *Mct1* 3′ UTR, of which miR-29a, miR-29b and miR-124 produced large and significant decreases in expression by luciferase assay in HEK293 cells. All three miRNAs fall within the top third of miRNAs ranked by combined beta cell abundance and specificity score. Mutating the identified binding sites abolished the effect of miR-124 and miR-29b and significantly reduced the effect of miR29a by luciferase assay. Stable expression of miR-29a and miR-124 in mhAT3-F cells virtually abolished, and miR-29b considerably reduced expression of Mct1 protein. Mutating either binding site significantly increased expression of luciferase bearing the *Mct1* 3′ UTR in MIN6 beta cells, confirming these miRNAs are expressed at sufficient levels to downregulate *Mct1*.
Conclusion: Our interrogation of publicly available miRNA expression data provides a novel prediction of miRNAs important for beta cell function. Among these we identify miR-29a, miR-29b and miR-124 as capable of downregulating *Mct1* through a direct interaction with cognate binding sites in the 3′ UTR. We propose that the coordinated action of these miRNAs contributes to the beta cell specific silencing of *Mct1* required for efficient glucose sensing.

Inducible expression of Monocarboxylate Transporter 1 (Mct1/Slc16a1) in the beta cell of transgenic mice: a model of exercise induced hyperinsulinism
T.J. Pullen, G.A. Rutter;
Dept. Cell Biology / Div. Diabetes, Endocrinology & Metabolism, Imperial College, London, United Kingdom.

Background and aims: The plasma membrane monocarboxylate (pyruvate/lactate) transporter MCT1/SLC16A1 is expressed at vanishingly low levels in pancreatic beta cells but at high levels in other tissues. The absence of this transporter may serve a dual function. Firstly, it may prevent circulating pyruvate from entering the beta cell and inappropriately stimulating insulin secretion. In the rare dominant genetic disorder Exercise Induced HyperInsulinism (EIHI), linked to mutations in the *MCT1* promoter, pyruvate produced by muscle during vigorous physical exercise stimulates insulin secretion, resulting in hypoglycaemia. Secondly, by preventing loss of pyruvate generated by glycolysis, it may ensure that glucose is efficiently oxidised by mitochondria, generating ATP to trigger insulin secretion. While the mutations associated with EIHI increase expression of reporter genes in beta cell lines and patients exhibit increased MCT1 expression in fibroblasts, there is no direct evidence that MCT1 is over-expressed in patient beta cells. Here we have created a transgenic mouse model in which MCT1 is expressed in pancreatic beta cells and examine the impact on pyruvate or glucose tolerance *in vivo*.
Materials and methods: We established a transgenic mouse line in which a tetracycline-regulatable promoter controls expression of human *MCT1*, then crossed this with mice expressing the reverse-tetracycline transactivator (rtTA) under control of the rat insulin promoter. This permits beta cell-specific expression of *MCT1* upon addition of doxycycline only in mice bearing both transgenes. Littermates containing no transgenes were used as controls. *MCT1* expression was induced by administering doxycycline (1 g/l) in drinking water for at least 7 days. Glucose (1 g/kg body weight) or pyruvate (0.5 g/kg) were administered intraperitonealy following 16 hour fast, and blood glucose levels were measured.
Results: Following induction of *MCT1* expression, double transgenic (DT) mice showed a non-significant trend to lower fasting blood glucose relative to wildtype littermate controls (WT). Fasting blood glucose ± SEM: DT = 5.17 ± 0.34 mmol/l, n=13; WT = 6.24 ± 0.33 mmol/l, n=5; p= 0.091. In the absence of doxycycline there was no difference in the effect of pyruvate on blood glucose in DT v WT. Blood glucose 30 min after pyruvate challenge ± SEM: DT = 10.37 ± 0.45 mmol/l, n=13; WT = 9.90 ± 0.58, n=5; p=0.573). However, following doxycycline induction DT mice had significantly lower blood glucose: DT = 7.18 ± 0.40 mmol/l, n=13; WT = 8.78 ± 0.51 mmol/l, n=5; p=0.039. Thus, insulin secretion from beta cells appears to become sensitive to pyruvate in DT mice, lowering blood glucose. Interestingly, these mice also showed decreased glucose tolerance. Blood glucose 30 min after glucose challenge ± SEM: DT = 18.01 ± 0.87 mmol/l, n=11; WT = 13.16 ± 0.48 mmol/l, n=5; p=0.003). This is consistent with loss of pyruvate from beta cells lowering the yield of ATP from glucose metabolism hence reducing insulin secretion.
Conclusion: Expression of MCT1 in beta cells is sufficient to replicate the key feature of EIHI, as pyruvate challenge lowers blood glucose relative to controls. The demonstration that DT mice are also glucose intolerant reveals the importance of suppressed MCT1 expression in beta cells for normal glucose stimulated insulin secretion. Activating mutations in the *MCT1/SLC16A1* gene might also, therefore, increase susceptibility to type 2 diabetes.

Regulation of pyruvate dehydrogenase by phosphorylation in the pancreatic beta cell
D.A. Akhmedov, C.B. Wollheim, A.C. Wiederkehr;
Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: In the pancreatic beta-cell, glycolysis-derived pyruvate is taken up into the mitochondria where it is oxidized by pyruvate dehydrogenase (PDH; oxidative pathway) or carboxylated by pyruvate carboxylase, providing carbons to the TCA cycle (anaplerotic pathway). Recent studies suggest an important role of the anaplerotic pathway in glucose-stimulated insulin secretion. The relative flux through the two pathways in beta-cells may in part be determined by the PDH activity, which is regulated by phosphorylation/dephosphorylation of the E1 alpha subunit. Phosphorylation by PDH-kinases (PDK) leads to inactivation of PDH, while removal of phosphate by the calcium activated PDH-phosphatases (PDP) stimulates PDH activity. Here we have studied regulation of PDH by phosphorylation during glucose stimulation of the pancreatic beta-cell.
Materials and methods: INS-1E cells and rat islets were exposed to glucose or alternative secretagogues in the presence or absence of calcium signals. PDH phosphorylation was followed by Western-blotting, using an antibody specifically recognizing the phosphorylated (Serine-293) PDH E1 alpha subunit. The blots were then re-probed with an antibody for detection of total PDH E1 alpha protein. Expression of PDK isoforms (PDK1, PDK2, PDK3 and PDK4) in INS-1E cells was analyzed by RT-qPCR.
Results: Glucose stimulation leads to increase in mitochondrial calcium and thus would be expected to stimulate PDP resulting in dephosphorylation of PDH. Surprisingly, high glucose (16.7mM) or leucine (20mM) caused PDH E1 alpha phosphorylation in INS-1E cells and rat islets. A significant increase in phosphorylation was already observed after 5 minutes of glucose stimulation. This effect was also seen under conditions of blocked insulin secretion, ruling out the possibility that increase in PDH E1 alpha phosphorylation is a consequence of insulin receptor signaling. Preventing calcium signals during glucose stimulation further increased PDH E1 alpha phosphorylation while raising calcium by KCl (30mM) decreased phosphorylation. These findings are consistent with the known regulation of PDP activity by calcium. Under resting glucose (2.5mM) augmenting or depleting calcium did not affect PDH E1 alpha phosphorylation. This shows that nutrient stimulation and not calcium per se is the principal signal for PDH phosphorylation. We hypothesized that during glucose stimulation total PDK activity is more activated than the PDP activity leading to an enhanced PDH phosphorylation despite the glucose-stimulated mitochondrial calcium rise. We proceeded to determine the kinase (or kinases) responsible for the observed PDH E1 alpha phosphorylation. Expression of PDK1, PDK2 and PDK3 was detected in INS-1E cells. PDK4 was not detectable in this cell type. Remarkably, PDK3 transcript level was significantly higher than in any of the tested tissues, suggesting that this isoform may be particularly important in insulin-secreting cells.
Conclusion: PDH is rapidly phosphorylated following glucose stimulation in INS-1E cells and rat islets. Nutrient secretagogues regulate PDH phosphorylation and thereby determine to what extent the oxidative and anaplerotic pathways are utilized. Inactivation of PDH by phosphorylation should favor anaplerosis, which is required for the export of mitochondrial metabolites and may thereby affect the formation of mitochondria-derived coupling factors.

Glucose induces oscillations of the ATP/ADP ratio in individual beta cells
J. Li, E. Gylfe, A. Tengholm;
Department of Medical Cell Biology, Uppsala University, Sweden.

Background and aims: The ATP/ADP ratio has a central messenger function in β-cells, linking changes in glucose metabolism to electrical activity,

Ca^{2+} signaling and insulin secretion. Biochemical and electrophysiological analyses as well as single-cell and islet recordings of e.g. oxygen consumption, NAD(P)H fluorescence and mitochondrial membrane potential have provided evidence for metabolic oscillations in β-cells, but it has been difficult to directly demonstrate fluctuations of the ATP/ADP ratio. Application of the firefly luciferase bioluminescence assay in single β-cells is very challenging and has provided limited information about ATP rather than the ATP/ADP ratio. Using a novel fluorescence protein-based ATP/ADP ratio sensor, the aim of the present study was to monitor changes in ATP/ADP ratio in single glucose-stimulated β-cells.
Materials and methods: Circularly permuted fluorescent protein cpmVenus inserted into the T-loop of the ATP-binding bacterial protein GlnK1 (Perceval) was used as a cytoplasmic biosensor for ATP/ADP ratio in individual MIN6 β-cells. In some experiments the red fluorescent protein tdimer2 was used as a reference. Changes of cytoplasmic fluorescence were recorded with confocal microscopy.
Results: MIN6 β-cells expressed Perceval with essentially even distribution in the cytoplasm. The ATP-sensitivity of the probe was investigated after permeabilization of the plasma membrane with α-toxin. Changes of the medium concentration of ATP from 0 to 1, 3 and 10 mM resulted in concentration-dependent increase of Perceval fluorescence with half-maximal effect at about 3 mM ATP (n=9). Most intact cells showed stable fluorescence in the presence of 3 mM glucose. Application of 5 μM of the mitochondrial uncoupler FCCP dramatically diminished the Perceval fluorescence. Elevation of the glucose concentration from 3 to 20 mM induced oscillations of Perceval fluorescence with a frequency of 0.24±0.01 min^{-1} in >95% of the cells (n=107). In most cells (71%) the oscillations originated from an elevated level and the amplitude averaged 15±1% of the fluorescence in 3 mM glucose. The increase in ATP/ADP ratio was counteracted by rise of cytoplasmic Ca^{2+}, since hyperpolarization with the K_{ATP} channel activator diazoxide (250 μM) increased the Perceval fluorescence with maintenance of the glucose-induced oscillations (50%) or stable elevation. Moreover, membrane depolarization with 30 mM K^+ in the presence of 3 mM glucose caused pronounced decrease in Perceval fluorescence.
Conclusions: Glucose stimulation of MIN6 β-cells triggers oscillations of the cytoplasmic ATP/ADP ratio. Cytoplasmic Ca^{2+} negatively regulates the ATP/ADP ratio, but metabolic oscillations are maintained the absence of stimulated entry of Ca^{2+}.

OP 13 Incretin based therapies: new developments

Exenatide added to insulin glargine-treated patients with type 2 diabetes provided excellent fasting and postprandial control with weight loss and no increased risk of hypoglycaemia

R.M. Bergenstal[1], J.B. Buse[2], L.C. Glass[3], C.R. Heilmann[3], M.S. Lewis[3], A.Y.M. Kwan[4], B.J. Hoogwerf[4], J. Rosenstock[5];
[1]International Diabetes Center, Minneapolis, [2]UNC School of Medicine, Chapel Hill, [3]Eli Lilly and Company, Indianapolis, [4]Lilly USA, LLC, Indianapolis, [5]Dallas Diabetes and Endocrine Center, USA.

Background and aims: This is the first double-blind, placebo-controlled study adding exenatide (EXE) treatment in patients with type 2 diabetes suboptimally controlled (A1C ≥7.1 ≤10.5%) with basal insulin glargine therapy ± oral agents. The primary efficacy variable was change in A1C from baseline to 30 weeks. Prandial glycemic control measures included 7-point self-monitored blood glucose (SMBG) values, continuous glucose monitoring (CGM) data, and 1,5-anhydroglucitol (1,5-AG), a marker that is inversely proportional to average glycemia with greater sensitivity to postprandial (PP) excursion.
Materials and methods: A total of 259 patients (mean age 59 years, weight 94.4 kg, A1C 8.41%, diabetes duration 12.3 years, and insulin dose 48 U [0.51 U/kg]) were randomized to add either exenatide (10μg BID, n=137) or placebo (n=122) to insulin glargine therapy. Groups were generally comparable at baseline. At randomization, insulin dose was maintained (A1C >8.0%) or decreased by 20% (A1C ≤8.0%) for 5 weeks and then titrated to achieve a target fasting glucose of <5.6 mmol/L.
Results: At 30 weeks, A1C decreased by -1.71% to 6.70% with EXE treatment, and by -1.00% to 7.41% with placebo (PBO [p<0.001]). Endpoint fasting glucose values were not different between treatment groups (EXE 6.5±0.1, PBO 6.6±0.1 mmol/L, p=0.633). All non-fasting SMBG values were significantly lower for EXE (Figure). The 24-hour average glucose measurement from CGM (n=23) decreased in EXE by -3.2 to 6.6±0.4 mmol/L, and in PBO by -1.9 to 8.0±0.4 mmol/L (p=0.039). While baseline values of 1,5-AG were comparable between EXE and PBO (7.0±0.42 and 5.8±0.44 μmol/L, p=0.056), endpoint values were significantly higher for EXE than for PBO (12.7±0.5 vs 10.6±0.6 μmol/L, p=0.003). Weight decreased in EXE (-1.8±0.3kg, p<0.001) and increased in PBO (+1.0±0.3kg, p=0.011). Insulin dose increased more in PBO (20±2 U, p<0.001) than in EXE (13±2 U, p<0.001), (p=0.026 between groups). Minor hypoglycemia was similar for EXE and PBO (rate: 1.43±0.31 and 1.24±0.30 episodes/patient/year, p=0.666); major hypoglycemia (nocturnal) occurred twice in one PBO-treated patient. Adverse events were significantly greater for EXE vs PBO : nausea (41 vs 8%), diarrhea (18 vs 8%), vomiting (18 vs 4%), headache (14 vs 4%), and constipation (10 vs 2%).
Conclusion: To our knowledge, this is the first report of a controlled trial using a GLP-1-receptor agonist with basal insulin. Addition of EXE therapy in patients treated with insulin glargine improved A1C by contributing a prandial effect with no increased risk of hypoglycemia.

Response at 3 months to insulin dose decisions made at exenatide initiation in the Association of British Clinical Diabetologists (ABCD) nationwide exenatide audit

K.Y. Thong[1], R.E.J. Ryder[1], B. Jose[1], T. Sathyapalan[2], W. Shafiq[2], A. Rigby[2], C. Walton[2], ABCD Nationwide Exenatide Audit Contributors;
[1]City Hospital, Birmingham, [2]Hull Royal Infirmary, United Kingdom.

Background and aims: To learn from experience of exenatide in real clinical use in the UK, ABCD began a nationwide audit in December 2008. Though exenatide is not licensed for use with insulin many contributors to the audit used the combination. There is uncertainty about what should be done with insulin dose when exenatide is added. We therefore studied the response at 3 months after exenatide initiation in relation to insulin dose decisions made when exenatide was started.
Materials and methods: Patients were analysed according to three groups at initiation: non-insulin users (Group 1), insulin users in whom insulin was stopped (Group 2), and insulin users with insulin continued (Group 3). Group 3 was divided further into groups who had insulin doses unchanged, reduced by 1-40% (mean dose reduction 25.3%), 41-60% (mean 49.7%) and 61-99% (mean 67.4%) for further analyses. HbA1c and weight changes were compared within and across groups at baseline and 3 months. Correlation between insulin dose reduction and HbA1c and weight changes were assessed. Differences in group characteristics were examined.
Results: Amongst 6717 patients in the audit, exact data on diabetes treatment at baseline and initiation as well as suitable HbA1c and weight data were available for 2575 and 2454 patients respectively. The distribution in each group (HbA1c data, weight data) was: Group 1 (1626, 1545), Group 2 (275, 271) and Group 3 (674, 638). Mean age (54.1, 54.8, 55.0yrs), BMI (40.0, 39.3, 40.3kg/m^2), and initial HbA1c (9.5, 9.7, 9.6%) were not statistically different between groups. Group 2 had lower baseline weight than Group 1 (110.8 v 114.6kg, p=0.009). Group 2 had longer diabetes duration than Group 1 (10.8 v 8.3yrs, p<0.001), but lesser duration (10.8 v 12.3yrs, p<0.001) and total insulin dose (92 v 121U, p<0.001) compared with Group 3. Group 1 and 3 achieved significant HbA1c reductions (-0.95%, -0.53%, both p<0.001), but not Group 2 (-0.01%, p=0.948). 48% in Group 2 had HbA1c increases, with 15% ≥ 2.0%. All 3 groups achieved weight reductions (-3.7, -6.6 and -4.3kg, all p<0.001). Across groups, Group 2 achieved no HbA1c benefit compared with Group 1 and 3 (both p<0.001) but the most weight benefit (both p<0.001). Group 3 had intermediate results showing less HbA1c reduction but more weight loss than Group 1 (p<0.001, p=0.007 respectively). Among Group 3, weight reduction, but not HbA1c change, correlated with total insulin dose reduction (p=0.003, p=0.158 respectively). Subgroup analyses revealed the group with average insulin dose reduction of around half, and two-thirds, achieved more weight loss than the group with no dose changes (p=0.010, and p=0.037) or average dose reduction of a quarter (p=0.018, and p=0.035 respectively). Analyses on HbA1c changes among different insulin dose reduction groups did not reveal any significant differences. No severe hypoglycaemia was recorded in Group 3.
Conclusion: Our analysis shows that continuing insulin at exenatide initiation was safe and yielded HbA1c and weight reductions. Progressive insulin dose reductions yielded increasing weight loss but at the expense of HbA1c reduction, although there was no clear threshold when glycaemic reduction was negatively affected. When insulin was substituted, rather than combined with exenatide, almost half of patients had worsened glycaemic control.

Superior glycaemic control with taspoglutide, a once-weekly human GLP-1 analogue, compared with twice daily exenatide in type 2 diabetes: the T-emerge 2 Trial

G.B. Bolli[1], J. Rosenstock[2], B. Balas[3], B. Charbonnel[4], M. Boldrin[5], R. Ratner[6], R. Balena[3];
[1]University of Perugia, Italy, [2]Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA, [3]F. Hoffmann-La Roche, Basel, Switzerland, [4]Universite de Nantes, France, [5]Roche Pharmaceuticals, Nutley, [6]MedStar Research Institute, Hyattsville, USA.

Background and aims: Taspoglutide is a once-weekly (QW) human GLP-1 analog in Phase 3 development. T-emerge 2 compared the safety and efficacy of QW taspoglutide (Taspo) with twice-daily (BID) exenatide (Exe) in adult patients with type 2 diabetes (T2DM) inadequately controlled with metformin+/-thiazolidinedione.
Materials and methods: In this multinational, open-label study, 1149 subjects were randomized (1:1:1) to subcutaneous Taspo 10 mg QW (Taspo10), Taspo 10 mg QW for 4 wks titrated to 20 mg QW (Taspo20), or Exe 5 mcg BID for 4 wks titrated to 10 mcg BID. Primary outcome was HbA1c change at wk 24, testing for non-inferiority (NI) vs Exe (using 2-sided 95% CI for HbA1c difference and noninferiority margin of 0.4%) in the intent-to-treat (ITT) population. If NI was demonstrated, then statistical superiority was tested under closed test procedure.
Results: Baseline characteristics (56 yrs, 6.5 yrs T2DM, HbA1c 8.1%, BMI 33 kg/m^2) were similar across groups. At 24 wks in the ITT population, reductions in HbA1c and FPG with Taspo10 and Taspo20 were superior to Exe (Table). More patients on Taspo10 or Taspo20 achieved target HbA1c ≤7% than Exe: 64.8% (95% confidence interval [CI], 59.8-69.6), 67.9% (95% CI, 63.0-72.5), and 51.5% (95% CI, 46.3-56.7); respectively. Dose-dependent weight loss was seen with Taspo and weight loss with Taspo20 was similar to Exe (Table). Gastrointestinal (GI) complaints were the most frequently reported adverse events across all arms. Although they occurred with a higher incidence in the Taspo groups, discontinuation rate due to GI events was similar in the 3 arms.
Conclusion: Once-weekly Taspo provided superior glycemic control to Exe, with similar body weight reduction at the higher dose and comparable tolerability. (NCT00717457)

Retrospective cohort studies of the risk of acute pancreatitis: initiators of exenatide compared to other antidiabetic drugs in two commercial US health insurance claims databases

G. Bloomgren[1], M. Wenten[1], D. Dore[2], J. Seeger[2];
[1]Amylin Pharmaceuticals, Inc., San Diego, [2]i3 Drug Safety, Waltham, USA.

Background and aims: Cases of acute pancreatitis (AP) in patients treated with exenatide BID (Ex BID) have been reported.
Objective: To estimate the risk of AP in Ex BID initiators compared to initiators of other antidiabetic drugs (AD).
Materials and methods: Two retrospective studies were conducted to compare the rates of AP between patients without prior claims for pancreatic disease who initiated Ex BID or other AD (from 6/2005 to 12/2008) within 2 US commercial healthcare claims databases (Normative Health Information Database [NHI], Lifelink). The study protocols were similar to evaluate reproducibility of results. Both studies compared the risk of AP during periods of current, recent, or past exposure to Ex BID relative to other AD. AP cases were defined as patients with medical chart-confirmed acute pancreatitis (NHI) or claims for a hospitalisation associated with a primary diagnosis of AP (Lifelink). The NHI study used a multivariable Poisson regression model to estimate the AP propensity score adjusted rate ratios (RRs), and 95% confidence intervals (CIs) for current, recent, or past exposure. It included a blinded-medical record adjudication of claims-identified AP cases and a nested case-control study (NCCS) that involved conditional logistic regression modeling to obtain odds ratios (ORs) and 95% CIs adjusted for differences in the prevalence of risk factors between patients who persisted or discontinued the study drugs. The LifeLink study

analysis used discrete-time survival models to account for time-dependent exposure and inverse probability of treatment weighting to estimate ORs and 95% CIs for current, recent, or past Ex BID exposure accounting for measured risk factors.

Results: In both studies, Ex BID-treated patients were more likely to be female, obese, and had more evidence of diabetes complications than initiators of other AD. In the NHI database, there were 40 confirmed-AP cases in the Ex BID cohort (N=25,719), compared to 254 cases in the other AD cohort (N=234,536). In the LifeLink database, there were 46 AP cases in the Ex BID initiation cohort (N= 24,437) and 802 AP cases in the other AD cohort (N=457,797). In both analyses, current and recent Ex use periods were not associated with an increased risk of AP (Figure). For the past Ex BID use group in the NHI study, an increased risk of AP was observed, which was attenuated following NCCS adjustments for cholelithiasis, past AP, and obesity identified from the medical record review. However, in the LifeLink study, past Ex BID use was not associated with an increased risk.

Conclusion: Two studies using distinct analytic methods and data sets found Ex use was not associated with an increased risk of AP.

Effect of sitagliptin on glucose control in patients with type 1 diabetes - a pilot study

S.L. Ellis, E.G. Moser, J.K. Snell-Bergeon, R.S. Gutin, A.S. Rodionova, S.K. Garg;
Barbara Davis Center for Diabetes, University of Colorado Denver, Aurora, USA.

Background: Despite new therapies and technology, the average A1c in patients with type 1 diabetes (T1DM) remains well above ADA recommended targets. This investigator-initiated pilot study was designed to evaluate the effects of sitagliptin in poorly controlled (A1c 8.5-12%) patients with T1DM.

Methods: The study outcomes included area-under-the-curve for glucose excursions, A1c, and mean glucose values and other glycemic indices from CGM. Twenty patients were enrolled in this pilot randomized, double-blind, cross-over study to receive sitagliptin 100 mg daily or placebo for 1 month and then crossed over for 1 month. All patients used a blinded DexCom continuous glucose monitor (CGM) throughout the study period.

Results: There were no differences in baseline demographics between the two groups. Mean ± SD age and duration of diabetes were 32.5 ± 12.3 and 17.3 ± 7.5 years respectively. One patient was discontinued while on placebo for severe hypoglycemia. There was a significant reduction in insulin dose in subjects while on sitagliptin (p=0.02). Sitagliptin use reduced A1c values during both periods within groups. After controlling for period, treatment and insulin dose, there was a significant reduction in A1c in patients receiving sitagliptin (LSM = -0.27±0.11%; p=0.025; Figure). The CGM downloads showed a decrease in mean (± SE) blood glucose (-10.9 ± 3.8, p=0.012), J Index (-9.0 ± 3.1, p=0.010), High Blood Glucose Index (2.2 ± 0.70, p=0.007), M100 (-8.1 ± 2.7, p=0.009) and GRADE (-1.1 ± 0.4, p=0.023) when patients were receiving sitagliptin. Time spent in euglycemic range (80-140 mg/dl) was also significantly increased during sitagliptin use (0.46±0.20, p=0.046), while subjects trended to spending less time (hrs) in hyperglycemic range >240mg/dl (-0.55± 0.38, p=0.17).

Conclusions: We conclude that sitagliptin reduced total daily insulin dose, A1c and mean blood glucose values in patients with T1DM. Further research

Comparing ITCA 650, continuous subcutaneous delivery of exenatide via DUROS® device, vs. twice daily exenatide injections in metformin-treated type 2 diabetes

R.R. Henry[1], R. Cuddihy[2], J. Rosenstock[3], T. Alessi[4], K. Luskey[4];
[1]University of California, San Diego, La Jolla, [2]International Diabetes Center, Minneapolis, [3]Dallas Diabetes and Endocrine Center, Dallas, [4]Intarcia Therapeutics Inc., Hayward, USA.

Background and aims: ITCA 650 provides for the continuous and consistent delivery of exenatide using the DUROS technology, a subcutaneous osmotic delivery system that can deliver exenatide for up to 12 months with a single administration. This provides the opportunity to escalate to optimal doses of exenatide with good tolerability and ensure 100% patient compliance.

Materials and methods: A phase 2 study to evaluate the efficacy, safety and tolerability of ITCA 650 treatment with an introductory treatment dose during the initial 12 weeks and subsequent dose escalation is being conducted in subjects with inadequately controlled, metformin-treated type 2 diabetes (T2DM). In this study, subjects (n=50 /group) were initially randomized to receive either 20 or 40 mcg/day of exenatide delivered by ITCA 650 for 12 weeks or twice daily exenatide injections at 5 mcg BID for 4 weeks followed by 10 mcg BID for 8 weeks. Subsequently, subjects were randomized to receive ITCA 650 at 20, 40, 60 or 80 mcg/day for an additional 12 weeks.

Results: Treatment with ITCA 650 was well tolerated with less reported nausea at 20 mcg/day relative to exenatide injections. HbA1c was significantly lower after 12 weeks in all treatment groups (p<0.001 at week 12 relative to baseline). Weight was also reduced in all treatment groups. Dose escalation to ITCA 650 at the higher doses of 60-80 mcg/day resulted in further reductions in HbA1c at week 16 with a change of -1.3% (n=36) relative to baseline and continued weight loss.

Conclusion: ITCA 650 represents a novel and attractive treatment to deliver exenatide in a well-tolerated fashion that ensures 100% compliance for the long-term treatment of T2DM, resulting in substantial changes in HbA1c and weight without the need for repeated self injections. Escalation to higher doses leads to further reductions in HbA1c and weight in the long-term treatment of T2DM.

HbA1c and Weight Loss at Week 12

Dose Group	n	Baseline HbA1c	HbA1c at Week 12	Change in HbA1c at Week 12	HbA1c ≤7% at Week 12	n	Change in weight at Week 12
ITCA 650 20 mcg/day	36	7.9% ±0.8%	7.1% ±0.8%	-0.8% ±0.9%	58%	33	-0.5% ±2.5%

Fluctuation of haemoglobin A_{1c} is associated with higher incidence of cardiovascular disease in patients with type 2 diabetes

R. Bouchi, T. Babazono, M. Mugishima, N. Yoshida, I. Nyumura, K. Toya, T. Hayashi, K. Hanai, N. Tanaka, A. Ishii, Y. Iwamoto;
Division of Nephrology and Hypertension, Diabetes Center, Tokyo Women's Medical University, Japan.

Background and aims: Recent studies demonstrated that variability of hemoglobin A1C (HbA1C) may be associated with the risk of diabetic micro- and macrovascular complications in patients with type 1 diabetes; however, whether the similar association may exist in patients with type 2 diabetes is unclear. We, therefore, conducted this cohort study to highlight the relationship between the fluctuation of HbA1C and incident cardiovascular disease (CVD) in patients with type 2 diabetes.
Materials and methods: We studied 689 Japanese type 2 diabetic patients with an estimated glomerular filtration rate (eGFR) ≥ 15 mL/min/1.73 m^2, including 295 women and 394 men (mean [± SD] age: 65 ± 11 years). Patients were observed at least 12 months. Variability of HbA1C was defined as the intrapersonal SD of serially measured HbA1C during the whole follow-up period. Patients were divided into quartiles of SD HbA1C. The primary endpoint was defined as incident CVD including cerebral infarction and hemorrhage, myocardial infarction, and angina pectoris requiring coronary revascularization. Cox proportional hazard model was used to calculate hazard ratio and 95% confidence interval (95% CI). In the multivariate Cox regression analysis, the following variables were incorporated and selected by the stepwise procedure; age, sex, duration of diabetes, presence of proliferative diabetic retinopathy, smoking status, use of renin-angiotensin system inhibitors, antiplatelet agents and statins, hemoglobin, uric acid, eGFR, urinary albumin-to-creatinine ratio (ACR) at baseline, the mean of body mass index, systolic and diastolic blood pressures, triglycerides, high-density lipoprotein (HDL) and low-density lipoprotein (LDL) cholesterol levels during the follow-up period, and the mean, SD and number of measured HbA1C.
Results: During a median follow-up period of 3.3 years (range: 1.0 - 6.3 years, 2,279 patient-years), 26 ± 14 measurements of HbA1C were obtained per patient, and incident CVD episodes were observed in 61 patients (26.8 episodes per 1,000 patient-years). Patients with higher quartiles of SD HbA1C had a higher incidence of CVD; five-year cumulative incidence of CVD in patients with the first, second, third, and fourth quartile in order of increasing were 4.9, 8.7, 17.1, and 26.2%, respectively ($p < 0.001$ by the log-rank test). In the multivariate Cox analysis, the fourth quartile of SD HbA1C was associated with significantly higher incidence of CVD (hazard ratio 3.38, 95% CI 1.07 - 10.63) *versus* the first quartile, independently of the mean of HbA1C and traditional cardiovascular risk factors. Other significant covariates remained in the Cox model were age (hazard ratio 1.03, 95% CI 1.00 - 1.07), logarithmically transformed urinary ACR (hazard ratio 2.24, 95% CI 1.58 - 3.17, $p < 0.001$), and history of CVD (hazard ratio 2.34, 95% CI 1.32 - 4.16, $p = 0.004$).
Conclusion: Visit-to-visit variability of HbA1C may be a potent predictor of incident CVD, independent of mean HbA1C in Japanese patients with type 2 diabetes.

80

Significant association of TCF7L2 variant rs7903146 with angiographically characterised coronary artery disease in women

A. Muendlein[1,2], C.H. Saely[1,2], S. Geller-Rhomberg[1], G. Sonderegger[1], P. Rein[1,2], T. Winder[1,2], S. Beer[1,2], A. Vonbank[1,2], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Type 2 diabetes mellitus (T2DM) confers a particularly high risk of coronary artery disease (CAD) in women. Variations in the transcription factor 7-like 2 (TCF7L2) gene, particularly rs7903146, increase T2DM risk; their association with CAD is uncertain, no data are available for women. We therefore aimed at investigating potential links between TCF7L2 variant rs7903146 and CAD in women.

Materials and methods: We therefore investigated the association between rs7903146 and angiographically determined CAD in a cohort of 554 female Caucasian patients undergoing coronary angiography for the evaluation of established or suspected CAD. At angiography, significant CAD was diagnosed in the presence of significant coronary stenoses with lumen narrowing of ≥50%. The severity of CAD was calculated as the sum of all stenosis percentages of a given patient divided by the number of coronary stenoses in this patient and the extent as the number of significant coronary stenoses. The association between rs7903146 and CAD was evaluated in an additive genetic model.
Results: Variant rs7903146 was significantly associated with angiographically characterized CAD (additive odds ratio (OR)=1.37 [1.07-1.76]; p=0.011). Adjustment for age, smoking, BMI, total- and HDL-cholesterol did not significantly change this finding (OR)=1.37 [1.06-1.78]; p=0.016). Also, after further adjustment for T2DM, the association between rs7903146 and CAD remained significant (OR=1.31 [1.00-1.70]; p=0.047). Further, the extent of CAD significantly increased from subjects who were homozygous for the C allele over heterozygous subjects to those who carried the TT genotype (0.79±1.45, vs. 0.95±1.40 and 0.98±1.50, respectively; p=0.022). Similarly, a significant association between SNP rs7903146 and the severity of coronary lesions was observed (severity scores of 26.1±36.7, 35.7±39.9, and 36.7±39.4 for the CC, CT, and TT genotype, respectively; p=0.004).
Conclusion: We conclude that TCF7L2 variant rs7903146 is significantly associated with angiographically diagnosed CAD in women.

81

Trajectories of adiponectin before coronary heart disease (CHD): the Whitehall II prospective cohort study

M. Carstensen[1], C. Herder[1], M. Kivimäki[2], M. Jokela[2], M. Roden[1,3], M.J. Shipley[2], D.R. Witte[2,4], E.J. Brunner[2], A.G. Tabák[2,5];
[1]German Diabetes Center, Düsseldorf, Germany, [2]University College London, United Kingdom, [3]University Hospital Düsseldorf, Germany, [4]Steno Diabetes Center, Gentofte, Denmark, [5]Semmelweis University, Budapest, Hungary.

Background and aims: Adiponectin, an adipocyte-specific cytokine, is associated with reduced risk of type 2 diabetes, and it has anti-inflammatory, anti-thrombotic and anti-atherogenic properties. Although coronary heart disease (CHD) is a major complication of type 2 diabetes, high adiponectin levels have not been consistently linked to reduced CHD risk. One hypothesis is that the association between adiponectin and CHD varies as a function of the disease process over time. Thus, we took advantage of data from repeated measurements of adiponectin (i) to examine how serum adiponectin concentrations change during years preceding the manifestation of CHD and (ii) to compare these trajectories with those from individuals who did not develop CHD.
Materials and methods: This is a case-cohort analysis within the Whitehall II cohort with a total of 2778 participants without CHD at baseline, 26.9% women, mean age at baseline 49.3 (SD 5.9) years and average BMI 25.2 (SD 3.5) kg/m2. There were 284 incident cases of CHD (myocardial infarction, angina) during follow-up and 2494 non-cases who remained CHD-free. Serum adiponectin was measured at up to three time points for each participant (phase 3, the baseline: 1991-94; phase 5: 1997-99; phase 7: 2003-04). Year 0 of the observation period was the year of CHD diagnosis for cases and a randomly selected time point during follow-up for non-cases to approximate the follow-up time distribution of cases. Adiponectin levels were traced backwards up to participants' first adiponectin measurement. Multilevel models adjusted for age, sex and ethnicity were fitted to assess changes in adiponectin during the preceding 13 years based on 398 and 3871 serum samples in cases and non-cases, respectively.
Results: Serum adiponectin levels were 6% lower in cases [mean (95% CI), 8457 (8021; 8916) ng/ml] than in non-cases [8989 (8837; 9151) ng/ml] at study baseline. This difference remained constant during the follow-up in a model adjusted for age, sex and ethnicity (p=0.03) which means that it was independent of time until CHD diagnosis. The addition of nonlinear time terms for CHD cases did not improve the fit of the multilevel models, nor did these terms reach statistical significance. After adjustment for BMI or waist circumference as time-varying covariates, the slope of the linear upward adiponectin trajectories remained similar both among cases and non-cases, however the difference between the two groups was no longer statistically significant.
Conclusion: Adiponectin is mildly, but significantly lower in individuals who develop CHD throughout the 13 years preceding disease onset compared to those who remained CHD-free. BMI or waist circumference accounted for a substantial part of this difference, suggesting that adiponectin does not predict CHD independently of obesity. We found no support for the hypothesis that the association between adiponectin and CHD varies as a function of the disease process.

Vitamin D levels and asymptomatic coronary artery disease in type 2 diabetic patients with elevated urinary albumin excretion rate

C. Joergensen[1], H. Reinhard[1], A. Schmedes[2], P.R. Hansen[3], N. Wiinberg[4], C.L. Petersen[4], K. Winther[5], H.-H. Parving[6,7], P.K. Jacobsen[8,1], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, [2]Dept. of Clinical Biochemistry, Lillebaelt Hospital, Vejle, [3]Dept. of Cardiology, Gentofte University Hospital, [4]Dept. of Clinical Physiology and Nuclear Medicine, Frederiksberg University Hospital, [5]Dept. of Clinical Biochemistry, Frederiksberg University Hospital, Gentofte, [6]Dept. of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, [7]Faculty of Health Science, Aarhus University, [8]Copenhagen University Hospital, Rigshospitalet, Denmark.

Background and aims: Coronary artery disease (CAD) is the major cause of morbidity and mortality in type 2 diabetic patients. Severe vitamin D deficiency has been shown to predict cardiovascular mortality in type 2 diabetic patients. We investigated the association between severe vitamin D deficiency and asymptomatic CAD in type 2 diabetic patients with elevated urinary albumin excretion rate (UAER) > 30mg/24h. Furthermore, we evaluated the association between severe vitamin D deficiency and coronary calcium score (CCS).
Materials and methods: A cross sectional study including 200 type 2 diabetic patients without clinical signs of CAD. Plasma 25-hydroxy-vitamin D levels were determined by high performance liquid chromatography/tandem mass spectrometry. Severe vitamin D deficiency was defined as plasma 25-hydroxy-vitamin D < 12.5 nmol/l. Patients with plasma NT-proBNP > 45.2 ng/L and/or CCS > 400 were arbitrarily stratified as high risk patients for CAD (n = 129). High risk patients were examined by myocardial perfusion imaging (MPI; n = 109), and/or CT-angiography (CTA; n = 20), and/or coronary angiography (CAG; n = 86).
Results: Patients received mulitifactorial treatment, yielding mean (SD) HbA_{1c} 7.9 (1.3) %, plasma total cholesterol 3.9 (0.9) mmol/l and arterial blood pressure 130 (17)/75 (11) mmHg.
Median (range) vitamin D level was 36.9 (3.8-118.6) nmol/l. Vitamin D was not associated with sex, blood pressure, HbA_{1c} and UAER but a weak positive association was found with age (R = 0.159, p = 0.025). The prevalence of severe vitamin D deficiency was 9.5% (19/200). In 70 (35%) patients significant CAD was demonstrated by MPI and/or CAG. In a logistic regression model, severe vitamin D deficiency was associated with asymptomatic CAD, unadjusted odds ratio (OR [95% CI] 2.24 [0.87-5.81]; p = 0.097). After adjusting for additional risk factors (sex, age, plasma total cholesterol, plasma creatinine, distal systolic blood pressure at toe level, vibratory perception threshold, heart rate variability and plasma NT-proBNP), the OR was 5.00 [1.28-19.49]; p = 0.020. The prevalence of CCS > 400 was 34% (68/200). Severe vitamin D deficiency was significantly associated with CCS > 400 (unadjusted OR 4.32 [1.54-12.10]; p = 0.005). The association persisted after adjusting for all additional risk factors, (OR 3.98 [1.20-13.113]; p = 0.023). Moderate vitamin D deficiency, plasma 25-hydroxy-vitamin D: 12.5-25 nmol/l, and vitamin D insufficiency plasma 25-hydroxy-vitamin D: 25-50 nmol/l, were not significantly associated with increased presence of CAD or CCS > 400.
Conclusion: In high risk type 2 diabetes patients with elevated urinary albumin excretion rate, low levels of vitamin D are strongly and independently associated with asymptomatic coronary artery disease.

Prevalence and risk factors accounting for true silent myocardial ischaemia (clandestine ischaemia) in type 2 diabetic patients: a pilot case-control study

C. Hernández[1], J. Candell-Riera[2], A. Ciudin[3], S. Aguadé-Bruix[4], R. Simó[1];
[1]Diabetes and Metabolism Research Unit , CIBERDEM and RECAVA, Institut de Recerca Hospital Universitari Vall d'Hebron, [2]Cardiology Department and RECAVA, Hospital Universitari Vall d'Hebron, [3]Diabetes and Metabolism Research Unit, Institut de Recerca Hospital Universitari Vall d'Hebron, [4]Nuclear Medicine Department and RECAVA, Hospital Universitari Vall d'Hebron, Barcelona, Spain.

Background and aims: Given the elevated risk of cardiovascular events and the higher prevalence of silent coronary artery disease (CAD) in diabetic versus non-diabetic patients, the need to screen asymptomatic diabetic patients for CAD assumes increasing importance. The term of silent ischemia includes an entity named true silent myocardial ischemia or clandestine myocardial ischemia, which is characterized by myocardial perfusion defects in the absence of both angina and ST-segment depression > 1 mm during the exercise test. To the best of our knowledge there have been no studies addressed to determining its prevalence and the risk factors associated with its development. The aims of the study were to assess prospectively the prevalence and clinical predictors of true silent myocardial ischemia or clandestine ischemia in asymptomatic type 2 diabetic patients.
Material and methods: Stress myocardial perfusion gated-SPECT (Single Photon Emission Computed Tomography) was carried out in 41 type 2 diabetic patients without history of cardiovascular disease and 41 nondiabetic patients matched by age and gender. Left ventricular end-diastolic and end-systolic volumes, and ejection fraction were also measured in gated-SPECT. Exclusion criteria were: 1) history of cardiovascular disease (CVD); 2) electrocardiographic evidence of Q-wave myocardial infarction, ischemic ST depression, T-wave changes, or complete left bundle branch block; 3) flat or downsloping ST segment depression > 1 mm at 80 ms after the J-point during an exercise test on a bicycle ergometer.
Results: Apart from diabetes there were no significant differences between the two groups regarding either the classic CVD risk factors (age, gender, smoking habit, dyslipemia, hypertension, and family history of CAD) or left ventricular function. Clandestine ischemia was detected in 21.9% of type 2 diabetic patients but only in 2.4% of controls (p<0.01). The presence of myocardial perfusion defects did not correlate with the number of risk factors but was independently associated with male gender and the presence of diabetic retinopathy (DR). The probability of having myocardial perfusion defects in an asymptomatic diabetic patient with DR was 11.7 [IC95%: 3.7-37].
Conclusion: We conclude that clandestine ischemia is frequent in asymptomatic type 2 diabetic patients. In addition, DR is a high risk condition for true silent myocardial ischemia in asymptomatic type 2 diabetic patients, and point to these patients as a target to be screened for cardiovascular disease. Further prospective studies evaluating the prognostic value of these findings and their impact in economical terms are warranted.

Type 2 diabetes is not a coronary heart disease risk equivalent: results from an 8-year prospective cohort study on angiographically characterised coronary patients

T. Gansch[1], C.H. Saely[1,2], A. Vonbank[1,2], P. Rein[1,2], S. Beer[1,2], S. Greber[1], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Current guidelines consider diabetes as a coronary artery disease (CAD) risk equivalent, but cardiovascular risk in patients with diabetes may vary substantially depending on the presence of subclinical CAD at baseline. In the present study we therefore aimed at investigating the contribution of baseline coronary atherosclerosis to the risk of future vascular events in patients with diabetes.
Materials and methods: Vascular events were recorded over 8 years in 750 consecutive patients undergoing coronary angiography for the evaluation of established or suspected stable CAD.
Results: From our patients, 244 had neither type 2 diabetes (T2DM) nor significant CAD (i.e. coronary stenoses ≥50%) at the baseline angiography, 50 had T2DM but not significant CAD, 342 did not have T2DM but had significant CAD, and 114 had both T2DM and significant CAD. Non-diabetic subjects without significant CAD had an event rate of 20.5%. The event rate was similar in T2DM patients without significant CAD (22.0%; p = 0.811), but higher in non-diabetic patients with significant CAD (39.5%, p <0.001). Patients with T2DM plus significant CAD had the highest event rate (53.5%; p <0.001). Importantly, T2DM patients without significant CAD had a significantly lower event rate than non-diabetic patients with significant CAD (p = 0.017).
Conclusion: T2DM *per se* is not a CAD risk equivalent. Moderate risk diabetic patients without significant CAD and very high-risk diabetic patients with significant CAD add up to a grand total of high risk diabetic patients: this is why diabetes appears as a CAD risk equivalent in many epidemiological studies.

Long-term prevention of mortality in morbid obesity through bariatric surgery. A systematic review and meta-analysis of trials performed with gastric banding and gastric bypass

A. Morabito[1], A.E. Pontiroli[1,2];
[1]Dipartimento di Medicina, Chirurgia e Odontoiatria, Università degli studi di Milano, [2]Dipartimento di Medicina, Ospedale San Paolo, Milano, Italy.

Background: Bariatric surgery has been reported to reduce long-term mortality in comparison with non-operated subjects, but there are no studies comparing gastric banding and gastric by-pass.
Methods: We performed a systematic review and meta-analysis of clinical trials published as full papers dealing with all-cause mortality, cardiovascular mortality, and global mortality (sum of all-cause and cardiovascular mortality). Pooled-random effects of estimates of the risk of mortality in subjects undergoing surgery, compared with controls, were calculated using the Der Simonian and Laird models.
Results: Of 44,022 participants from eight trials, death occurred in 3,317 subjects (400 in surgery, 2,917 in controls); when the kind of death was specified, 321 cardiovascular deaths (118 in surgery, 203 in controls), and 523 all-cause deaths (218 in surgery, 305 in controls) occurred. Compared with controls, surgery was associated with a reduced risk of global mortality (OR = 0.27, 95% C.I. 0.16-0.45), of cardiovascular mortality (OR = 0.43, C.I. 0.24-0.77), and of all-cause mortality (OR = 0.60, C.I. 0.37-0.97). Data of all-cause mortality were not heterogeneous; heterogeneity of data of cardiovascular mortality and of global mortality disappeared when studies were grouped according to size (larger vs smaller studies). At meta-regression analysis, decrease of global mortality (Log OR) was significantly associated with increasing BMI ($p = 0.036$). The effect of gastric banding and gastric by-pass (3,797 vs 10,255 interventions) was not significantly different for the any kind of mortality.
Conclusion: This meta-analysis indicates that: 1) bariatric surgery reduces all-cause, cardiovascular, and global mortality; 2) there are no significant differences between gastric banding and gastric by-pass; 3) the effect is more evident for greater BMI.

86

Weight loss modulates DNA methylation of peroxisome proliferator-activated receptor gamma coactivator-1 and pyruvate dehydrogenase kinase, isozyme 4 promoters

J. Yan[1], R. Barrès[1], A. Krook[1], E. Näslund[2], J.R. Zierath[1];
[1]Karolinska Institutet, [2]Department of Clinical Sciences, Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Obesity is associated with reduced insulin sensitivity and extensive changes in skeletal muscle. When diet and drugs no longer work, many morbidly obese individuals opt to undergo bariatric surgery as a means to reduce body mass. DNA methylation is believed to be modulated by the environment and can act as a reversible switch of gene expression that can lock genes in an active or repressed state. We determined whether DNA methylation of select proteins is altered in obesity and after weight loss.
Materials and methods: DNA methylation level of the Peroxisome Proliferator-Activated Receptor γ Coactivator-1 α (PGC-1α) and Pyruvate Dehydrogenase Kinase, isozyme 4 (PDK4) promoters was investigated in vastus lateralis skeletal muscle from eight non-diabetic obese people (41.8 ± 3.7 years) before (BMI 42.1 ± 1.5 kg/m^2) and six months after gastric bypass surgery (BMI 31.2 ± 1.6 kg/m^2).
Results: Plasma concentrations of glucose and insulin were reduced 6 months after weight loss surgery (5.6 ± 0.3 vs 4.8 ± 0.2 mmol/L and 99.9 ± 19.8 vs 56.6 ± 8.4 pmol/L, glucose and insulin, respectively). Levels of inflammatory cytokines such as C-reaction protein (CRP) and monocyte chemoattractant protein-1 (MCP-1) were markedly decreased after weight loss surgery. Weight loss induced hypomethylation of the PGC-1α promoter and hypermethylation of the PDK4 promoter as examined by bisulfite DNA methylation analysis. These changes in DNA methylation levels were inversely correlated with mRNA expression of PGC-1α and PDK4. To determine whether systemic factors associated with insulin resistance and obesity influence promoter methylation, we incubated primary human skeletal muscle cultures for 48 hours with tumor necrosis factor-α (TNF- α). In vitro exposure of muscle cells triggered hypermethylation of the PGC-1α promoter and hypomethylation of the PDK4 promoter.
Conclusion: The dynamic regulation of PGC-1α and PDK4 promoter methylation with obesity and after weight loss surgery appears to contribute to the regulation of mRNA expression and metabolism. Our results further suggest that environmental factors acutely alter the methylation status of promoters regulating glucose and lipid metabolism in skeletal muscle. DNA methylation in somatic cells appears to be a more dynamic process than previously thought.

87

Assessment of insulin secretion and insulin sensitivity with the hyperglycaemic clamp in type 2 diabetic patients with BMI below 35 Kg/m^2 submitted to ileal interposition associated to sleeve gastrectomy

S.A.C. Vencio[1], A.R. Stival[2], A.L. De Paula[2];
[1]Endocrinology, Hospital de Especialidades, [2]Metabolic Surgery, Hospital de Especialidades, Goiania, Brazil.

Background and aims: Type 2 diabetes is a progressive disease. Beta cell failure is related to the reduction in insulin secretion and associated with some complications of the disease. Laparoscopic ileal interposition associated with sleeve gastrectomy (II-SG) had demonstrated a positive effect in insulin resistance. We used the hyperglycemic clamp, the gold standard method for measurement of insulin secretion to assess the impact of this operation on beta cell function.
Materials and methods: A 3-hour hyperglycemic clamp was performed in 35 patients preoperatively and in 33 patients postoperatively. To calculate the first phase insulin secretion (1st phase), an intravenous glucose load was made at the beginning. In the 170 minutes remaining, glucose was kept 125 mg / dl above basal glucose, in order to calculate the second phase insulin secretion (2nd phase). Mean age was 55 years (range 34-69 years). Mean diabetes duration was 12.3 years (5-24 years). Mean follow-up was 20 months (range 8-38 months).
Results: Postoperatively, BMI decreased from 29.5 +-5.2 Kg/m^2 to 22.1 +- 2.4 Kg/m^2. Mean plasma glucose was 259 mg/dl in preoperative and 239 mg/dl in postoperative period. Insulin sensitivity increased from 69.4 mmol.min^{-1}.nmol^{-1} to 95.5 mmol.min^{-1}.nmol^{-1}. In the 1st phase, the acute C-peptide response was 2219 +- 2268 pmol.l^{-1} .10min and increased to 2617 +- 2164 pmol.l^{-1} .10min. The relation of incremental C-peptide area under the curve and incremental glucose area under the curve, increased from 30 +- 24 pmol.mmol-1 to 46 +- 30 pmol.mmol-1. The evaluation of the 2nd phase by the insulin incremental area and insulin sensitivity was 688 x 10^4 pmol.mmol.nmol^{-1} and increased to 811 x 10^4 pmol.mmol.nmol^{-1} postoperatively.
Conclusion: In non morbidly obese type 2 diabetic patients ileal interposition associated with sleeve gastrectomy showed an important improvement in insulin secretion after a mean follow-up of 20 months as demonstrated by the hyperglycemic clamp.

88

The role of apolipoprotein A5 in non-alcoholic fatty liver disease

C. Ress[1], A. Moschen[2], A. Tschoner[1], C. Ciardi[1], C.F. Ebenbichler[1], J.R. Patsch[1], H. Tilg[2], S. Kaser[1];
[1]Department of Medicine 1, [2]Department of Medicine 2, Medical University Innsbruck, Austria.

Background and aims: The term non-alcoholic fatty liver disease (NAFLD) comprises a wide spectrum of clinical entities ranging from simple steatosis, steatohepatitis to fibrosis and cirrhosis. NAFLD is strongly associated with obesity and is found in up to 91% of severe obese patients undergoing bariatric surgery. Apolipoprotein (apo) A5 is a recently discovered protein synthesized by the liver that plays a major role in triglyceride metabolism. In mice, overexpression of apoA5 leads to dramatically decreased plasma triglyceride levels. Mechanistically, extracellular effects by activating lipoprotein lipase and intracellular effects have been proposed. In this study we aimed to investigate a possible role of apoA5 in NAFLD.
Materials and methods: Hepatic apoA5 mRNA expression was determined in 15 severely obese subjects with histologically proven NAFLD before and after pronounced weight loss due to bariatric surgery. Hepatic apoA5 mRNA expression was estimated by fluorescence-based real time polymerase chain reaction. Effects of apoA5 on hepatic triglyceride accumulation were investigated in apoA5 deficient HepG2 cells due to transfection with apoA5 siRNA.
Results: Mean weight loss of 18 kg was accompanied by improved insulin sensitivity as estimated by the HOMA index and improvements in hepatic steatosis. In parallel, hepatic apoA5 mRNA expression was decreased by 41 % ($p=0.017$). Transfection of apoA5 siRNA in HepG2 led to a mean reduction

of 83 % in apoA5 mRNA expression (p=0.001), as determined by fluorescence-based real time PCR. Suppression of apoA5 in HepG2 cells resulted in a reduction of intracellular triglyceride content by 31 % (p<0.001), when compared to controls transfected with nonsilencing siRNA.
Conclusion: In summary, we found that pronounced weight loss in obese subjects with NAFLD results in a significant improvement of hepatic steatosis which is associated with a decline of hepatic apoA5 mRNA levels. Our in vitro data suggest that weight loss induced reduction in hepatic apoA5 mRNA expression is not an epiphenomenon but has a causal role in improvement of NAFLD in morbid obesity.

Can diabetes and obesity be treated through the rectum?
T.E. Adrian[1], S. Gariballa[2], K.A. Parekh[1], S.A. Thomas[1], H. Saadi[2], J. Al Kaabi[2], N. Nagelkerke[3], B.R. Gedulin[4], A.A. Young[4];
[1]Physiology, UAE University, [2]Internal Medicine, UAE University, [3]Community Medicine, UAE University, Al Ain, United Arab Emirates, [4]Satiogen Pharmaceuticals Inc, San Diego, USA.

Background and aims: The enteroendocrine L cells produce glucagon gene products including GLP-1 and oxyntomodulin which are satiety factors and the former is an insulin secretagogue. The L-cells also produce PYY, the major molecular form of which is also a satiety factor. The number of L-cells and hormonal contents increase distally through the gut with highest concentrations in the rectum. We have previously shown that intracolonic infusion of bile salts in humans causes secretion of L-cell hormones, triggered via TGR5 membrane receptors. The present study was designed to investigate the dose-responsive effects of intrarectal taurocholic acid (TA) on circulating concentrations of GLP-1, PYY, insulin, glucose and on food intake of a subsequent meal.
Materials and methods: Ten obese type 2 diabetic subjects were each studied on five separate occasions after an overnight fast and administration of 100 mg oral sitagliptin10 hours before the study. They then received an intrarectal infusion of either one of four amounts of TA (0.66, 2, 6.66, or 20 mmoles) or vehicle placebo in a random blinded fashion. Bile salts were administered in 20 ml of a 1% carboxymethyl cellulose emulsion over 1 min. Hormone and glucose measurement was made in plasma samples were collected for one hour following the infusion. 75 mins after the infusion, the subjects were presented with an unlimited amount of a previously selected favorite meal and invited to eat until satisfied.
Results: TA caused a dose-responsive increase of GLP-1, PYY and insulin, with peak concentrations ~ 7-fold, 4-fold and 3-fold increased, respectively with 20 moles TA (all P<.0001). There was a corresponding decrease in circulating glucose concentrations (P< 0.0001), with a decrease in glucose of ~2.8 mmol/L with 20 moles TA. The TA infusions were also associated with a decrease in caloric consumption of the subsequent meal (P<0.0001), with a maximal inhibition of 45±6 % with 20 mmoles TA.
Conclusion: Intrarectal TA increased L cell secretion which markedly decreased food intake and, since the subjects had fasting hyperglycemia, this resulted in an incretin effect. These findings probably explain the glucose-lowering effects of bile salt sequestrants. Intrarectal TGR5 agonists are likely to be valuable in the treatment of type 2 diabetes and obesity.

Metabolic effects of transplanting gut microbiota from lean donors to subjects with metabolic syndrome
A. Vrieze[1], F. Holleman[1], M.J. Serlie[2], M.T. Ackermans[2], G.M. Dallinga-Thie[1], A.K. Groen[3], E. van Nood[1], J.F.W. Bartelsman[4], R. Oozeer[5], E. Zoetendal[6], W.M. de Vos[6,7], J.B.L. Hoekstra[1], M. Nieuwdorp[1];
[1]Department of Internal and Vascular Medicine, [2]Department of Endocrinology and Metabolism, Academic Medical Centre, Amsterdam, [3]Center for Liver, Digestive, and Metabolic Diseases, University Medical Center Groningen, [4]Department of Gastroenterology, Academic Medical Centre, Amsterdam, Netherlands, [5]Danone Research Center, Paris, France, [6]Laboratory of Microbiology, Wageningen University, Netherlands, [7]Department of Veterinary Biosciences, University of Helsinki, Finland.

Background: Recent data in animal models revealed that obesity is associated with substantial changes in composition and metabolic function of gut microbiota. Moreover, colonization of germ-free mice with faeces harvested from obese mice resulted in a significantly greater increase in total body fat than colonization with a 'lean microbiota'. However, data on the role of gut-microbiota in human obesity are scarce. Thus, our aim was to examine the effect of faecal infusions derived from lean healthy donors on gut microbiota composition, glucose and lipids in metabolic syndrome.
Methods: This study was a double-blind, randomised controlled trial. A total of 18 male subjects with newly diagnosed metabolic syndrome (BMI≥30 kg/m2, FPG>5.6mmol/L, TG>1,6 mmol/L with no medication use) underwent jejunum biopsies and subsequent polyethylene-glycol bowel lavage through duodenal tube followed by random assignment to either allogenic (from lean male donors with BMI<23 kg/m2, n=9) or autologous faecal transplantation (reinfusion of own collected faeces, n=9). We studied changes in sigmoidal microbiota composition and fasting lipidprofiles at 0.5, 2, 6 and 12 weeks after faecal transplantation. Weight, jejunal gut microbiota (epithelial biopsy) and glucose metabolism (peripheral and hepatic insulin sensitivity as assessed by hyperinsulinemic euglycemic clamp with stable isotopes) were studied before and 6 weeks after transplantation.
Results: Lean subjects were characterized by different sigmoidal gutmicrobiota compared to obese subjects (by HITChip phylogenetic microarray analysis). Fasting levels of TG-rich lipoproteins (TG/ApoB ratio) were significantly reduced following donor faeces (1.43 ± 0.21 to 1.11 ± 0.18, p<0.01) with no effect after autologous faeces infusion. REE and basal endogenous glucose production (EGP) did not change in both groups after faecal infusion. Although weight remained stable, an improvement in both peripheral (Rd) and hepatic insulin sensitivity (suppression of EGP) was found 6 weeks after allogenic faeces (median Rd: from 26.2 to 45.3 µmol/kg.min, p=0.02 and EGP suppression: from 51.5 to 61.6 %, p=0.08) while no significant changes were observed in the autologous treatment group (Rd: from 21.0 to 19.5 µmol/kg.min and EGP suppression:from 53.8 to 52.4 %, ns). Changes in jejunal microbiota are currently analyzed.
Conclusion: Lean donor faecal infusion improves hepatic and peripheral insulin resistance as well as fasting lipid levels in obese individuals with the metabolic syndrome underscoring the potential role of gut microbiota in the disturbances of glucose and lipid metabolism in obesity. Our data could provide pathophysiological insight in the metabolic deviations in obese subjects and a rationale for therapeutic intervention.

OP 16 Mechanisms of insulin secretion

91

The role of wnt antagonists in impaired beta cell exocytosis

T. Hamed, A. Salehi, E. Renström, A.H. Rosengren;
Lund University Diabetes Centre, Malmo, Sweden.

Background and aims: We have recently found that genetically encoded overexpression of ADRA2A (the alpha2A-adrenergic receptor) contributes to impaired insulin secretion in type 2 diabetes (T2D). The aim here is to get a more overall view of the adrenergic signaling system and linked molecular pathways in defective insulin release. Network methods have proven valuable for studying how cellular pathways cause disease and have been successfully applied to e.g. obesity. However, in the case of T2D little is known about the networks that drive the pathogenesis.
Materials and methods: We have used linear algebraic methods to analyze the topological overlap in microarray data from human islets and performed subsequent cluster analysis. Highly connected hub genes play an important role in networks, and hub gene validation has been conducted by insulin secretion assays and patch-clamp recordings of exocytosis.
Results: We have characterized the gene expression networks in human islets and identified a subnetwork with 120 genes connected to ADRA2A. The expression of this subnetwork was associated with reduced insulin secretion ($p=0.008$), elevated HbA1c ($p=0.0002$) and T2D ($p=0.00006$) in the islet donors. Of the top 100 genes for which the expression was correlated with T2D in the microarray, as many as 53 belonged to the identified ADRA2A-related network (enrichment p value is 8e-189). One of the most highly connected hub genes of the ADRA2A subnetwork is a secreted frizzled-related protein (sfrp), which is an extracellular antagonist of the wnt system. Interestingly, TCF7L2, the strongest T2D gene known, is regulated by the wnt system. The role of sfrp in T2D has not been studied previously. Our data show that activation of the wnt system by wnt7a stimulated insulin secretion both during a 21 hour incubation at low glucose (5 mM) and when glucose thereafter was elevated to 16.7 mM (see Figure). Interestingly, sfrp has previously been shown to co-precipitate with wnt7a in neuron studies, and the addition of sfrp completely antagonized the stimulatory effect of wnt7a in islets ($p<0.05$). These findings were paralleled on the single-cell level. Beta-cell exocytosis increased from 12.5±2.2 fF/pF to 20.6±3.3 fF/pF ($p=0.045$) by pre-treatment with 400 ng/ml wnt7a. The stimulatory effect of wnt7a was abolished by the addition of 100 nM sfrp (10.2±4.1 fF/pF). Sfrp also had an inhibitory effect on its own and reduced exocytosis to 5.9±1.4 fF/pF ($p=0.013$ vs. control, and $p=0.0002$ vs. wnt7a).
Conclusion: We have characterized the gene expression networks in human islets and identified an ADRA2A-related subnetwork that is associated with T2D. One of the subnetwork hub genes, sfrp, reduced insulin secretion and beta-cell exocytosis when applied alone or in combination with wnt activators. This validates the importance of the identified subnetwork in T2D and illuminates an extracellular player that could affect insulin secretion through the TCF7L2 pathway.

Resveratrol potentiates glucose-stimulated insulin secretion in INS-1E cells and human islets through SIRT1 dependent mechanism

L. Vetterli[1], J. Rodgers[2], D. Bosco[3], P. Puigserver[2], P. Maechler[1];
[1]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland, [2]Department of Cancer Biology, Harvard Medical School, Boston, USA, [3]Department of Surgery, University of Geneva, Switzerland.

Background and aims: Sirtuins are energy sensors which mediate effects of calorie restriction-induced lifespan extension. SIRT1, one of the mammalian Sirtuin homolog, is a transcription factor that deacetylates specific substrates. Previous studies have shown that SIRT1 is implicated in glucose metabolism and beta-cell function. Here, we investigated the role of SIRT1 through the activating action of resveratrol on insulin secretion. Resveratrol is a polyphenol found in red grapes and wine that has been demonstrated to increase lifespan and to protect mice against high-fat diet induced obesity and insulin resistance.
Materials and methods: Chronic (24h) treatment with 25 μM resveratrol was tested on insulinoma INS-1E cells and effects on insulin secretion, gene expression (qRT-PCR), and metabolic parameters were measured (ATP production, glucose oxidation and utilization, oxygen consumption). We then tested resveratrol treatment in cells over-expressing SIRT1 or expressing inactive mutant SIRT1 after adenoviral transduction, as well as pharmacological SIRT1 inhibitor (1 μM EX-527). Chronic effects of resveratrol on insulin secretion and gene expression were also studied in human islets.
Results: Chronic treatment of INS-1E cells with 25 μM resveratrol resulted in marked potentiation of insulin secretion at 15 mM glucose (+114%, $p<0.01$). This effect was associated with enhanced metabolism since glucose utilization was increased by +32% ($p<0.01$), resulting in elevated glucose oxidation, ATP generation, and mitochondrial oxygen consumption. Such changes correlated with up-regulation of key genes for beta-cell function and differentiation, i.e. glucose transporter GLUT2 (+59%), glucokinase (+89%), Pdx-1 (+70%), and TFAM (+232%). In human islets, chronic resveratrol treatment also significantly increased glucose-stimulated insulin secretion and induced expression of the same set of genes. Over-expression of SIRT1 in INS-1E cells potentiated resveratrol effects on insulin secretion. Conversely, inhibition of SIRT1 achieved either by expression of a mutant that lacks deacetylase activity or alternatively by using the EX-527 inhibitor, both abolished resveratrol effects on glucose-stimulated insulin secretion. Chronic treatment of INS-1E cells with EX-527 also prevented up-regulation of GLUT2, glucokinase, Pdx-1, and TFAM, normally induced by resveratrol.
Conclusion: Treatment of beta-cells with resveratrol markedly enhanced glucose-induced insulin secretion in INS-1E cells and human islets, even after removal of the compound from the medium. Data show that resveratrol effects were mediated by SIRT1 activation, defining a new role for SIRT1 in the regulation of insulin secretion.

Melatonin effects on insulin secretion and clock genes expression

J.A. Stamenkovic[1], C.L.F. Nagorny[1], C. Ling[2], A. Salehi[3], V.V. Sharoyko[1], H. Mulder[1];
[1]Clinical Sciences Malmö; Molecular Metabolism, Lund University, Malmoe, [2]Clinical Sciences Malmö; Diabetes and Endocrinology, Lund University, Malmoe, [3]Clinical Sciences Malmö; Islet Cell Physiology, Lund University, Malmoe, Sweden.

Background and aims: Melatonin is rhythmically released by the pineal gland and thus represents an important regulator of seasonal and circadian rhythms. Both melatonin receptors MTNR1A and MTNR1B are expressed in INS-1 cells and in rat and human islets (primarily in alpha cells). Genome-wide association studies have identified a SNP, rs10830963, in *MTNR1B* that is associated with elevated fasting plasma glucose levels, impaired insulin secretion and T2D. Previously, peripheral circadian rhythms in heart, liver and pancreas have been shown and that these rhythms are independent from the central clock located in the suprachiasmatic nucleus (SCN). Given the association of *MTNR1B* with T2D and insulin secretion, we aimed to resolve whether the effects of melatonin on β-cells could be mediated by entrainment of circadian rhythm.
Materials and methods: Expression of mRNA for Clock genes in human islets and clonal β-cells (INS-1 832/13 cells) was determined by microarray (Affymetrix) or RT-PCR, respectively. To determine the effects of melatonin on insulin secretion, we incubated human islets and clonal β-cells at 2.8 and 16.7 mM glucose with or without 0.1 μM melatonin for 1 h. Released insulin was determined by radioimmunoassay.
Results: Microarray analysis of human islets showed that Clock, Per1-3, and Cry 1-2 were expressed. Moreover, while MTNR1A expression correlated positively with Per1 (rho=0.037; p=0.04), MTNR1B expression correlated negatively with Cry1 (rho=-0.41; p=0.02) in the human islets. RT-PCR confirmed mRNA expression of the melatonin receptors MTNR1A and MTNR1B in INS-1 832/13 cells. In addition, mRNA expression of the clock genes CLOCK and PER1 were detected in INS-1 832/13 cells. Insulin from 832/13 cells increased 6.92-fold in response to16.7 mM glucose (69.65 ± 9.11 insulin ng/mg protein/h) compared to secretion at 2.8 mM glucose (10.07 ± 2.35 insulin ng/mg protein/h). The stimulation of the INS-1 832/13 cells with glucose + melatonin resulted in decreased GSIS (4.57 fold; p=0.02) at 16.7 mM glucose (36.54 ± 8.72 insulin ng/mg protein/h). Insulin from human islets, from 4 different donors, decreased 2-fold (p=0.06) in response to 16.7 mM glucose + melatonin (0.79 ± 0.17 insulin ng /islet /h) compared to secretion at 16.7 mM glucose (1.34 ± 0.18 insulin ng /islet /h).
Conclusion: Our data demonstrate the existence of components of the molecular clock in human islets and clonal β-cells. In addition, melatonin exerted an inhibitory effect on insulin secretion provoked by high glucose. Given that islets and β-cells express CLOCK genes and are sensitive to melatonin, there is a possibility that melatonin may entrain circadian rhythm. This agrees with previous suggestions that insulin displays a diurnal pattern.

Quantitative analysis of t-SNARE and Ca2+-channel clusters near secretory granules

S. Barg, N. Gandasi;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: For insulin to be secreted from pancreatic -cells, secretory granules must translocate to and then dock at the plasma membrane. Secretagogues can then trigger exocytosis of these granules, resulting in release of insulin. Only a limited number of granules can dock at any time, suggesting the existence of specialized docking sites where the exocytosis machinery is assembled. This is supported by the finding that the t-SNARE syntaxin 1a (syx), an integral plasma membrane protein which is required for docking and exocytosis, clusters in raft-like nanodomains near docked granules. The function of these clusters is unknown, but it seems likely that they contain other t-SNARE and regulatory proteins, which together act as acceptor complex for the docking granule. Moreover, there is indirect evidence suggesting that clusters of L-type Ca2+-channels (CaV1.2) are required near the granule for rapid exocytosis; ablation of the gene encoding Cav1.2 abolishes 1st phase insulin secretion and results in systemic glucose intolerance. The channel associates in biochemical assays with t-SNAREs. Here we have quantified the dynamic interaction of syx and CaV1.2 clusters with secretory granules during docking and exocytosis.
Materials and methods: Dual-color TIRF microscopy and novel quantitative image analysis was used to study the association of GFP-labeled syx and Cav1.2 with granules at the plasma membrane of live Ins1- and PC12 cells. Granules were labeled with NPY-cherry as spatial reference. Single molecule imaging and PALM super-resolution microscopy were done on the same instrument to measure protein diffusion and cluster size.
Results: Syx and CaV1.2 formed small clusters (<100 nm) in the plasma membrane that contained about 70 molecules of syntaxin and associated with a subset of the docked granules (30-50%). Granules near such a cluster were more likely to undergo exocytosis during stimulation. Clusters were stable on a minute scale and moved no faster than docked granules. In contrast, the number of syx molecules fluctuated on a second scale and individual molecules of both proteins diffused rapidly in the plasma membrane. When observed at the single molecule level, individual copies of syx and Cav1.2 were captured beneath docked granules, for a short time (<1s). Syx was recruited to the granule site during docking, and lost during undocking and exocytosis. A syx mutant lacking the N-terminus formed clusters that were excluded from granules, while a mutation in the SNARE domain had little effect.
Conclusion: In summary, the protein composition of individual granule-associated nanodomains is remarkably dynamic and correlates with the granules' ability to exocytose. This organization is established during or just after granule docking, which suggests that granules approaching the plasma membrane might induce the formation of their own docking site. Dynamic association of exocytosis proteins with individual granules occurs on a timescale consistent with rapid cellular signaling, and may be important for the short-term regulation of insulin secretion.

CART is upregulated in islets of type 2 diabetic patients, stimulates insulin secretion, inhibits glucagon secretion and protects against beta cell death

R. Sathanoori[1], U. Voss[1], M. Riva[1], M.S. Winzell[1], B. Ahrén[1], O. Korsgren[2], N. Wierup[1];
[1]Lund University Diabetes Centre, Lund University, [2]Department of Clinical Immunology, Uppsala University, Sweden.

Background and aims: Cocaine- and amphetamine-regulated transcript (CART) is a regulatory peptide expressed in the islets of many laboratory animal species. CART KO mice exhibit impaired glucose tolerance due to islet dysfunction, and CART has been shown to regulate insulin secretion from rat islets and clonal beta cells. Furthermore, CART is upregulated in rodent models of type 2 diabetes (T2D). We examined CART expression in human islets from T2D patients and control subjects. Furthermore, we studied the effect of CART on beta cell survival, as well as the effect of CART on insulin and glucagon secretion in vivo and in vitro in mice. We have previously shown that CART exerts its effect on insulin secretion in part via increased cAMP and PKA-dependent pathways. In this study we investigated potential effects of CART on Ca2+ signaling.
Materials and methods: CART expression was examined using immunocytochemistry, in situ hybridization. IVGTT with i.v. administration of CART was performed in anesthetized C57Bl6 mice. Insulin and glucagon secretion after 1h static incubations of isolated mouse islets was analyzed with RIA or ELISA. Ca2+ fluorescence and glucotoxicity was assessed in INS-1 (832/13) cells.
Results: CART mRNA and protein expression was evident in human alpha and beta cells as well as in intra-pancreatic nerve fibers innervating the islets. T2D islets displayed 3-fold higher CART mRNA levels than controls. In addition, the number of CART-expressing alpha and beta cells was 2.5-fold higher in type 2 diabetic patients, as compared to control subjects. Intravenous CART administration improved glucose-elimination and increased glucose stimulated insulin secretion (GSIS) after an IVGTT in mice. CART increased insulin secretion from isolated mouse islets stimulated with glucose, GLP-1, and palmitate. On the other hand, CART had no effect on insulin secretion in the presence of KCl, alpha-KIC or carbachol. CART increased cytoplasmic Ca2+ concentration in INS-1 (832/13) cells in a dose-dependent fashion at both high and low glucose concentrations. The effect was still evident when Ca2+ was absent in the assay buffer, suggesting that Ca2+ is mobilized from internal stores. The effect of CART was sustained after prior exposure to pertussis toxin, suggesting that CART does not act via Gi/o coupled receptors. In addition, CART reduced secretion of glucagon from isolated mouse islets at both low and high glucose concentrations. Furthermore, addition of ex-

ogenous CART resulted in a 50% decrease in glucose-induced cell death in INS-1 (832/13) cells.
Conclusion: We conclude that CART 1) is expressed in human islet cells and nerve fibers. 2) is upregulated in the islets of type 2 diabetic subjects. 3) improves glucose elimination and stimulates insulin secretion in vivo and in vitro. 4) inhibits glucagon secretion. 5) exerts a cytoprotective effect on beta cells. Together these data suggest that CART is upregulated in human T2D islets to protect the islets against glucotoxicity and to lower plasma glucose.

Dysfunctions of neuronal NO synthase in pancreatic beta cells from human islets issued from obese subjects
A. Chalançon, F. Castex, K. Mezghenna, P. Petit, R. Gross, A.-D. Lajoix;
Faculte de Pharmacie, CNRS UMR 5232, Montpellier, France.

Background and aims: We have previously shown that rat pancreatic β-cells express an isoform of neuronal NO synthase (nNOS), that controls insulin secretion through two catalytic activities: NO production and cytochrome c reduction. We also found functional and molecular abnormalities of nNOS, involved in pancreatic β-cell hyperactivity in an animal model of prediabetic state, the Zucker fa/fa rat. In the present study, we investigate whether, as observed in rats, nNOS dysfunctions could also occur in islets from obese subjects.
Materials and methods: Human islets from normal-weight or obese subjects were obtained from brain dead donors in the frame of a transplantation protocol of Gragil network. nNOS expression was studied by RT-PCR and Western Blot, its subcellular localization by confocal microscopy. Insulin secretion in response to glucose (2.8, 8.3, and 16.7 mM) was evaluated on pools of 10 islets during 90 minutes in the presence or not of a pharmacological inhibitor of nNOS, Nω-nitro-L-arginine methyl ester (L-NAME).
Results: We found that nNOS is expressed in human β-cells and, as previously observed in rats, co-locates with insulin secretory granules. In islets from obese subjects, nNOS is overexpressed and co-locates more strongly with insulin granules as compared to islets from normal-weight subjects. Moreover, islets from obese subjects were found more sensitive to glucose, as previously observed in fa/fat rats: at 2.8 mM glucose, insulin secretion reached 19.4 ± 2.05 (n = 2), versus 10.09 ± 0.8 ng/ml/10 islets/90 min ($p < 0.001$) for islets from lean subjects (n = 3), 31.25 ± 2.8 versus 15.3 ± 1.3 ng/ml/10 islets/90 min ($p < 0.001$) at 8.3 mM glucose and 31.2 ± 3.2 versus 21.35 ± 1.9 ng/ml/10 islets/90 min ($p < 0.01$) at 16.7 mM glucose. Finally, in islets issued from lean subjects, pharmacological blockade of nNOS with 10 mM L-NAME stimulated insulin secretion from 15.3 ± 1.3 to 22.4 ± 2.4 ng/ml/10 islets/90 min ($p < 0.01$) at 8.3 mM glucose and from 21.35 ± 1.9 to 27.7 ± 2.8 ng/ml/10 islets/90 min ($p < 0.05$) at 16.7 mM glucose, confirming that nNOS exerts an inhibitory tone on insulin secretion. In contrast, islets from obese subjects were found insensitive to L-NAME, whatever the glucose concentration studied, suggesting a constitutive defect of nNOS.
Conclusion: Islets from obese subjects display molecular and functional abnormalities of nNOS that could be involved in early dysfunctions observed in these islets, as previously observed in an animal model of prediabetic state.

OP 17 Role of mitochondria in muscle insulin action

97

High oxidative capacity protects against lipid-induced insulin resistance
E. Phielix[1], R.C.R. Meex[2], J. Hoeks[1], L. Sparks[1], E. Moonen-Kornips[1], M.K.C. Hesselink[2], P. Schrauwen[1];
[1]Human Biology, [2]Human Movement Sciences, Maastricht University Medical Centre, Netherlands.

Introduction: Fat accumulation in skeletal muscle combined with low mitochondrial oxidative capacity, is associated with muscular insulin resistance. Endurance trained athletes, characterized by high oxidative capacity, have elevated amounts of intramyocellular lipid, yet are highly insulin sensitive. This suggests that a high oxidative capacity may prevent lipid-induced insulin resistance. We examined whether athletes are protected against lipid-induced insulin resistance. In addition, we examined whether ex vivo mitochondrial function deteriorates upon elevation of circulating fatty acids in healthy young men.
Methods: Nine endurance-trained athletes and 10 control subjects with a sedentary lifestyle were included and matched for age (23.4 ± 0.9 and 21.9 ± 0.9 y). Subjects underwent a 6h hyperinsulinemic-euglycemic clamp with simultaneous infusion of a triglyceride emulsion (intralipid) or glycerol. The rate of insulin-stimulated glucose disposal (Rd), oxidative (CHOox) and non-oxidative glucose (NOGD) disposal were computed as the difference between insulin stimulated conditions minus non-insulin stimulated conditions. Muscle biopsies from the m. vastus lateralis were taken before and after the clamp to measure ex vivo mitochondrial function in the addition of several substrate combinations. Mitochondrial function was determined as ADP-stimulated respiration, uncoupled respiration and maximal oxidative capacity, all expressed as pmol/(s*mg)/ mtDNA copy number.
Results: Endurance trained subjects had higher VO2max values compared to control subjects (61.5 ± 1.2 vs 43.0 ± 1.1 ml kg-1 min-1, $p<0.01$). Interestingly, although mitochondrial content was higher in trained subjects, ex vivo mitochondrial function normalized to mtDNA copy number was similar between trained and control subjects. Rd was 63% lower after intralipid compared to glycerol in control subjects (from 35.7 ± 2.7 to 12.0 ± 3.1 μmol kg-1 min-1, $p<0.05$). In contrast, Rd reduced only 29% upon lipid in trained subject (from 45.9 ± 3.6 to 31.6 ± 3.9 μmol kg-1 min-1, $p<0.05$), which was different from untrained subjects ($p<0.05$). The stimulation of CHO-ox by insulin as seen in the glycerol condition was completely blunted after intralipid in both groups. Interestingly, in trained subjects insulin-stimulated NOGD was unaffected upon intralipid, but reduced by 52% in control subjects (from 29.1 ± 2.7 to 14.0 ± 3.4 μmol kg-1 min-1, $p<0.05$). Finally, in both groups respiration values upon intralipid were not different from after glycerol and were unaffected by training status.
Discussion: We show that lipid-induced insulin resistance is blunted in athletes. Interestingly, lipid infusion reduced the insulin-stimulated increase in carbohydrate oxidation rates to a similar extend in trained and untrained subjects, but the non-oxidative glucose disposal was completely unaffected in athletes. These results suggest that a high oxidative capacity prevents lipid-induced reduction of non-oxidative glucose storage and thereby blunts lipid-induced insulin resistance. Higher oxidative capacity in athletes was due to higher mitochondrial density and not intrinsic mitochondrial function, suggesting that the latter may be of less importance in lipid-induced insulin resistance. Finally, mitochondrial function does not deteriorate upon the infusion of lipids.

Adiponectin and AdipoR1 regulate PGC-1alpha and mitochondria by Ca2+ signalling and AMPK/SIRT1 like exercise
T. Yamauchi, M. Iwabu, M. Okada-Iwabu, K. Ueki, T. Kadowaki;
Department of Metabolic Diseases, University of Tokyo, Japan.

Background and aims: Adiponectin is an anti-diabetic adipokine. Its receptors AdipoRs possess a seven-transmembrane topology with the amino terminus located intracellularly, which is opposite to G-protein coupled receptors. Intracellular signal transduction mechanisms of AdipoRs have yet to be well clarified. Insulin resistance has been reported to be associated with impaired skeletal muscle oxidation capacity and mitochondrial dysfunction. However,

the exact cause of mitochondrial dysfunction has yet to be ascertained. We attempted to clarify whether decreased adiponectin/AdipoR1 signalling could be associated with mitochondrial dysfunction, and attempted to elucidate the signalling mechanisms by which adiponectin/AdipoR1 would exert their biological effects.
Materials and methods: We analyzed muscle-specific AdipoR1-knockout mice.
Results: Adiponectin induces extracellular Ca2+ influx via AdipoR1, which was necessary for subsequent activation of Ca2+ /calmodulin-dependent protein kinase kinase β (CaMKKβ) and AMPK/SIRT1, increased expression and decreased acetylation of peroxisome proliferator-activated receptor gamma coactivator-1 alpha (PGC-1α), and increased mitochondria in myocytes. Next we showed that muscle-specific disruption of AdipoR1 resulted in decreased elevation of the intracellular Ca2+ concentration and decreased activation of CaMKK/AMPK/SIRT1 by adiponectin as well as decreased expression and increased acetylation of PGC-1 alpha, decreased mitochondrial content and enzymes such as cytochrome c (CytC), decreased oxidative type I myofibers, decreased oxidative stress-detoxifying enzymes such as catalase and manganese superoxide dismutase (SOD2), and decreased molecules involved in fatty-acid oxidation such as medium-chain acyl-CoA dehydrogenase (MCAD), thereby leading to increased oxidative stress and increased tissue triglyceride content in skeletal muscle. Furthermore, muscle-specific AdipoR1 knockout mice exhibited increased phosphorylation of p70 S6 kinase and JNK and also increased serine phosphorylation of IRS-1 as well as decreased glucose transporter (GLUT)4 expression and decreased Akt activation by insulin, which were associated with decreased rates of glucose disposal (Rd). Importantly, these alterations could result in insulin resistance and decreased exercise endurance. Moreover, AdipoR1 and AdipoR2 double knockout mice as well as obese diabetic db/db mice exhibited almost all the same phenotypes in skeletal muscle observed in muscle-specific AdipoR1 knockout mice. Interestingly, AMPK activator AICAR could only partially rescue the phenotypes of muscle-specific AdipoR1 knockout mice such as insulin resistance and decreased mitochondrial content and function, whereas exercise almost completely rescue their phenotypes.
Conclusion: AdipoR1 appears to 1) regulate mitochondrial function and oxidative stress in muscle as well as insulin sensitivity and exercise endurance, and 2) be required for adiponectin-induced PGC-1α expression and activation via extracellular Ca2+ influx and AMPK/SIRT1, respectively, and subsequent mitochondrial bioenergetics stimulated with adiponectin in muscle cells. Decreased levels of adiponectin/AdipoR1 in obesity may play causal roles in mitochondrial dysfunction and insulin resistance seen in diabetes. Agonism of AdipoR1 as well as strategies to increase AdipoR1 in muscle could be exercise-mimetics.

99

Acute overexpression of PGC-1β in rat skeletal muscle increases mitochondrial substrate oxidation and ameliorates lipid-induced insulin resistance

L.E. Wright[1], A.E. Brandon[1], A.J. Hoy[1], C.J. Lelliott[2], G.J. Cooney[1], N. Turner[1];
[1]Garvan Institute of Medical Research, Darlinghurst, Australia,
[2]AstraZeneca R&D, Mölndal, Sweden.

Background and aims: Lipid accumulation in skeletal muscle is strongly associated with the development of insulin resistance. In particular, reactive lipid species, such as diacylgycerols (DAG), ceramides, and long-chain acyl-CoAs (LCACoA) are thought to antagonize numerous intracellular pathways, which ultimately leads to reductions in insulin sensitivity. Recent data has also implicated oxidative stress as a key determinant in this process. Upregulation of mitochondrial capacity has been suggested as a potential approach to combat lipid overload and insulin resistance in skeletal muscle, however there is relatively little direct data to support this concept. In the current study we aimed to acutely overexpress PGC-1β in hindlimb skeletal muscle from chow and high-fat fed rats, and investigate the effect on mitochondrial function and insulin sensitivity.
Materials and methods: Rats were fed either a low-fat or high-fat diet for 4wk, and *in vivo* electroporation was used to overexpress PGC-1β in the tibialis cranialis and extensor digitorum longus muscles. Downstream effects of PGC-1β on markers of mitochondrial oxidative capacity and muscle lipid levels were characterized, and insulin action was examined *ex vivo* using intact muscle strips and *in vivo* via a hyperinsulinemic-euglycemic clamp.
Results: PGC-1β expression was increased >100% over basal levels. This upregulated the expression of many metabolic proteins, including those involved in mitochondrial function (ETC complexes I and II), lipid metabolism (CD36, CPT-1) and antioxidant defences (SOD-1, SOD-2). Additionally, the activity of oxidative enzymes and substrate oxidation (pyruvate and palmitate) was increased in muscles overexpressing PGC-1β. LCACoA was increased 2.3 fold in control muscles of high-fat fed rats, but remained similar to chow levels in muscles overexpressing PGC-1β ($p<0.05$, n=7). Under hyperinsulinemic-euglycemic clamp conditions, insulin-stimulated glucose uptake was decreased in tibialis cranialis (-20%, $p<0.05$) and extensor digitorum longus (EDL; -28%, $p<0.01$) muscles of high-fat fed rats, and was partially restored towards control levels with PGC-1β overexpression ($p<0.01$). Furthermore in isolated EDL strips, PGC-1β overexpression ameliorated the reduced insulin-stimulated glucose uptake observed with high-fat feeding ($p<0.01$). Finally, in PGC-1β overexpressing muscles we observed a significant decrease in two measures of oxidative stress; lipid peroxidation (-14% in chow fed, -19% in high-fat fed, $p<0.05$) and protein carbonylation (-15% in chow fed $p<0.05$).
Conclusion: These studies demonstrate that physiological overexpression of the transcriptional coactivator PGC-1β in rat skeletal muscle *in vivo* activates a coordinated subset of genes involved in mitochondrial function and substrate oxidation. This prevents diet-induced LCACoA accumulation, ameliorates oxidative damage, and significantly improves insulin action in the skeletal muscle.

Knockdown of hypoxia-inducible factor-1 alpha ameliorates insulin-stimulated glucose uptake in the skeletal muscle cells

H. Sakagami, Y. Makino, K. Mizumoto, T. Isoe, Y. Takeda, J. Watanabe, Y. Fujita, Y. Takiyama, A. Abiko, M. Haneda;
Division of Metabolism and Biosystemic Science, Department of Medicine, Asahikawa Medical College, Asahikawa, Japan.

Background and aim: Impaired insulin sensitivity in peripheral tissues comprises a major cause of hyperglycemia in type 2 diabetes mellitus. Skeletal muscle is the largest organ responsible for insulin-dependent glucose disposal thus plays important part in the regulation of blood glucose homeostasis. Molecular mechanism determining glucose uptake by skeletal muscle in response to insulin, however, remains largely unknown. The hypoxia-inducible factor-1alpha (HIF-1alpha) is a transcription factor operating in the cellular homeostatic regulation under hypoxic conditions. Recent studies have uncovered pleiotropic actions of HIF-1alpha in response to various cellular stimuli including insulin under normoxic condition. Physiological relevance of HIF-1alpha in regulation of insulin action in the target organs, however, has not been well documented. In the present study, we examined the role of HIF-1α in regulation of glucose uptake by the skeletal muscle cells.
Materials and Methods: C2C12 myoblast in which HIF-1alpha is knocked-down (C2C12-deltaHIF) was generated by a stable transfection with HIF-1alpha shRNA expression plasmids. C2C12-deltaHIF myoblasts were differentiated into myotubes then the glucose uptake rate of the cells treated with insulin was determined by monitoring the influx of [^{3}H]-2-deoxy glucose (2-DG).
Results: Upon the treatment with 100nM insulin for 30 minutes, wild type C2C12 myotube increased uptake of 2-DG by 2-fold compared to the basal level. Knockdown of HIF-1alpha in the myotubes (C2C12-deltaHIF) resulted in abrogation of insulin-dependent glucose uptake. Accordingly, in C2C12-deltaHIF myotubes GLUT4 translocation to plasma membrane by treatment with insulin was severely inhibited. The Akt substrate of 160 kDa (AS160), a Rab-GTPase activating protein is known to be responsible for GLUT4 vesicle transport. Immunoprecipitation assays demonstrated insulin-dependent phosphorylation of AS160 in wild type C2C12 myoutubes. Contrary, in C2C12-deltaHIF myotube phosphorylation of AS160 by insulin was significantly reduced. On the other hand, adiponectin, an adipose-derived cytokines, induced GLUT4 translocation and glucose uptake in an additive manner to insulin to demonstrate its insulin-sensitizing action in wild type C2C12 myoutubes. Of interest, both insulin and adiponectin enhanced HIF-1alpha expression in the wild type myotubes. On the other hand, in C2C12-deltaHIF myotubes adiponectin did not demonstrate any additive enhancing effect on glucose uptake by insulin. Finally, we determined glucose uptake by the skeletal muscles of heterozygote of HIF-1alpha gene knock-out mice (HIF-1alpha$^{+/-}$). Extensor digitorum longus (EDL) muscles were isolated from the wild type mice and HIF-1alpha$^{+/-}$ mice to carryout *ex vivo* culture. Insulin stimulated 2-DG uptake was increased up to 3-fold above basal levels in wild type mice. In contrast, HIF-1alpha $^{+/-}$ mice demonstrated significantly reduced uptake of 2-DG either in basal or in insulin-stimulated condition.

Conclusion: HIF-1alpha is a critical determinant for insulin sensitivity and glucose disposal in the skeletal muscle thus as a possible target to alleviate insulin resistance in type 2 diabetes.

Deletion of the Rab-GAP protein TBC1D1 protects from lipid-induced insulin resistance in skeletal muscle

A. Chadt[1], F. Carlotti[2], R.C. Hoeben[2], H.-G. Joost[1], H. Al-Hasani[1];
[1]Pharmacology, German Institute of Human Nutrition, Nuthetal, Germany,
[2]Molecular Cell Biology, Leiden University Medical Center, Netherlands.

Background and aims: The Rab-GTPase-activating (GAP) protein TBC1D1 is highly expressed in skeletal muscle and was recently linked to severe human obesity. We previously described its role as susceptibility gene for high-fat diet-induced obesity and diabetes in mice. TBC1D1-deficient recombinant congenic mice displayed reduced adiposity and a lowered respiratory quotient (RQ), indicating enhanced whole body lipid use. Consequently, intact isolated skeletal muscles from these animals showed increased fatty acid (FA) oxidation with concomitant decrease of insulin-stimulated glucose uptake, indicating that TBC1D1 regulates substrate preference in skeletal muscle. An impaired adaptation of skeletal muscle fuel preference to the availability of glucose and FA as energy substrates has been associated with the development of insulin resistance and diabetes. We therefore sought to investigate the role of TBC1D1 in glucose and lipid metabolism and the mediation of lipid-induced insulin resistance in skeletal muscle.
Materials and methods: C2C12 myotubes were electroporated with siRNA oligonucleotides to achieve *Tbc1d1* knockdown and subsequently exposed to different concentrations (0 - 750 μM) of palmitic acid for 16 h. In addition, intact skeletal muscles (EDL and soleus) from TBC1D1-deficient mice and wildtype controls were isolated and preincubated with increasing concentrations of palmitate. Insulin-stimulated 2-deoxyglucose (DOG) uptake and palmitate oxidation was determined using radioactive tracer techniques. Expression analysis was performed by quantitative real-time PCR and Western Blot.
Results: In cultured C2C12 myotubes, siRNA-mediated knockdown of *Tbc1d1* increased palmitate oxidation by approx. 30%. Likewise, isolated muscles from TBC1D1-deficient mice showed increased palmitate oxidation compared to muscles from wildtype littermates. In both cultured cells and isolated muscles, the enhanced FA combustion was accompanied by increased levels of mRNA for genes involved in lipid metabolism including *Acadl*, *Cd36*, *Ppargc1*, and *Fabp3*. Importantly, additional knockdown of *Cd36* in *Tbc1d1*-depleted C2C12 myotubes completely abrogated the increase in palmitate uptake. Exposure of C2C12 myotubes and isolated skeletal muscles to palmitic acid led to a substantial and dose-dependent reduction in insulin-stimulated AKT phosphorylation, and expression of *Ppargc1* mRNA, respectively. As a result, in the presence of 1 mM palmitate, the insulin-stimulated DOG uptake in isolated skeletal muscles was reduced by >50%. In contrast, depletion of TBC1D1 almost completely prevented the detrimental effect of palmitate on insulin-stimulated AKT phosphorylation, *Ppargc1* expression and insulin-stimulated DOG uptake, and thus restored insulin sensitivity in muscle cells.
Conclusion: Our data demonstrate that TBC1D1 deficiency protects skeletal muscle from lipid-induced insulin resistance, presumably by enhancing FA oxidation. In cultured myotubes, the fatty acid translocase FAT/CD36 is essential for TBC1D1-mediated FA uptake. Furthermore, we show that TBC1D1 exerts control on fuel selection and energy metabolism in skeletal muscle at least in part through the coordinated regulation of gene expression of key enzymes for lipid uptake and oxidation.

Electrical pulse stimulation of human skeletal muscle cells mimics exercise and prevents insulin resistance induced by adipocyte-conditioned medium

S. Lambernd, K. Eckardt, A. Schober, B. Platzbecker, J. Eckel;
Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Skeletal muscle is one of the major insulin sensitive tissues and is responsible for about 80 % of the postprandial insulin-stimulated glucose uptake. Obesity is closely associated with muscle insulin resistance and a major risk factor for the pathogenesis of type II diabetes. Regular physical activity does not only prevent obesity, but also considerably improves insulin sensitivity and skeletal muscle metabolism. Exercise leads to activation of AMPK, enhances insulin signalling and improves glucose uptake. The aim of our project is to establish and characterise an in vitro model of human skeletal muscle contraction to study signalling pathways and mechanisms, which are involved in beneficial effects of muscle activity.
Materials and methods: Differentiated primary human skeletal muscle cells (hSKM cells) were stimulated with a C-pace pulse generator for up to 24 h (1 Hz, 11.5 V, 2 ms pulse duration), and immunofluorescence staining of sacromeric alpha-actinin was used to visualise the cytoskeleton. To induce insulin resistance, hSKM cells were incubated with adipocyte-derived conditioned media (CM) for 8 h. Afterwards, the cells were stimulated with 100 nM insulin for 10 min and lysed. Protein expression and phosphorylation of Akt and AMPK were analysed by SDS-PAGE and western blotting.
Results: After 2-3 h few myotubes started to contract and after 24 h most of the myotubes showed noticable contractile activity. While the protein expression level of sarcomeric alpha-actinin did not change, immunofluorescence staining showed de novo formation of sarcomeres with typical striated pattern. During contraction, AMPK phosphorylation increased over time and was significantly elevated after 8 h of contraction (5fold, n = 6). In addition, electric pulse stimulation of hSKM cells for 24 h led to increased secretion of IL-6 which was 2fold elevated compared to unstimulated controls (114 ± 40 pg/ml to 221 ± 68 pg/ml, n = 6). The incubation of hSKM cells with CM significantly reduced the insulin-stimulated phosphorylation of Akt (Ser473) by 35 % compared to non-treated controls. However, when the cells were pulse-stimulated during the incubation with CM the effect of CM on insulin-stimulated Akt phosphorylation was abrogated.
Conclusion: Our data show that the effects of electric pulse stimulation on hSKM cells were similar to the effect of exercise on skeletal muscle in terms of enhanced AMPK activation and IL-6 secretion. Furthermore, we observed de novo formation of functional active sarcomeric structures. The CM-induced impairment of insulin signalling could be prevented by contractile activity of hSKM cells. This result provides a direct evidence for the beneficial effect of muscle contraction activity in order to improve insulin sensitivity in conditions of insulin resistance. In summary, our model provides a unique tool to investigate mechanisms and underlying signalling pathways which mediate the beneficial effects of muscle contraction, and will help to further clarify the potential of exercise to combat insulin resistance.

OP 18 Diabetic nephropathy - experimental

Effect of CB2 receptor activation in experimental diabetic nephropathy

F. Barutta, R. Gambino, S. Pinach, P. Cavallo Perin, G. Gruden;
Department of Internal Medicine, University of Turin, Italy.

Objective: Diabetic nephropathy (DN) is characterised by increased glomerular permeability to proteins and excessive extracellular matrix accumulation in the mesangium, resulting eventually in glomerulosclerosis and progressive renal impairment. Endogenous cannabinoids (EC), anandamide and 2-arachidonoylglycerol, bind to two endocannabinoid receptors, named CB1 and CB2. We have recently reported that the CB1 receptor is overexpressed by podocytes in experimental diabetes and that CB1 blockade prevents podocyte protein downregulation and reduces albuminuria, indicating a deleterious effect of EC signalling through the CB1 receptor. Coexpression of both the CB1 and the CB2 receptors has been reported in several cell types. In addition, recent studies have shown that activation of the CB2 receptor has protective effects in experimental models of atherosclerosis, liver fibrosis, and cardiac ischemia/reperfusion injury through prevention of inflammatory and profibrotic processes. Therefore, our aim was to study if the CB2 receptor is expressed within the glomeruli and the effect of CB2 activation in experimental diabetic nephropathy.
Methods: Male C57Bl6 mice were made diabetic by intraperitoneal (IP) injection of streptozotocin at a dose of 55 mg/kg in citrate buffer delivered in 5 consecutive days. Control mice were injected with citrate buffer alone. After the onset of diabetes both control (ND n=13) and diabetic mice (DM n=21) were further randomised to receive treatment with either AM1241, a selective CB2-receptor agonist (3 mg/kg IP daily), or vehicle. 14 weeks after the induction of diabetes, mice were individually placed in metabolic cages for urine collections and blood samples taken for blood glucose and glycated haemoglobin measurements. Then, mice were sacrificed, kidneys removed, weighed, and analysed. Urinary albumin excretion was measured by enzyme-linked immunosorbent assay. CB2 receptor protein expression was studied by immunohistochemistry. Nephrin, synaptopodin, zonula occludens-1 (ZO-1) mRNA and protein expression were assessed by immunofluorescence and real-time PCR, respectively. Fibronectin, CTGF, and TGF-β1 mRNA levels were quantitated by real-time PCR on total renal cortex.
Results: The CB2 receptor was expressed within the glomeruli in a predominant podocyte distribution. Diabetes was associated with reduced body weight and elevations in both plasma glucose and glycated haemoglobin levels, but no differences were seen between treated and untreated mice. Albuminuria was significantly ($p<0.001$) increased in the diabetic animals [DM:296.86 (252.8-356.2) μg/18hrs, geometric mean (25^{th}-75^{th} percentile)] as compared to the controls [ND:78.87 (73.8-86.6)] and ameliorated by treatment with AM1241 [ND+AM1241:67.75 (59.9-77.3); DM+AM1241:183.59 (144.8-243.5); $p<0.01$ DM vs DM+AM1241]. In the diabetic mice the increase in albuminuria was paralleled a significant three-fold reduction in both nephrin and ZO-1 protein expression and this effect was completely prevented in mice treated with AM1241. Similarly, diabetes-induced downregulation of both nephrin and ZO-1 mRNA levels was abolished by AM1241. By contrast in diabetic mice AM1241 administration did not affect fibronectin, TGF-β1, and CTGF overexpression.
Conclusion: These findings demonstrate that the CB2 receptor is expressed within the glomeruli and that CB2 activation ameliorates the diabetic proteinuria, possibly via prevention of podocyte slit diaphragm protein loss.

Poly(ADP-ribose) polymerase-1 (PARP-1) gene deficiency alleviates diabetic kidney disease

H. Shevalye, Y. Maksimchyk, P. Watcho, I.G. Obrosova;
Mechanisms of Diabetes Complications, Pennington Biomedical Research Center, Baton Rouge, USA.

Background and aims: Evidence for the important role of poly(ADP-ribose)polymerase-1 (PARP-1) in chronic diabetic complications is emerging. Several structurally unrelated PARP-1 inhibitors have been reported to prevent or alleviate diabetic nephropathy. This study evaluated further the role for PARP-1 in diabetic kidney disease using the PARP-1-deficient mouse.
Materials and methods: PARP-1-/- and the wild-type (129S1/SvImJ) mice were made diabetic with streptozotocin, 40 mg $kg^{-1}d^{-1}$, i.p., for, at least, 7 consecutive days, and were maintained for 12 weeks. PARP-1 and poly(ADP-ribosyl)ated protein levels were evaluated by Western blot analyses, and urinary albumin excretion and renal cortex nitrotyrosine and transforming growth factor-β_1 (TGF-β_1) concentrations by ELISA. Glomerular collagen deposition and mesangial expansion (PAS-positive staining) were evaluated by histochemistry, followed by quantitation with the Threshold Colour plug-in of ImageJ 1.43q and ImageJ 1.43q programs, respectively. Podocyte nuclei were detected with an anti-WT1 antibody, by immunohistochemistry. Podocyte numbers were counted per glomerular section, and 20-25 glomeruli were examined for each animal.
Results: Final blood glucose concentrations were ~3.7-fold higher in both diabetic groups than in controls. PARP-1 and poly(ADP-ribosyl)ated protein levels in the renal cortex were similar in non-diabetic and diabetic wild-type mice (100% and 107%) whereas all knockouts were PARP-1-negative. Poly(ADP-ribosyl)ated proteins, however, have been identified in all groups, and their levels were increased by 18% and 14% in diabetic wild-type and diabetic PARP-1-/- mice, compared with the corresponding controls. Diabetes was associated with ~21-fold and ~13-fold increases in albuminuria in wild-type and PARP-1-/- mice, respectively. PARP-1 gene deficiency prevented diabetes-induced kidney hypertrophy and alleviated mesangial expansion and collagen deposition. Renal podocyte loss, and nitrotyrosine and transforming growth factor-β_1 accumulations were slightly lower in diabetic PARP-1-/- mice, but the differences with the diabetic wild-type group did not achieve statistical significance.
Conclusion: PARP-/- gene deficiency alleviates although does not completely prevent diabetic kidney disease. The lack of a complete prevention could be related to the presence of other PARPs responsible for poly(ADP-ribosyl)ation in the renal cortex in PARP-1-deficient mouse and its increase in diabetes, and/or streptozotocin nephrotoxicity in mice.

TIMP3 deficiency accelerates diabetic nephropathy

M. Cavalera[1], L. Fiorentino[1], M. Fabrizi[1], M. Mavilio[1], S. Menini[2], G. Pugliese[2], D. Lauro[1], A. Urbani[1], R. Lauro[1], M. Federici[1];
[1]Dept. of Internal Medicine, University of Tor Vergata, [2]Dept. of Clinical Sciences, University La Sapienza, Rome, Italy.

Background and aims: Some experimental models of nephropathy have recently shown that activation of TACE/ADAM17 is a key step in the progression of glomerulopathy, even though the exact role of ADAM17 and its inhibitor TIMP3in a hyperglycemic environment is still unclear.
Materials and methods: To test this hypothesis we treated WT mice with streptozocin to induce hyperglycemia, and then measured TACE activity in kidney; we found a significant activation of the enzyme in hyperglycemic (STZ, streptozocin-treated) mice compared to untreated controls ($p<0.001$). Next, we analyzed STZ-WT and STZ-*Timp-3*$^{-/-}$ kidneys by IHC, real time PCR and WB.
Results: STZ-*Timp-3*$^{-/-}$ mice showed significantly increased mean glomerular area and fractional mesangial area ($p<0.05$ and $p<0.001$, respectively). STZ-*Timp-3*$^{-/-}$ mice showed also a thicker glomerular basement membrane, due to an increased amount of type IV collagen deposition ($p<0.01$), that is one of the early feature of diabetic nephropathy. Moreover, they also showed increased macrophage infiltration, measured by F4/80 staining ($p<0.01$), resulting in inflammation. Oxidative stress markers staining revealed that STZ-*Timp-3*$^{-/-}$ mice are characterized by an increased expression of NOX4, RAGE and N-Carboxymethyl-lysine, a major product of oxidative modification of glycated proteins ($p<0.01$ for all). To further analyze the role of TIMP3 in diabetic nephropathy at a molecular level we performed real time PCR on RNA samples derived from kidneys of STZ-*Timp-3*$^{-/-}$ and WT mice. We found that the expression of MCP-1, a marker of inflammation, was significantly increased in STZ-*Timp-3*$^{-/-}$ mice, while the expression of nephrin and WT1, two markers of podocyte functions, is reduced in STZ-*Timp-3*$^{-/-}$ mice compared to the WT littermates ($p<0.01$ for all). We also performed gene profiling experiments on kidneys of the same animals, and we could observe up-regulation of different classes of genes involved in inflammation (*Cxcl9*, *Ccr5*, *Mcp-1*, *Mcp-5*, *Aif-1, Cd36, Mgl-1, Mgl-2*), renal cells proliferation and fibrosis (*Pdgf-d*, *Tgfβ3*, *Fgf, Ghr*), lipid metabolism (*Fabp5, Fasn, Ldlr, Acaca, Acms3*) and transport (*Slc13a1, Slc7a13, Slc7a6, Slco4c1, Slc12a3, Glut8*) in STZ-*Timp-3*$^{-/-}$ mice compared to WT ones. We also found a significant reduction in the expression of genes connected to control of oxidative stress such

as *Foxo1 and Foxo3a* in the kidney of STZ-*Timp-3*$^{-/-}$ mice. Finally, we used a proteomic approach to identify proteins differentially expressed in kidneys of STZ- *Timp-3*$^{-/-}$ and WT mice. Proteomic analysis of total homogenates revealed the presence of the 78 kDa glucose-regulated protein (GRP78) and protein disulfide-isomerase A3 only in kidneys from STZ-treated Timp-3$^{-/-}$ mice, indicating an increased levels of endoplasmic reticulum stress in these mice compared to WT ones.
Conclusion: In conclusion, our preliminary results show that Timp3 plays a protective role in preventing inflammation and oxidative stress accumulation in kidney and, doing so, it can interfere with the development and progression of diabetic renal nephropathy.

D-carnosine prevents diabetic nephropathy in db/db mice
C. Iacobini[1], S. Menini[1], C. Ricci[1], A. Scipioni[1], C. Blasetti-Fantauzzi[1], A. Giaccari[2], E. Salomone[2], A. Lapolla[3], M. Orioli[4], G. Aldini[4], F. Pugliese[1], G. Pugliese[1];
[1]Department of Clinical Sciences, La Sapienza University, Rome, [2]Department of Endocrinology, Catholic University, Rome, [3]Department of Medical and Surgical Sciences, University of Padua, Padua, [4]Institute of Pharmaceutical and Toxicological Chemistry, University of Milan, Italy.

Background and aims: The advanced glycation end products (AGEs) are believed to participate in the pathogenesis of diabetic nephropathy by causing both direct modification of enzymatic activity, ligand binding, half-life and immunogenicity of proteins and receptor-mediated pro-inflammatory and pro-fibrotic effects. The endogenous dipeptide L-carnosine was shown to act as a quencher of reactive carbonyl AGE precursors. However, in humans, it is rapidly inactivated by carnosinase. The carnosinase-resistant compound D-carnosine (DC) have shown high activity, selectivity and plasma stability. Preliminary studies from our group have demonstrated that DC is effective in attenuating high fat diet-induced atherosclerosis in ApoE null mice. This study was aimed at evaluating the efficacy of DC in preventing diabetic nephropathy in *db/db* mice.
Materials and methods: Adults (aged 6 weeks) male *db/db* mice and the corresponding *db/m* controls were treated with a DC derivative (60 mg/kg body weight in the drinking water; Flamma S.p.A.) or vehicle for 14 weeks. At the end of this period, urines were collected for assessment of proteinuria, then mice were killed and both kidneys were sampled. Glomerular sclerosis index (GSI) was assessed semiquantitatively, then mean glomerular area (mGA) and fractional mesangial area (fMA) were measured by computer-assisted morphometry, with estimation of mean glomerular volume (mGV) from mGA and calculation of mean mesangial area (mMA) by the formula: (fMA x mGA)/100. Renal expression of inflammatory and disease progression markers as well as kidney content of HNE adducts and AGE receptors were assessed by immunohistochemistry and/or RT-PCR. Serum AGEs and isoprostane-8-epi-$PGF_{2\alpha}$ were measured by ELISA, pentosidine by HPLC and total carbonylated proteins (PCOs) by slot blot immunoassay.
Results: DC treatment induced a significant attenuation of renal disease in *db/db* mice, whereas it did not influence renal structure in *db/m* control mice. Proteinuria (-35%), GSI (-31%), mGA (3.22 ± 0.27 vs. 3.52 ± 0.21 $\mu m^2 x10^3$), mGV (137.5 ± 10.1 vs. 157.2 ± 13.7 $\mu m^3 x10^3$), mMA (428.0 ± 82.5 vs. 588.5 ± 48.7 μm^2) and fMA (13.2 ± 1.8 vs. 16.8 ± 1.7%) decreased significantly ($P<0.001$) in DC-treated *db/db* mice, as compared with untreated animals. Glomerular staining for HNE adducts (5.6 ± 2.7 vs. 13.5 ± 2.8 % of glomerular area) as well as for the extracellular matrix proteins fibronectin (11.7 ± 2.6 vs. 19.7 ± 1.8 % of glomerular area) and collagen IV (13.2 ± 3.4 vs. 24.6 ± 3.1 % of glomerular area) were also significantly reduced ($P<0.001$) in DC-treated vs. untreated *db/db* mice. The mRNA expression levels of F4/80, CXCR3, MCP-1, TNF-α, CHOP, and the AGE receptors RAGE, galectin-3 and CD36 were also significantly lower in *db/db* mice treated with DC. Finally, serum AGE, pentosidine, PCOs, and isoprostane-8-epi-$PGF_{2\alpha}$ levels were lower in DC-treated vs. untreated *db/db* mice.
Conclusion: These data show that DC is effective in reducing carbonyl reactive species and preventing renal injury in *db/db* mice, thus suggesting that carbonyl stress plays a major role in diabetic nephropathy and that DC derivatives might be useful for treatment of this complication.

107

Glucagon like peptide-1 agonist, exendin-4, exerts anti-inflammatory effect on macrophage and glomerular endothelial cell through inhibition of NF-κB
R. Kodera, K. Shikata, K. Hitomi, T. Takatsuka, S. Miyamoto, M. Sasaki, N. Kajitani, S. Nishishita, K. Sarai, D. Hirota, C. Sato, D. Ogawa, H. Makino;
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Japan.

Background and aims: Glucagon like peptide-1 (GLP-1) is known to have various extrapancreatic effects in addition to enhancement of insulin secretion. We have recently shown the renoprotective effects of exendin-4 through anti-inflammatory effects.Exendin-4 suppressed macrophage infiltration, expression of ICAM-1 and type IV collagen and oxidative stress independent of blood glucose lowering actions in diabetic rats. In addition, we have demonstrated that GLP-1 receptor is expressed on glomerular endothelial cells and monocytes/macrophages. The aim of this study is to clarify the mechanism for the protective effects of exendin-4 against diabetic nephropathy.
Materials and methods: Five-week old male Sprague-Dawley rats were divided into four groups: non-diabetic: ND, non-diabetic rats treated with exendin-4: ND+EX, diabetic rats without treatment: DM, diabetic rats treated with exendin-4: DM+EX. Rats were administered intraperitoneally with exendin-4 (10μg/kg/day, ND+EX and DM+EX) or vehicle (ND and DM) every day for 8 weeks. To investigate the mechanisms of anti-inflammatory effects of exendin-4, we evaluated the nuclear factor-κB, p65DNA binding activity in the kidney, which is one of the most important transcription factors regulating both inflammation and oxidative stress. In addition to direct effects of exendin-4 on macrophages and endothelial cells, we examined pro-inflammatory cytokine expressions (TNF-α and IL-1β mRNA) in THP-1 cells by 15mM high glucose for 72 hours and ICAM-1 mRNA expression in human glomerular endothelial cells by 100pg/ml TNF-α for six hours. Furthermore, to confirm whether the effects of GLP-1 directly acted on GLP-1 receptor, we used the GLP-1 receptor antagonist.
Results: The activation of NF-κB p65DNA binding activity in the renal cortex was significantly enhanced in DM group compared with non-diabetic groups. Exendin-4 treatment significantly inhibited the NF-κB p65 DNA binding activity. Stimulation with high glucose enhanced gene expression of TNF-α and IL-1β inTHP-1 cells. Exendin-4 significantly attenuated TNF-α and IL-1β gene expression with dose-dependent manner. The effects of exendin-4 on TNF-α and IL-1β were blocked by GLP-1R antagonist. TNF-α enhanced ICAM-1 gene expression on human glomerular endothelial cells. Exendin-4 dose-dependently attenuated ICAM-1 gene expression. The effect of exendin-4 was blocked by GLP-1R antagonist.
Conclusion: The current results indicate that exendin-4 suppresses the activation of NF-κB in diabetic kidney. Exendin-4 directly acts on GLP-1 receptors and down-regulates the expression of cytokines and ICAM-1 on macrophage and glomerular endothelial cell. Exendin-4 may exert protective effects against diabetic nephropathy by inhibition of the interaction between macrophages and glomerular endothelial cells which promotes inflammatory process.

Altered expression profiles of microRNA in the glomeruli of diabetic mice
T. Takatsuka, K. Shikata, R. Kodera, H. Kataoka, S. Miyamoto, D. Hirota, N. Kajitani, C. Sato, H. Makino;
Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Japan.

Background and aims: The postulated mechanism in the development of diabetic nephropathy involves several factors including protein kinase C activation, TGF-β, AGE, oxidative stress and microinflammation which were induced by long-term exposure to high glucose. However, the therapeutic strategy for diabetic nephropathy has not fully developed, thus, more detail molecular mechanism in the pathogenesis of diabetic nephropathy and new treatment are still desired. The microRNAs, short non-coding RNAs of 21 to 23 nucleotides, have recently been shown to play an important role on biological process, including development, differentiation and proliferation, in various types of cells. We examined microRNA expression profile in renal glomeruli of diabetic mice to clarify the pathogenesis and find a novel therapeutic target of diabetic nephropathy.

Materials and methods: Eight-week-old male C57BL/6J mice were used. Diabetes were induced by intraperitoneal injection with streptozotocin at 200 mg/kg in citrate buffer (DM, n=6). Non-diabetic control mice were injected with citrate buffer (ND, n=5). Blood pressure, blood glucose, HbA1c and urinary excretion of albumin were measured every month. Kidneys were harvested at 6 months after induction of diabetes. Renal glomeruli were isolated magnetically after intra-arterial injection of iron oxide. MicroRNAs were extracted by miRNeasy Mini Kit. Agilent microRNA array (567 mouse microRNAs) was used to analyze the microRNA expression profile.
Results: We identified the total 21 microRNAs that showed a specific expression pattern in DM mice compared with ND mice. Up-regulated microRNAs (1.5 > DM/ND) in DM renal glomeruli were 8 genes (mmu-miR-705, mmu-miR-714, mmu-miR-34a, mmu-miR-21, mmu-miR-221, mmu-miR-141, mmu-miR-689, mmu-miR-671-5p). Down-regulated microRNAs (0.75 < DM/ND) in DM renal glomeruli were 13 genes (mmu-miR-1, mmu-miR-219b-5p, mmu-miR-503, mmu-miR-574-5p, mmu-miR-133b, mmu-miR-197, mmu-miR-466i, mmu-miR-467d, mmu-miR-466f-3p, mmu-miR-574-3p, mmu-miR-335-5p, mmu-miR-322*, mmu-miR-1187).
Conclusion: We identified the microRNAs which showed a specific expression pattern in renal glomeruli of diabetic mice compared with non-diabetic mice. Some of these microRNAs are known to be related to inflammatory process and cell proliferation. Altered expression of these microRNAs may be associated with pathogenesis of diabetic nephropathy.

Estimating the quality of life impact of diabetes related complications: new results from the UKPDS
M.L. Alva[1], A. Gray[1], B. Mihaylova[1], P. Clarke[2];
[1]Department of Public Health, Health Economic Research Centre, Oxford, United Kingdom, [2]Department of Public Heath, University of Sydney, Australia.

Background and aims: Reliable estimates of the quality of life impact of diabetes related complications are important for researchers conducting trial-based and model-based evaluations of the cost-effectiveness of interventions. Previous estimates based on a cross-sectional study of patients enrolled in the UKPDS have been widely used. Here we report updated results drawing on the UKPDS Post Trial Monitoring Study, which allows us to greatly extend follow-up, examine a larger number and wider range of complications, and compare cross-sectional results with those from repeated measures of quality of life over time.
Materials and methods: Quality of life was measured using the EuroQol EQ-5D instrument, which was administered in 1996/7 and again annually over the period 2002-8 to all remaining participants in the study. We estimated the immediate and long term impact on quality of life of myocardial infarction, ischaemic heart disease, stroke, heart failure, amputation, renal failure, blindness in one eye, retinal photocoagulation, cataract extraction and vitreous haemorrhage, controlling for age, sex and diabetes duration. We also compared different methods of estimating these effects.
Results: A total of 4267 UKPDS patients were administered one or more EQ-5D questionnaires. The average number of questionnaires completed was 3.4 and the maximum was 7. Approximately 49% of respondents only answered the questionnaire once. 1425 patients died between 1997 and 2008. The response rate of fully completed questionnaires varied from 68% to 74%. Compared with our original study, many more complications were available for analysis: for example, in our data set the total number of myocardial infarctions increased from 203 in the first questionnaire to 371 across all rounds, the number of amputations from 21 to 89, blindness to one eye from 93 to 197 and stroke from 60 to 171. Mean quality of life was seen to decline from 0.77 at the first questionnaire in 1996/7 to 0.64 in the last questionnaire in 2007/8. This was related to the increasing age of patients over time (62 at first quality of life questionnaire compared with 72 at final questionnaire), and an increasing proportion of patients with a history of complications (27% at first questionnaire compared with 55% at last questionnaire). For those without complications of any sort the average utility across questionnaires was 0.74, compared with 0.66 for those with a history of myocardial infarction, 0.46 with amputation, 0.60 with blindness to 1 eye and 0.53 with stroke.
Conclusion: This paper reports new results from the UKPDS on the quality of life impact of a range of diabetes related complications. These suggest that complications have substantial and long-lasting effects on patient quality of life. The results are based on well-validated patient history and adjudicated complications data from a landmark diabetes study, and should be useful in estimating more accurately the outcome of interventions that reduce these complications.

The majority of type 2 diabetic patients with renal impairment have non-albuminuric renal disease - the Swedish National Diabetes register (NDR)
H. Afghahi[1], H. Hadimeri[1], J. Cederholm[2], B. Eliasson[3], B. Zethelius[4], S. Gudbjörnsdottir[3], M.K. Svensson[3];
[1]Department of Nephrology, Kärnsjukhuset, Skövde, [2]Department of Public Health and Caring Sciences, Family Medicine and Clinical Epidemiology, Uppsala University, [3]Department of Medicine, Sahlgrenska Academy at the University of Gothenburg, [4]Department of Public Health and Caring Sciences/Geriatrics, University of Uppsala, Sweden.

Background and aims: Albuminuria and renal impairment are two main manifestations of renal disease which are not entirely linked in patients with type 2 diabetes (T2D). The aim of this cross-sectional study was to identify the prevalence of non-albuminuric renal impairment in type 2 diabetic patients and to examine the clinical characteristics associated with non-albu-

minuric renal impairment in a large nation-wide population-based diabetes register.

Materials and methods: 62 661 patients with T2D aged 30-80 years with complete datasets on albumin excretion, renal function (serum creatinine) and clinical characteristics reported to the Swedish National Diabetes Register in 2008 were included. Albuminuria was defined as urinary albumin excretion rate > 20 μg/min and renal impairment as estimated glomerular filtration rate; eGFR< 60 ml/min/1.73 m^2 according to MDRD. Logistic regression analyses for clinical and biochemical variables with renal impairment with or without albuminuria as dependent variable were performed. Adjusted odds ratios were calculated and continuous variables were increased per one standard deviation. 95% confidence intervals are given.

Results: 15% of all patients had renal impairment (n=9 308). Among patients with renal impairment 56% were non-albuminuric and 42% were albuminuric. In a multivariate analyses patients with non-albuminuric renal impairment had significantly and independently shorter diabetes duration (adj OR 0.73; 95% CI 0.70-0.76), higher total cholesterol (1.05; 1.01-1.10), lower levels of triglycerides (0.83; 0.80-0.87), lower systolic blood pressure (0.81; 0.78-0.84), better glycemic control (HbA1c%) (0.86; 0.82-0.91), lower BMI (0.88; 0.84-0.93) and were more often female and non-smoking as compared with patients with albuminuric renal impairment.

Conclusion: The majority of patients with type 2 diabetes and renal impairment have non-albuminuric renal disease. Distinct sets of risk factors were associated with the presence or absence of albuminuria, patients with non-albuminuric renal impairment exhibiting less features of the "metabolic syndrome". Non-albuminuric renal impairment could partly be explained by the use of renin angiotensin system inhibitors but our results also support the concept of different underlying pathophysiology mechanisms. Development of markers and methods for a more accurate estimation of renal function in T2D patients without albuminuria is important for screening, follow-up and treatment of these patients.

Risk of progression of nephropathy in a population-based sample with type 2 diabetes

S. Vupputuri[1], G.A. Nichols[2], H. Lau[3], P. Joski[1], M.L. Thorp[2];
[1]The Center for Health Research, Kaiser Permanente Georgia, Atlanta,
[2]The Center for Health Research, Kaiser Permanente Northwest, Portland,
[3]Evidence Based Medicine, Novartis Pharmaceuticals Inc., East Hanover, USA.

Background and aims: Progression through stages of nephropathy has not been well described in a large, well-characterized, population-based study. Estimates of the public health burden of nephropathy may be different in such a population. Our aims were to describe the progression of nephropathy and identify demographic and clinical characteristics associated with progression in a U.S. population-based sample.

Materials and methods: We identified 11,562 members of a managed care organization who had hypertension and type 2 diabetes, a urine albumin-to-creatinine ratio (UACR) measurement in 2001-2003, and at least 1 follow-up UACR. Baseline nephropathy stage was defined as normal albumin (UACR<3.4 mg/mmol), microalbuminuria (3.4-33.9 mg/mmol), and macroalbuminuria (≥33.9 mg/mmol). We searched records through 2008 for progression from baseline to a higher stage of nephropathy including ESRD.

Results: Mean age was 59.4±11.3 years; 49.8% were male, 17.5% African-American, and mean A1C was 8.1%. At baseline, 59% had normal albumin, 30% had microalbuminuria, and 11% had macroalbuminuria. The incidence of nephropathy progression (per 1000 person-yrs) was 94.6, 44.1, and 6.7 for normal albumin, micro-, and macro- albuminuria, respectively. The high rates of progression of nephropathy among those with normal albumin demonstrate that 68% of all patients had developed micro- or macro- albuminuria by the end of follow-up. Most patients received antihypertensive therapy; ACEi/ARB use ranged from 61-67%, except among patients with macroalbuminuria at follow-up. Age, diabetes duration, and A1C were significant predictors of progression.

Conclusion: Our study, one of the first to examine the progression of nephropathy in a U.S population-based sample, showed that among adults with diabetes and hypertension, the lifetime risk of nephropathy and it's progression may be greater than previously reported. Further, the use of ACEi/ARBs to slow and/or prevent the progression of nephropathy may be underutilized.

Prospective association of B-type natriuretic peptide with left ventricular systolic and diastolic function in individuals with and without type 2 diabetes - the Hoorn Study

M.H. Kroon[1], K. van den Hurk[1], M. Alssema[1], O. Kamp[2], C.D.A. Stehouwer[3], R.M.A. Henry[3], M. Diamant[4], F. Boomsma[5], G. Nijpels[1], W.J. Paulus[6], J.M. Dekker[1];
[1]EMGO Institute for Health and Care research, VU Medical Center, Amsterdam, [2]Department of Cardiology, VU Medical Center, Amsterdam, [3]Department of Internal Medicine, AZM, Maastricht, [4]Department of Endocrinology, Diabetes Center, VU Medical Center, Amsterdam, [5]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, [6]Department of Physiology, VU Medical Center, Amsterdam, Netherlands.

Background and aims: Individuals with type 2 diabetes mellitus (T2DM) have an increased risk of developing heart failure (HF). Higher plasma B-type natriuretic peptide (BNP) in a non-heart failure range predicts HF and CVD mortality and is associated with T2DM. We aimed to investigate prospectively in a population based cohort the association of BNP levels in a non heart failure range with left ventricular (LV) mass, LV systolic function, and LV diastolic function in individuals with and without T2DM.

Materials and methods: In the Hoorn Study, a population-based prospective cohort study, plasma BNP (pmol/l) was determined at baseline. A 2D echocardiogram was made at baseline and after 8 years of follow-up to measure LV mass index (LVMI, g/m^2), ejection fraction (EF, %, systolic function) and left atrial volume index (LAVI, ml/m^2, diastolic function). Participants with atrial fibrillation, wall movement abnormalities and moderate or severe aortic or mitral valve disease were excluded. Linear regression analyses, adjusted for gender, age, baseline heart function, use of antihypertensive medication, BMI and heart rate were performed to investigate the association of BNP with LVMI, and LV systolic and diastolic function. In case of significant effect modification ($p<0.10$), we reported the regression coefficients for individuals with and without T2DM separately.

Results: Of the 796 individuals of whom echocardiograms at baseline were present, 441 (55%) attended the follow-up examination (baseline age 66 years, 34% T2DM). Increase in LVMI was greater in those with higher baseline BNP (Table 1). The association was stronger in patients with T2DM, and in non-T2DM the association was explained by baseline LVMI, BMI and use of antihypertensives, in T2DM the association was independent. Regardless of T2DM, a 10 pmol/l higher baseline BNP was associated with a 2.7% lower EF and a 5.0 ml/m^2 higher LAVI at follow-up.

Conclusion: This study shows that BNP levels are prospectively associated with LV diastolic and systolic function and that there is a strong association between BNP levels in a non-heart failure range and LVMI for individuals with T2DM and not for those without.

Table 1: Coefficients (95% CI) per 10 pmol increase of baseline BNP for LVMI, EF and LAVI (follow-up)

LVMI (g/m2)	**non-T2DM** n = 161	**T2DM** n = 86
Crude model	5.7 (-0.03 - 11.5)	25.1 (11.0 - 39.3)*
adjusted for gender and age	6.5 (1.0 - 11.9)*	26.3 (11.4 - 41.2)*
+ adjusted for baseline LVMI, antihypertensives, BMI and heart rate	1.1 (-4.6 - 6.8)	29.1 (13.6 - 44.6)*
EF (%, LV systolic function)	Total population n = 235	
Crude model	-2.3 (-4.4 - - 0.1)*	
adjusted for gender and age	-2.3 (-4.5 - - 0.1)*	
+ adjusted for baseline EF, antihypertensives, BMI and heart rate	**-2.7** (-4.9 - - 0.4)*	
LAVI (ml/m2, LV diastolic function)	n = 268	
Crude model	7.3 (5.3 - 9.2)*	
adjusted for gender and age	7.0 (5.1 - 9.0)*	
+ adjusted for baseline LAVI, antihypertensives, BMI and heart rate	5.0 (2.9 - 7.1)*

Arterial stiffness is prospectively associated with left ventricular diastolic function in individuals with and without type 2 diabetes - The Hoorn Study

K. van den Hurk[1], M. Alssema[1], O. Kamp[2], R.M.A. Henry[3], C.D.A. Stehouwer[3], Y.M. Smulders[4], G. Nijpels[5], W.J. Paulus[6], J.M. Dekker[1];
[1]Department of Epidemiology and Biostatistics, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [2]Department of Cardiology, VU University Medical Center, Amsterdam, [3]Department of Internal Medicine, Maastricht University Medical Centre, Maastricht, [4]Department of Internal Medicine, VU University Medical Center, Amsterdam, [5]Department of General Practice, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [6]Department of Physiology, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: Left-sided heart failure (HF), especially with a normal ejection fraction, is common with type 2 diabetes (T2DM), but the underlying mechanisms remain controversial. Arterial stiffness is suggested as a potential cause of HF. We investigated whether arterial stiffness was prospectively associated with a higher left ventricular (LV) mass and worse LV diastolic function and whether this differed in individuals with or without T2DM.
Materials and methods: In the Hoorn Study, a population-based cohort study of diabetes, echocardiography and arterial ultrasonography was performed in 2000 and 2008. Linear regression analyses were performed to investigate associations of carotid, brachial and femoral artery distensibility coefficients (DC, arterial stiffness) with LV mass index (LVMI, g/m^2) and left atrial volume index (LAVI, ml/m^2, LV diastolic function). Individuals with moderate or severe mitral or aortic valve disease, or tachycardia (heart rate>90bpm) were excluded. Analyses were adjusted for age, sex, BMI, and baseline value of the outcome. Influence of T2DM or medication use was investigated by stratified analyses.
Results: Of the 796 individuals of whom echocardiograms at baseline were present, 441 (baseline age 66 years, 34% T2DM of whom 80% were newly diagnosed) attended the follow-up. Non-attendees were older, had lower DCs and higher LVMI and LAVI as compared to attendees. In crude analyses, femoral and carotid DC were significantly associated with LVMI, however this was explained by age and sex differences. Associations between DCs and LAVI were not different for individuals with or without T2DM (p for interaction >0.10). Individuals with T2DM had at baseline already lower DCs and higher LAVI compared to those without T2DM. In individuals who did not use lipid or glucose lowering medication, every 10^{-3} kPa^{-1} lower baseline brachial and femoral DC was independently associated with a 0.41 (95% CI: 0.14-0.67) or 0.68 (0.12-1.23) ml/m^2 higher LAVI, respectively. Associations adjusted for mean arterial pressure were 0.36 (0.09-0.63) and 0.57 (-0.01-1.14, NS) ml/m^2 higher LAVI per 10^{-3} kPa^{-1} lower DCs. The associations were absent in those who used glucose and/or lipid lowering medication. Further adjustments for HbA_{1c}, heart rate, LVMI, systolic BP or use of antihypertensive medication did not change our results.
Conclusion: Arterial stiffness was prospectively associated with a worse LV diastolic function, regardless of T2DM. These associations were only partly explained by mean arterial pressure. Because individuals with T2DM commonly have stiffer arteries than those without T2DM, our finding indicates that arterial stiffening might be one of the causes of a worse LV diastolic function in individuals with T2DM.

Natural course of glucose effectiveness in nondiabetic and diabetic individuals: the Insulin Resistance Atherosclerosis Study

C. Lorenzo[1], L.E. Wagenknecht[2], A.J. Karter[3], A.J.G. Hanley[4], J.M. Norris[5], S.M. Haffner[6];
[1]Medicine, University of Texas Health Science Center, San Antonio, [2]Wake Forest University School of Medicine, Winston-Salem, [3]Kaiser Permanente, Northern California Region, Oakland, USA, [4]Nutritional Sciences and Medicine and Leadership Sinai Centre for Diabetes, Mt. Sinai Hospital and University of Toronto, Canada, [5]Department of Epidemiology, Colorado School of Public Health. University of Colorado Denver, Aurora, [6]Medicine, Baylor College of Medicine, Houston, USA.

Background and aims: Disposition index (DI), the product of insulin sensitivity and secretion, decreases as glucose tolerance status deteriorates. Glucose effectiveness (S_G), the ability of glucose to enhance its own cellular uptake and to suppress endogenous glucose production, is also a risk factor for type 2 diabetes, but the natural course of S_G is not well characterized. Thus, we examined the natural course of S_G relative to that of DI in participants in the Insulin Resistance Atherosclerosis Study (IRAS).
Materials and methods: DI and S_G were measured in 923 IRAS participants aged 40 - 69 years (Hispanics, non-Hispanic whites, and African Americans) by the frequently sampled intravenous glucose tolerance test. DI and S_G were also measured using the same protocol at the 5-year follow-up examination. DI was expressed as the product of insulin sensitivity index and acute insulin response. Normal glucose tolerance (NGT), impaired glucose tolerance (IGT), and diabetes were defined by the 1999 World Health Organization criteria. Individuals treated with glucose-lowering medications were excluded.
Results: At baseline, S_G was 1.97 ± 0.03 in individuals with NGT, 1.53 ± 0.05 in those with IGT, and 1.48 ± 0.03 x 10^{-2} min^{-1} in diabetic participants (p_{trend} <0.001). Corresponding values of DI were 103.6 ± 5.4, 27.8 ± 2.4, and 5.2 ± 0.6 x 10^{-4} min^{-1}. μU^{-1}. ml^{-1} per μU/ml (p_{trend} <0.001). S_G was directly related to DI (r = 0.40, p <0.001) by the Spearman's rank test after controlling for age, sex, race/ethnicity, and center. During the follow-up period, DI decreased in all glucose tolerance categories except in individuals who had IGT at baseline and NGT at follow-up (Figure). In individuals with NGT at baseline, the decrease in DI (adjusted for baseline DI) was directly related to worsening of glucose tolerance status during the follow-up period (p_{trend} <0.001). Similar results were observed in individuals with IGT at baseline (p_{trend} <0.001). S_G also decreased with time in all categories but in participants with NGT who had no change of status and in those with IGT whose status improved. In individuals with NGT at baseline, the decrease of S_G (adjusted for baseline S_G) was directly related to worsening of glucose tolerance status during the follow-up period (p_{trend} <0.001); however, results were not statistically significant in those with IGT at baseline (p_{trend} = 0.075).
Conclusion: Failure to maintain DI and S_G results in worsening of glucose tolerance status.

OP 20 Diabetic foot - mechanisms and treatment

115

RANKL/OPG signalling pathway mediates medial arterial calcification in diabetic Charcot neuroarthropathy

A. Ndip[1,2], Y.M. Alexander[2], A. Williams[2], E.B. Jude[3,2], A.J.M. Boulton[1,2];
[1]Department of Medicine and Diabetes, Manchester Diabetes Centre, [2]Cardiovascular Research Group, The University of Manchester, [3]Diabetes Centre, Tameside General Hospital, Ashton-Under-Lyne, United Kingdom.

Background and aims: Patients with Charcot neuroarthropathy (CN), display a paradoxical coexistence of medial arterial calcification (MAC) and osteolysis, with the suggestion of a key role for RANKL/OPG signal modulation. We aimed to study the potential mechanisms of RANKL/OPG-mediated vascular calcification in CN.
Materials and methods: Serum was obtained from 12 patients with acute CN, 10 patients with diabetes and 5 non-diabetic controls. Arterial segments were obtained from patients undergoing lower limb amputation and were fixed, sectioned and stained with Alizarin red and primary human RANK-L antibody. Human vascular smooth muscle cells (VSMCs) were explanted from the same arterial segments for subsequent cell culture experiments.
Results: Using Bioplex multi-array technology and ELISA bioassays, we demonstrated: i), higher serum OPG (8.2±2.7 vs 7.7±3.3 vs 4.2±0.4pM, p=0.031); ii), higher RANKL/OPG ratio (36.8±43.1 vs 5.2±4.9 vs 4.6±3.1 pM/pM, p= 0.033); iii), higher inflammatory cytokines IL-8 (p<0.0001) and G-CSF (p=0.002); and iv), a trend towards higher RANKL (0.32±0.42 vs 0.04±0.05 vs 0.02±0.01pM, p=0.054) in CN compared to diabetic and non-diabetic controls respectively. Cultured VSMCs displayed accelerated osteoblastic differentiation confirmed by Alkaline phosphatase activity (μM phosphate/mg protein/min) in the presence of serum from CN patients(49.9±7.3μM) compared to diabetic serum (29.8±3.7μM, p=0.012), control serum (17.6±10.1, p=0.011) or osteogenic medium (OM) controls (15.3±5.4μM, p=0.003). Cultured VSMCs also displayed increased mineralisation after Alizarin red staining and dye elution in Charcot serum (OD units, 0.16±0.01, p=0.0003); diabetes serum (0.15±0.01, p=0.0004); and marginally higher in 'Healthy' serum (0.14±0.03, p=0.04) compared to OM controls (0.09±0.003). Mineralisation and differentiation of VSMCs induced by Charcot serum were significantly attenuated (p=0.018 and p=0.004 respectively) when co-incubated with OPG, the decoy receptor for RANKL signalling. Immunohistochemical analysis of arterial sections showed positive RANKL expression within the vicinity of MAC compared to control non-calcified sections.
Conclusion: These data demonstrate that in humans, RANKL/OPG signalling is modulated and implicated in MAC and in CN, thus suggesting that anti-RANKL therapy may be therapeutic in acute CN or could have potential preventative value in recurrent CN.

116

Role of osteoprotegerin (OPG) in predicting development of foot ulcer and loss of foot pulse in type 1 diabetic patients with and without diabetic nephropathy

M. Lajer[1], A. Jorsal[1], L. Tarnow[1], L.M. Rasmussen[2], H.-H. Parving[3,4], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, [2]Dep. of Biochemistry, Pharmacology and Genetics, University Hospital of Odense, [3]Dep. of Biochemical Endocrinology, Rigshospitalet, University Hospital of Copenhagen, [4]Faculty of Health Science, University of Aarhus, Denmark.

Background and aims: The bone-related peptide osteoprotegerin is produced by vascular cells and is involved in the process of vascular calcification previously shown to predict mortality and cardiovascular events. We investigated the predictive value of plasma OPG in relation to foot complications in patients with type 1 diabetes (T1DM) with and without diabetic nephropathy.
Materials and methods: Prospective observational follow-up study of 397 type 1 diabetic patients with overt diabetic nephropathy (243 men; age [mean ± SD] 42.1 ± 10.6 years, duration of diabetes 28.3 ± 9.9 years, GFR 67 ± 28 ml/min/1.73 m^2) and a control group of 176 patients with longstanding type 1 diabetes and persistent normoalbuminuria (105 men; age 42.6 ± 9.7 years, duration of diabetes 27.6 ± 8.3 years). p-OPG was measured by ELISA.
Results: During the 12 (0-15) years (median (range)) of follow-up, 107 (40%) with OPG levels above the median *vs.* 76 (27%) below developed a foot ulcer,

p=0.001. This corresponds to a hazard ratio (HR) of 1.7 [1.3-2.3] and covariate adjusted (sex, age, nephropathy status, smoking, HbA_{1c}, systolic BP, eGFR, and CRP) HR 1.5 [1.0-2.1], p=0.04. Furthermore, 42 (16%) patients with higher OPG *vs.* 15 (5%) with lower lost foot pulse, adj. HR 2.2 [1.0-4.6], p=0.04. Similarly, 51 (18%) with higher OPG levels *vs*. 21 (7%) with lower had vascular surgery or amputation performed, HR 2.9 [1.7-5.0], p<0.001, however after adjustment this was no longer significant (p=0.53). In contrast, OPG levels were not related to loss of vibration perception or development of a Charcot foot, (p=0.11 and 0.27, respectively).
Conclusion: OPG is elevated in T1DM patients who developed a foot ulcer, lost foot pulse or had vascular surgery or amputation performed during follow-up. Furthermore, higher OPG levels remained an independent predictor of development of foot ulcer and lost foot pulse when adjusting for covariates.

The diabetic foot in Germany: analysis of quality in specialised diabetic footcare centres
R. Lobmann[1], E. Müller[2], C. Gröne[3], J. Kersken[3];
[1]Endocrinology, Diabetes and Geriatrics, Stuttgart General Hospital and Medical School, [2]General Practitioner and Diabetologist, Bernkastel-Kues, [3]Mathias-Spital und Jakobi-Hospital, Rheine, Germany.

Background and aims: The German Working Group on the Diabetic Foot developed certification requirements for diabetic foot centres. These certification requirements established procedures by which specialised centres for the treatment of the diabetic foot syndrome could verify their management quality. In addition, this certification fulfils the demands of the 2006 IDF Global Guideline for Type 2 Diabetes. The aim was to establish comparable diabetic foot centers with clearly defined treatment structures.
Materials and methods: Conditions for the certification are quality parameters of the facility's structure, treatment procedures and patient outcomes. Structural quality was based on the qualifications of staff, the facility's spatial conditions and a minimum provision of equipment. Staff members of certified centres must visit each other. Also assessed are the application of available guidelines and documentation systems, the establishment of a multidisciplinary team approach between the facility's staff and other experts involved. For the evaluation, each centre documented 30 consecutively seen individuals with diabetic foot lesions. An evaluation of the outcomes was performed 6 months after the initial presentation. All parameters are checked, presented and benchmarked in an open session of the working group.
Results: Data from 428 certified and re-certified centres are presented and a total of 12606 individuals were evaluated. At the 6-month follow-up assessment more than half of the lesions were completely healed (58%). The results of the evaluation indicate a low level of major (above-ankle) amputations compared with the expected amputation rates in Germany (nearly 10-15%).

Data given in %	Major-Amputation	Minor-Amputation	died
2005	3,9	19	4,6
2006	3,9	24	5,4
2007	3,6	20,1	5,1
2008	2,9	18,8	4,7
2009	2,7	16,7	2,9

Conclusion: These data represent the first analyses of the treatment outcomes of diabetic foot lesions in specialised centers in Germany over a time period of 5 Years. The data reflect a lower rate of major and minor amputations in specialist centres compared with the available epidemiological data for Germany as a whole. This analysis presents the first German data collected using defined standards that include amputation rate and mortality in the treatment of the diabetic foot in specialist centres. The established structures are appropriate to show consistent low rates of amputations over several years.

Acute antimicrobial effect of maggot therapy on diabetic foot ulcer infection as a basis for identification of antimicrobial peptides from maggots
R. Bem[1], A. Jirkovská[1], V. Fejfarová[1], M. Dubský[1], J. Skibová[1], V. Čeřovský[2];
[1]Diabetes Centre, Institute for Clinical and Experimental Medicine, [2]Institute of Organic Chemistry and Biochemistry, Academy of Sciences, Prague, Czech Republic.

Background and aims: The treatment of infected diabetic foot ulcers (DFU) is often complicated by emergence of antibiotic resistance; maggot debridement therapy (MDT) may be helpful in overcoming this problem. Antimicrobial effect of MDT and stimulation of immune response were proven in vitro. The aim of our study was to assess the antimicrobial effect of MDT on different strains of bacteria in a 5-year cohort of patients with infected DFU as a basis for identification of antimicrobial peptides from maggots.
Materials and methods: 91 patients with infected DFU treated in our diabetic foot clinic were enrolled in the present study between January 2005 and February 2010. Sterile free-range larvae of the green bottle fly Lucilia sericata were applied to the ulcers for 3-5 days (5-10 larvae per cm^2). Swabs or tissue samples were taken from deep structures of the wound after debridement. Specimens for culture were obtained immediately before and after MDT; control specimens were taken 10 (±3) days after the end of MDT. The individual bacterial species in positive swabs were determined by standard microbiological methods and microorganisms were categorized by Gram staining. MRSA was identified according to positive test for mec gene. High-performance liquid chromatography, mass spectrometry and Edman degradation were used for identification and isolation of antimicrobial peptides.
Results: The mean duration of MDT was 3.6±0.4 days. There was a significant elimination of majority of bacteria immediately after MDT: MRSA (21/91 vs. 5/91; p<0.001], Enterococcus sp. (36/91 vs. 15/91; p<0.001), Staphylococcus coagulase negative (21/91 vs. 7/91; p<0.001), Streptococcus sp. (6/91 vs. 0/91; p<0.001), Escherichia coli (13/91 vs. 5/91; p<0.02), Proteus sp. (13/91 vs. 5/91; p<0.01) and Klebsiella sp. (12/91 vs. 5/91; p<0.01). Antimicrobial effect persisted 10±3 days after cessation of MDT for all these strains of bacteria (all p<0.02). MDT was ineffective against Pseudomonas sp. (12/91 vs. 9/91; NS) and Acinetobacter sp. (6/91 vs. 4/91; NS). Antimicrobial peptide named lucifensin was identified from maggots after MDT of infected DFU and the primary sequence of this peptide was determined. In vitro, lucifensin was effective against Staphylococcus aureus PS 3A, PS 77, methicilin-resistant Staphylococcus aureus, Baccilus subtilis, Rhodococcus sp., but was ineffective against Esherichia colli and Pseudomonas aeruginosa. There was some correspondence between in vitro assessed antimicrobial effect of lucifensin and clinical effect of MDT.
Conclusion: Our study demonstrated that MDT acutely eliminated most of the Gram-positive including MRSA and Gram-negative strains in patients with infected DFU, but was ineffective against Pseudomonas sp. and Acinetobacter sp. The insect defensin designated lucifensin was isolated from maggots as a promising antimicrobial peptide.

A double blind randomised controlled trial of the efficacy of soluble beta-1,3/1,6-glucan in the management of chronic foot ulcers in diabetes
W.J. Jeffcoate[1], P.E. Price[2], L. Mudge[2], B. Olaussen[3], F.L. Game[1];
[1]Diabetes and Endocrinology, Nottingham University Hospitals Trust, [2]School of Health Care Studies, Cardiff University, United Kingdom, [3]Clinical Development, Biotec Pharmacon ASA, Tromso, Norway.

Background and aims: Beta-glucans from a variety of non-animal sources have been shown to have immuno-modulatory effects in animals and humans, partly by being recognised by the Dectin-1 receptor and partly by a specific interaction with complement receptor 3 - both of which are present on mammalian phagocytic cells, including neutrophils and macrophages. It is therefore possible that the administration of a beta-glucan such as soluble beta-1,3/1,6-glucan (SBG) might improve the healing of chronic wounds in diabetes through such an action. Since an earlier small open label pilot study and a double blind phase II study of SBG had suggested benefit, this trial was designed as a Phase III study.
Materials and methods: Patients with diabetes and full-thickness foot ulcers present for >4 weeks but less than 2 years, and of area between 25mm^2 and 500 mm^2, were randomised 1:1 to have either 2% aqueous SBG applied or

matching methyl cellulose placebo applied to their wounds on two or more occasions each week for 8 weeks. Those with active infection, without palpable foot pulses or with ABPI <0.7 were excluded. The primary outcome measure was healing within 8 weeks. Secondary outcomes included time to healing, breakdown of healed ulcers within 12 weeks, change in ulcer area, safety, patient well-being and satisfaction (EQ-5D, Cardiff Wound Impact Schedule).
Results: 122 patients (mean age 58.5y; 76.2% male) in 10 UK centres were randomised with 67 (54.9%) in the SBG group; the demographic and baseline characteristics of the two groups were comparable. Eight (3 SBG, 5 placebo) withdrew because of adverse event (5), death (1) or protocol violation (2). There was no difference in numbers healing within 8 weeks in the two groups (31.3% SBG versus 32.7% placebo; ITT p=0.87 CMH test). There was similarly no difference in time to healing in those that healed (ITT p=0.84, stratified log rank), or in change in ulcer area (ANCOVA p=0.45). There was no difference in change in local pain, or in EQ-5D and CWIS scores. 17.9% ulcers recurred within 12 weeks of complete healing, but there was no difference between groups (p=0.062 CMH). The majority of adverse events were mild or moderate in severity and unrelated to treatment.
Conclusion: We were unable to confirm the superiority of SBG versus placebo in terms of both primary and secondary endpoints in this study.

Comparison of healing of ischaemic diabetic foot ulcers after stem cell therapy or percutaneous transluminal angioplasty
M. Dubský[1], A. Jirkovská[1], R. Bem[1], L. Pagacova[1], V. Fejfarová[1], J. Skibova[1], M. Varga[1], E. Sykova[2];
[1]Institute for Clinical and Experimental Medicine, [2]Institute for Experimental Medicine, Prague, Czech Republic.

Background and aims: Critical limb ischaemia (CLI) is an important prognostic factor for ulcer healing in patients with diabetic foot ulcers (DFU) and often leads to amputations. Treatment of CLI in diabetic patients is generally difficult. Autologous stem cell therapy is a new therapeutic method for patients with CLI while the standard therapy remains percutaneous transluminal angioplasty (PTA) or peripheral vascular by-pass. The aim of our study was to compare healing of DFU in patients treated by stem cell therapy and PTA.
Materials and methods: Ten patients treated by stem cells at our foot clinic between January 2008 and October 2009 were included into the study (SCT group). All patients were diagnosed of CLI (defined by transcutaneous oxygen tension [$TcPO_2$] < 30 mm Hg), ulcer size was between 0.5 and 7 cm^2 with Texas classification 1C and 2C and no signs of acute infection. Stem cell therapy was indicated in patients with persisting ischaemia after standard revascularization. Autologous stem cells were obtained from bone marrow or peripheral blood after stimulation by growth factor and applied into muscles of affected lower limb. Ten patients from our foot clinic with the same inclusion criteria treated by angioplasty (PTA group) during the same period were included into the control group. They did not significantly differ from SCT group in mean age (62 ± 10 vs. 64 ± 8.5 years), gender (80 % vs. 70 % men), glycated hemoglobin (7.4 ± 0.8 vs. 7.6 ± 1.2 %) and mean diabetes duration (25 ± 11 vs. 20 ± 7.1 years). All patients were treated by standard podiatric methods. Area defect reduction was assessed after 3 and 6 months and time to full healing was evaluated 6 months after stem cell therapy or PTA.
Results: There was no significant difference in defect area (2.6 ± 1.5 vs. 2.7 ± 2.5 cm^2) and $TcPO_2$ (16.3 vs. 14.3 mm Hg) between both groups before the treatment. Area defect reduction was significantly faster in SCT group in comparison with PTA group after 3 months (20 ± 89.8 vs. 84.1 ± 30.3 %, p = 0.05); reduction after 6 months was not significantly different (38.1 ± 109.4 vs. 93.2 ± 13.3 %, NS). Six months after the therapy were healed 6/10 patients in both groups, but time to full healing was significantly shorter in SCT group (65.8 ± 20.1 vs. 126 ± 39 days, p = 0.016).
Conclusion: Our study showed faster healing of DFU after stem cell therapy than after PTA in patients with CLI and the same effect on healed patients after 6 months. Autologous stem cell therapy is a promising alternative for treatment of severe ischemia and DFU, but randomized controlled studies are required to confirm these results.

Selective elevation of insulin in the head suppresses hepatic glucoregulatory gene expression and net hepatic glycogenolysis in the conscious dog
C. Ramnanan[1], P.E. Williams[2], B. Farmer[1], D. Neal[1], W. Snead[1], A.D. Cherrington[1], D. Edgerton[1];
[1]Molecular Physiology and Biophysics, [2]Surgical Research, Vanderbilt University Medical Center, Nashville, USA.

Background and aims: Studies in the rodent have demonstrated that hypothalamic insulin signaling can play a role in controlling hepatic glucose production (HGP). However, we previously found in the dog that blockade of insulin signaling in the brain did not impair the suppression of HGP during a physiological elevation of insulin throughout the body. Thus, brain insulin signaling may not regulate HGP in non-rodent species with lower basal HGP, or alternatively, the effect of hepatic hyperinsulinemia may mask the subtle effects of brain insulin action. To determine the degree to which insulin action in the brain might contribute to inhibition of HGP in the presence of basal insulin and glucagon levels in the dog, insulin was selectively elevated in the blood perfusing the brain.
Materials and methods: Dogs underwent head (carotid and vertebral artery; jugular vein) and liver (femoral artery; portal and hepatic vein) catheterization and a cannula was inserted into the 3rd ventricle (ICV). On the day of the study, at -150 min [3-^{3}H]glucose and somatostatin (to inhibit pancreatic hormone secretion) were infused into a peripheral vein and glucagon and insulin were infused intraportally at basal rates. Following a basal sampling period (-30 to 0 min), artificial cerebrospinal fluid (aCSF; n=7) or the PI3K inhibitor LY29004 (to block brain insulin action; LY; n=8) was infused ICV (0 to 300 min). From 60 to 300 min, the liver insulin level remained clamped at basal while plasma insulin was selectively increased (10-fold) in the head by infusion of the hormone into the carotid and vertebral arteries, coincident with a cessation of portal insulin infusion. Intralipid, heparin and glucose were infused as required to clamp NEFA and glucose at basal.
Results: In both groups head insulin (jugular) increased 10-fold, arterial insulin increased 2-fold, and insulin at the liver remained basal. Glucose, glucagon and NEFA remained at basal levels. The change in net hepatic glucose balance between basal and the last hour in the LY and aCSF groups, respectively, was -0.09±0.12 and -0.58±0.27 mg/kg/min (P=0.05). The change in endogenous glucose Ra was -0.17±0.12 and -0.35±0.12 mg/kg/min, respectively. Net hepatic glycogenolytic (NHGLY) and gluconeogenic flux (GNG) were estimated using net liver balance. Delta NHGLY was -0.15±0.07 and -0.63±0.23 mg/kg/min (P<0.05) in the two groups, respectively, while delta GNG was 0.06±0.11 and 0.00±0.08 mg/kg/min. Liver P-Akt was basal in both groups at the end of the study, while hypothalamic P-Akt was basal in LY but had increased 2-fold in aCSF (P<0.05). Likewise, hepatic P-STAT3, reported to be increased by brain insulin signaling, was basal in LY but had increased 40% in aCSF (P<0.05). Liver PEPCK gene expression was reduced by 50% when insulin was selectively elevated in the head.
Conclusion: In the absence of an increase in insulin's direct hepatic effects, insulin signaling in the brain affected gene expression in the liver in a large animal model. HGP tended to be reduced although the effect was small, did not become significant until 2.5 h, and was due to inhibition of net hepatic glycogenolysis. It would appear that the rapid decrease in HGP which normally occurs in response to an increase in insulin secretion in vivo is unrelated to brain insulin signaling.

MCP-1 and chemerin are involved in the regulation of anandamide secretion by human skeletal muscle cells
K. Eckardt[1], M. Lehtonen[2], B. Platzbecker[1], A. Schober[1], J. Eckel[1];
[1]Inst. of Clin. Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, Germany, [2]Dep. of Pharm. Chemistry, University of Kuopio, Finland.

Background and aims: Obesity is one of the major components of the metabolic syndrome and associated with increased adipose tissue mass, which is characterised by an altered secretion profile. It has been shown that be-

sides other factors the levels of proinflammatory cytokines like MCP-1 and chemerin are elevated, and their implication in the induction of insulin resistance in skeletal muscle could be demonstrated. In addition, obesity is associated with a dysregulation of the endocannabinoid system leading to elevated plasma levels of anandamide (AEA) and 2-arachidonoylglycerol (2-AG) as well as decreased expression and activity of the AEA-degrading enzyme fatty acid amide hydrolase (FAAH). Previously, we could show that AEA is involved in the induction of skeletal muscle insulin resistance via enhanced IRS-1(Ser307) phosphorylation. Aim of the present study was to investigate whether skeletal muscle cells themselves are able to produce endocannabinoids and whether their secretion is regulated by selected cytokines.
Materials and methods: Differentiated primary human skeletal muscle cells (SkM) were incubated with 0.5 µg/ml chemerin and 2 ng/ml MCP-1, respectively. Medium was collected after 24 h, endocannabinoids were extracted and analysed by liquid chromatography/mass spectrometry. Additionally, RNA was prepared after 8 h or 24 h incubation and used for qRT-PCR to study the expression of FAAH and the AEA-synthesizing enzyme N-acylphosphatidylethanolamine-specific phospholipase D (NAPE-PLD).
Results: In media obtained from 3 different SkM donors we were able to detect AEA and 2-AG as well as palmitoyl ethanolamide (PEA) and oleoyl ethanolamide (OEA). The concentration in media from untreated cells was 1.75±0.08 pmol/l for AEA, 260.06±35.99 pmol/l for 2-AG, 6.38±2.58 pmol/l for PEA and 3.09±0.32 pmol/l for OEA. Stimulation of SkM with MCP-1 and chemerin for 24 h led to a significant increase of AEA, while for 2-AG, PEA, and OEA no significant changes were observed. MCP-1 treatment resulted in a 1.3-fold and chemerin treatment in a 1.8-fold increase of AEA concentration (n=3). The analysis of NAPE-PLD and FAAH expression showed that after 8 h incubation with MCP-1 the expression of NAPE-PLD was increased by ~15% and with chemerin by ~20%, while no change in FAAH expression was observed. However, after 24 h the expression of FAAH was downregulated by MCP-1 (~16%) and chemerin (~26%), while the expression of NAPE-PLD was at the level of untreated controls (n=3).
Conclusion: To the best of our knowledge, these results demonstrate for the first time the ability of human skeletal muscle cells to produce and secrete endocannabinoids such as AEA and 2-AG. In addition, we could prove that the proinflammatory cytokines MCP-1 and chemerin are involved in the regulation of AEA synthesis by causing an increase of AEA level. Part of this regulation includes changes of NAPE-PLD and FAAH expression. In summary, our data link MCP-1 and chemerin, which are known to induce skeletal muscle insulin resistance by themselves, to the endocannabinoid system and AEA, which also has been shown to play a role in the induction of skeletal muscle insulin resistance. In states of obesity, which are characterised by elevated levels of proinflammatory cytokines and AEA, the influence of MCP-1 and chemerin on AEA synthesis in muscle tissue may thus lead to further impairment of insulin sensitivity.

Secreted adipocyte fatty acid binding protein (FABP4) forms the molecular basis of the adipo-insular axis
L.E. Wu, D.E. James, J. Cantley;
Diabetes and Obesity Program, Garvan Institute of Medical Research, Darlinghurst, Australia.

Background and aims: Obesity is closely linked with increased insulin levels and β-cell mass. Obesity may be accompanied by adipose tissue hypoxia, which occurs when the rate of adipose tissue expansion exceeds the rate of required angiogenesis, leading to areas that are insufficiently vascularised and consequently hypoxic. We hypothesised the link between obesity and insulin levels to be a result of an inter-organ communication between hypoxic adipose tissue and the β cell, which may involve a secretory component.
Materials and methods: To assess the effects of adipocyte conditioned media on β-cell function, 3T3-L1 adipocytes were incubated in serum free culture media (RPMI1640) under atmospheric or 1% O2 concentrations. Conditioned media was dialysed and concentrated against a 10 kDa filter to remove small non-protein molecules. Dialysed conditioned media was diluted with 10% foetal calf serum and used to treat islets isolated from mouse pancreas for 24 hr. Glucose stimulated insulin secretion from islets was subsequently assayed. A stable isotope labelling of amino acids in cell culture (SILAC) quantitative mass spectrometry screen was performed to identify hypoxia regulated adipocyte secretory proteins.
Results: Conditioned media from hypoxic, but not normoxic control 3T3-L1 adipocytes led to an increase in glucose stimulated insulin secretion of 70% (412.7 ± 83.03 vs. 753.5 ± 108.6 pg insulin / islet / hr, p<0.05). A quantitative mass spectrometry screen led to identification of the adipocyte fatty acid binding protein FABP4 as a hypoxia responsive adipocyte secretory protein. Western blotting and ELISA data confirmed increased secretion of FABP4 from adipocytes into conditioned media during hypoxia (146.9 ± 16.64 vs. 1166 ± 61.18 ng / ml FABP4, p<0.0001). Serum concentrations of FABP4 were raised in high fat fed mice, along with circulating insulin concentrations (chow fed 259.9 ± 67.05 vs. high fat fed 804.8 ± 173.7 ng / ml serum FABP4, p<0.05; 1.397±0.470 vs. 3.205±0.549 ng / ml serum insulin, p<0.05). In vitro treatment of islets with physiologically relevant concentrations of recombinant FABP4 pre-incubated with linoleate but not palmitate enhanced glucose stimulated insulin secretion to a degree similar to hypoxic adipocyte conditioned media (535.4 ± 32.32 vs. 947.0 ± 134.5 pg insulin / hr, p<0.05). Hypoxia inhibits mitochondrial function, and treatment of adipocytes with the mitochondrial poisons DNP and oligomycin also stimulated FABP4 secretion. Treatment of adipocytes with insulin during hypoxia reduces FABP4 secretion. Removal of glucose from media and substitution with pyruvate reverses the inhibition of secretion during hypoxia by insulin, indicating that the primary role of FABP4 secretion is to alleviate energy crisis by increasing glucose uptake into fat through increased insulin secretion.
Conclusion: Taken together, these data are indicative of an adipo-insular axis mediated by FABP4, which functions to coordinate insulin secretion and glucose uptake in response to the prevailing needs of adipose tissue.

124

Interleukin-6 as a key mediator of metabolic adaptation to fasting
S. Wueest[1,2], H. Ellingsgaard[3,2], E.J. Schoenle[1], D. Konrad[1,2];
[1]Endocrinology/Diabetology University Children's Hospital Zurich, [2]Zurich Center for Integrative Human Physiology, University of Zurich, [3]Division of Endocrinology, Diabetes & Nutrition, University Hospital Zurich, Switzerland.

Background and aims: Fasting leads to increased production of ketone bodies from non-esterified fatty acids (NEFA) liberated from white adipose tissue. However, it is not known whether interleukin-6 (IL-6) contributes to this fasting-induced lipolysis. Thus, the aim of the present study was to analyze whether IL-6 contributes to the metabolic switch from carbohydrate to fat oxidation (metabolic flexibility) provoked by food deprivation (fasting) in lean mice, and if yes, whether this metabolic switch is maintained in obesity and insulin resistance.
Materials and methods: Experiments were performed in C57BL/6J mice fed regular chow or high fat diet (HFD) for 8 weeks and in IL-6 KO mice. Mice were fed ad libitum or fasted for 24 hours and blood was sampled after 0, 6, 12 and 24 hours. Body weight as well as blood glucose and ketone levels were determined. In addition, plasma IL-6, leptin, insulin and NEFA levels were measured and IL-6 mRNA levels were analysed.
Results: The transcription of IL-6 was significantly induced in skeletal muscle but not in white adipose tissue in chow-fed C57BL/6J mice after 6 hours of food withdrawal. Concomitantly, circulating IL-6 levels increased by 3-fold (p<0.05) without changes in plasma insulin levels. Moreover, increased circulating IL-6 levels upon 6 hours of fasting were accompanied by elevated ketone levels (0.50±0.04 mmol/l in fasted vs 0.25±0.04 mmol/l fed mice; p<0.01), an effect that was blunted in IL-6 KO mice (0.48±0.09 mmol/l in WT vs 0.24±0.01 mmol/l in IL-6 KO mice; p<0.05) and chow-fed mice injected with neutralizing IL-6 antibody (0.65±0.03 mmol/l in IgG vs 0.38±0.05 mmol/l in IL-6 nAB injected mice; p<0.001). In addition, HFD-fed mice showed no increased circulating IL-6 levels upon fasting, paralleled by a blunted increase in ketone bodies in the first 6 hours of food withdrawal compared to chow-fed mice (0.37±0.04 mmol/l in chow-fed vs 0.15±0.04 mmol/l in HFD-fed mice; p<0.01).
Conclusion: IL-6 contributes to fasting-induced lipolysis and metabolic flexibility.

New adipokines identified as downstream targets for adiponectin: lessons from adiponectin-overexpressing or deficient-mice
Q. Ge, L. Rycken, L. Noël, S.M. Brichard;
Unité d'Endocrinologie et Métabolisme, l'Université Catholique de Louvain, Bruxelles, Belgium.

Background and aims: Adipokines play a central role in the pathogenesis of the metabolic syndrome. Adiponectin (ApN) is a master regulator of immune

and fuel homeostasis. Identifying downstream adipokines targeted by ApN may help in understanding its action. We have generated transgenic mice allowing persistent and moderate overexpression of ApN (ApN-Overex) specifically in white adipose tissue (AT)(by using the aP2 promoter). We took advantage of this model to unravel the adipokine secretion profile triggered by ApN in AT. We also examine whether a reverse profile occurred in ApN-knockout (ApN-KO) mice.
Materials and methods: To investigate the early and specific effects of ApN, mice were studied at 10 wks of age (before any changes in adiposity or in circulating glucose/lipids). AT was fractionated into adipocytes and stromal-vascular cells (SVC), which were cultured for 8 h. Medium was screened by cytokine antibody arrays allowing the detection of 144 cytokines. Secretion of relevant adipokines was quantified by ELISA and gene expression by RTQ-PCR. NF-κB activity was measured by ELISA and Jun N-terminal kinase (JNK) phosphorylation by western blot.
Results: Profiling of secretory products by antibody arrays showed that ~10 cytokines from each cellular fraction roughly differed between ApN-Overex mice and wild type (WT) mice. These adipokines were quantified by ELISA. When compared to WT mice, the secretion of 3 pro-inflammatory factors (IL-17B, IL-21, TNF-α) and 3 hematopoietic growth factors (GF)(Thrombopoietin, TPO; Granulocyte-, GCSF and granulocyte macrophage-stimulating GF, GMCSF) was reduced in adipocytes of ApN-Overex mice. In SVC of these mice, besides the hematopoietic GFs, the secretion of another GF (vascular endothelial GF receptor 1, VEGFR1), 2 chemokines (RANTES, ICAM-1) and 2 pro-inflammatory factors (IL-6, IL-12p70) was reduced as well. Only one cytokine was oversecreted by SVC of ApN-Overex mice: interleukin-1 receptor 4 (IL-1R4) that exhibits anti-inflammatory properties. Most of these changes in secretion were due to corresponding changes in mRNAs. To investigate whether these changes were specifically induced by ApN, we searched for a reverse profile of adipokine expression in mice lacking ApN. TPO gene expression was increased in adipocytes of ApN-KO mice, and the expression of VEGFR1, IL-12p70 and ICAM-1 was augmented in SVC of these mice. Concomitantly, IL-1R4 expression was reduced in SVC of ApN-KO mice. We next investigated the molecular pathways underlying these inflammatory changes. NF-κB activity was remarkably reduced in AT of ApN-Overex mice, while JNK phosphorylation was unaffected.
Conclusion: ApN regulates in vivo the secretion of downstream adipokines, thereby inducing a shift of the immune balance in both adipocytes and SVC toward a less inflammatory phenotype. These downstream adipokines may be new therapeutic targets for the management of the metabolic syndrome.

126

Bradykinin 1 receptor inhibition improves glucose tolerance and reduces adipose tissue inflammation in high-fat diet fed mice

M. Sörhede Winzell, A. Ahnmark, K. Lundmark, L. William-Olsson, J. Oscarsson, M. Strömstedt, D. Lindén;
Diabetes & Obesity, AstraZeneca R&D, Mölndal, Sweden.

Background and aims: Kinins are proinflammatory peptides which are involved in the control of blood pressure, inflammation and pain. Recently, it was demonstrated that bradykinin 1 receptor (B1R) deficient mice had reduced fasting plasma glucose and insulin levels and were protected against high-fat diet (HFD) induced obesity. It is however not shown whether pharmacological inhibition of B1R affects glucose tolerance and insulin sensitivity. The aim of this study was to establish whether B1R antagonism could improve glycemia and glucose tolerance in obese, insulin resistant mice. Furthermore, the effect of B1R antagonism on inflammatory markers in adipose tissue was investigated.
Materials and methods: Female C57BL/6J mice were fed a HFD (60%fat) for up to 20 weeks. Thereafter, the mice were administered subcutaneously, twice daily for 12 days with a B1R antagonist (SSR240612, Sanofi-Avensis R&D, 10mg/kg/day). Control mice received vehicle only (5% mannitol). Body weight and food intake were registered every second day. After 7 days treatment, glucose tolerance was estimated in an oral glucose tolerance test (OGTT; 2 g/kg). At termination, adipose tissue samples were collected and the expression of inflammatory markers was analyzed using real time PCR.
Results: After feeding the mice with HFD, basal glucose was elevated (9.1±0.1 vs. 7.8±0.1 mM, $p<0.01$) as well as insulin (1.8±0.3 vs. 0.37±0.06 ng/ml, $p<0.001$) compared to lean, normal diet (ND) fed mice, demonstrating significantly impaired insulin sensitivity in the HFD fed mice. One week treatment of HFD fed mice with the B1R antagonist restored basal glucose levels to 7.9±0.2 mM ($p<0.01$) and reduced insulin levels to 0.91±0.1 ng/ml ($p<0.001$) compared to HFD fed control mice, suggesting improved insulin sensitivity in the B1R antagonist treated mice. Body weight was significantly reduced during B1R antagonism ($p<0.001$), where treated mice lost 11% of their body weight compared to HFD fed control mice during the 12 days treatment period. Food intake was slightly reduced during the second week of treatment, although the body weight loss was apparent earlier than any effects on food intake was observed, suggesting other mechanisms than reduced food intake to be responsible for the weight loss. The OGTT demonstrated improved glucose tolerance with reduced glucose and insulin excursions after B1R inhibition. In the HFD fed mice the expression levels of several markers of inflammation were increased in perigaonadal adipose tissue compared to ND fed mice. B1R antagonism resulted in reduced mRNA expression of MCP-1, TNFα, IL-6 and IL-1β in adipose tissue.
Conclusion: B1R antagonism in obese, insulin resistant mice resulted in improved glycemia, reduced basal insulin levels and improved glucose tolerance. These findings, in association with reduced expression of adipocytokines, demonstrate that inhibition of B1R may be a novel treatment strategy for type 2 diabetes.

OP 22 Making and replacing islet beta cells

127

Effective revascularisation and enhancement of islet engraftment by cotransplantation of islets with endothelial progenitor cells

S. Kang, H.S. Park, H.S. Jung, K.S. Park;
Snuh, Seoul, Republic of Korea.

Background and aims: Islet transplantation is an emerging therapeutic option for type 1 diabetic patients. However, it has many obstacles, one of which is impaired revascularization in transplanted islets leading to islet loss. In contrast to solid organ transplantation where the organ is nourished by large vessel anastomosis, avascular islets suffer from hypoxia and malnutrition for a long time as a consequence of absence of effective blood supply, which results in continuous islet loss and ultimately, only a short period of effective graft function. Endothelial progenitor cells (EPCs) are well known to induce neovascularization in diverse ischemic tissues. Here we aimed to increase islet engraftment by cotransplantation of islets with EPCs.
Materials and methods: Porcine islets were transplanted beneath the kidney capsule of athymic nude mice with or without human cord blood-derived EPCs (EPC group or islet only group, respectively). The transplanted β-cells, EPCs, and blood vessels from islets or host mouse were evaluated by insulin, UEA-1 lectin, and BS-1 lectin immunostaining, respectively. The islet function was followed for 4 weeks post-transplantation with random blood sugar level.
Results: The EPC group mice reached euglycemia (random blood sugar<200mg/dL) at 17 days after transplantation, whereas islet only group mice did not even though they showed improvement of glycemic control compared to diabetic sham control mice. The EPC group mice showed significant increase of body weight compared to the islet only group mice, while sham control diabetic mice continuously lost their weight, which finally lead to death around 28 days post-transplantation. In addition, compared to sham control group, both the islet only and EPC group showed detectable porcine insulin level with the fact that EPC group showed higher level of insulin at both fasting and at glucose challenge compared to the islet only group. At 28 days after transplantation, the kidney bearing transplanted islets were removed to evaluate whether euglycemia induction was by transplanted porcine islets themselves or by regeneration of remnant pancreatic islets in the host. After 7 days of nephrectomy, blood glucose levels of the EPC group reached approximately 500 mg/dL, suggesting that the transplanted islets contributed mainly to glycemic control. Immunostaining of the transplanted islets 5 weeks post-transplantation demonstrated that the islets from the EPC group were highly revascularized compared to those of the islet only group, which coincided with the higher β-cell mass in the EPC group. We also tracked the vasculature of transplanted islets at 3, 14, and 35 days post-transplantation to see the time course of vessel ingrowth into the transplanted islets. Compared to the islet only group, the EPC group showed much more blood vessel organization and branching at 3 days and a significant increase in the number and length of vessel ingrowth at 14 days post-transplantation. Importantly, this was associated with a time-dependent increase of insulin(+) areas in the transplanted islets and also, proliferating, Ki-67-insulin double-positive, regenerating β-cells, all of which were significantly increased in the EPC group than the islet only group.
Conclusion: Collectively, we concluded that cotransplantation of EPCs with islets induce better islet engraftment by enhancing graft revascularization and survival/regeneration of islets.

Pancreatic islets transplanted intraportally into the liver in mice have a substantially lower blood flow than native islets

J. Lau Börjesson[1], J. Henriksnäs[1], P.-O. Berggren[2], M. Köhler[2], P.-O. Carlsson[1];
[1]Department of Medical Cell Biology, Uppsala University, [2]The Rolf Luft Reserach Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Pancreatic islets are in the clinical setting transplanted intraportally into the liver, but with low long-term success rate. Engraftment of pancreatic islets in the liver has been difficult to study, since the islets virtually disappear out of sight and imaging techniques have too poor resolution for their study. However, experimental studies have indicated a low revascularization of islets at the intrahepatic site, and that ingrowing blood vessels are derived solely from the hepatic artery and not the portal vein. The aim of the present study was to establish a model and quantify the blood perfusion of intrahepatically transplanted islets. Islet vascular density and the contribution of donor blood vessels in the islet revascularization process were also determined.
Materials and methods: Pancreatic islets were isolated from transgenic YC-3.0 mice, which express the yellow chameleon protein 3.0 under the regulation of the β-actin and cytomegalovirus promoters. Islets from these mice have previously been shown to express enhanced yellow fluorescent protein, one part of the hybrid YC-3.0 protein, in all cells. The islets were transplanted intraportally selectively into the right liver lobe of recipient nude mice by temporary occlusion of the other tributaries of the portal vein at the time of islet infusion (200 islets). One month later, blood perfusion of the transplanted islets was determined by a fluorescent microsphere technique and compared to the blood perfusion of native YC-3.0 islets. The vascular density and relative contribution of recipient and donor blood vessels in islet revascularization was evaluated one month post-transplantation using islets expressing green fluorescent protein behind the Tie2 promoter (Tie2-GFP) for intraportal transplantation to nude mice.
Results: The blood flow in the YC-3.0 islets transplanted to the liver was 0.20 ± 0.1 ml/min/mg islet (n=10), which was markedly lower than the blood perfusion of native YC-3.0 islets (3.86 ± 0.54 ml/min/mg islet; n=6). The blood flow in the native islets of the transplanted nude mice was 3.54 ± 0.62 ml/min/mg islet (n=10). Vascular density in the intraportally transplanted islets was decreased, and very few donor endothelial cells could be observed incorporated in the new islet vascular system.
Conclusion: The blood perfusion of intrahepatically transplanted islets is less than 10% of that in native islets when investigated one month post-transplantation. Low numbers of donor blood vessels contribute to the revascularization at the intrahepatic site, which may at least partially explain their insufficient vascular engraftment.

Clinical and experimental pancreatic islet transplantation to striated muscle: Establishment of a vascular system similar to that in native islets

G. Christoffersson[1], J. Henriksnäs[1], L. Johansson[2], C. Rolny[3], H. Ahlström[2], J. Caballero-Corbalan[2], R. Segersvärd[4], J. Permert[4], O. Korsgren[2], P.-O. Carlsson[1,5], M. Phillipson[1];
[1]Department of Medical Cell Biology, Uppsala University, [2]Department of Oncology, Radiology and Clinical Immunology, Uppsala University, [3]Department of Genetics and Pathology, Uppsala University, [4]Department for Clinical Science, Intervention and Technology, Karolinska Institute, Stockholm, [5]Department of Medical Sciences, Uppsala University, Sweden.

Background and aims: Curing type 1 diabetes by transplanting pancreatic islets into the liver is associated with poor long-term outcome and graft failure at least partly due to inadequate graft revascularization. The aim of the current study was to evaluate striated muscle as a potential angiogenic site for islet transplantation.
Materials and methods: The current study presents a new experimental model which is found applicable to clinical islet transplantation. Islets were implanted into striated muscle where after intra-islet vascular density and blood flow were visualized with intravital and confocal microscopy in mice, and by magnetic resonance imaging in three auto-transplanted pancreatectomized patients. Mice were rendered neutropenic by repeated injections of Gr-1 antibody and diabetes was induced by alloxan treatment.
Results: Contrary to liver engrafted islets, islets transplanted to mouse muscle were revascularized with vessel densities and blood flow entirely comparable to islets within intact pancreas. Initiation of islet revascularization at the muscular site was dependent on neutrophils, and the function of islets transplanted to muscle was proven by curing diabetic mice. The experimental data were confirmed in auto-transplanted patients where higher plasma volumes were measured in islets engrafted in forearm muscle compared to adjacent muscle tissue through high-resolution magnetic resonance imaging.
Conclusion: This study presents a novel paradigm in islet transplantation whereby recruited neutrophils are crucial for the functionally restored intra-islet blood perfusion following transplantation to striated muscle under experimental and clinical situations.

Tracking mouse islet isografts and allografts using a novel magnetic resonance contrast agent, chitosan-coated superparamagnetic iron oxide nanoparticles

J.-H. Juang[1], C.-R. Shen[2], J.-J. Wang[3], C.-H. Kuo[4], Z.-T. Tsai[5], T.-C. Yen[5]; [1]Division of Endocrinology and Metabolism, Chang Gung University and Memorial Hospital, [2]Department and Graduate Institute of Medical Biotechnology and Laboratory Science, Chang Gung University, [3]Department of Medical Imaging and Radiological Sciences, Chang Gung University, [4]Department of Biological Science and Technology, National Chiao Tung University, [5]Molecular Imaging Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background and aims: Although only 10% of islet recipients maintain insulin independence, 80% of them are C-peptide positive at 5 years after transplantation. To better understand the fate of transplanted islets, a magnetic resonance (MR) imaging technique has been used to detect superparamagnetic iron oxide (SPIO)-labeled islet grafts. In this study, we utilized a novel MR contrast agent, chitosan-coated SPIO (CSPIO) nanoparticles, to monitor mouse islet isografts and allografts.
Materials and methods: Male C57BL/6 mice were used as donors and male inbred C57BL/6 (syngeneic) and Balb/c (allogenic) mice were used as recipients of islet transplantation. Mouse pancreas was digested by collagenase and islets were purified by density gradient. After being incubated with and without CSPIO (10 mg/ml), islets were examined under transmission electron microscope (TEM) and their insulin secretion was measured by static incubation and perifusion studies. Cytotoxicity was evaluated by fluorescein diacetate and propidium iodide staining for NIT-1, βTC and αTC1 cells. Three hundred islets were transplanted under left kidney capsule of each mouse. After transplantation, 3.0 Tesla MR imaging of the recipients was performed. At the end of study, the islet graft was removed for insulin and Prussian blue staining and TEM studies.
Results: At 8 hours after incubation of isolated islets with CSPIO, TEM showed CSPIO particles located in endocytotic vesicles of both α- and β-cells. The islets incubated overnight with and without CSPIO had comparable insulin responses to high glucose challenges. There was no increased death rates in NIT-1, βTC and αTC1 cells with increasing CSPIO iron concentrations up to 80 μg or incubation time up to 72 hours. At week 0, 1, 2, 3, 4, 5, 6, 8 after syngeneic transplantation, the grafts of CSPIO-labeled islets were visualized on MR scans as distinct hypointense spots homogeneously located at the upper pole of left kidney. Using the contralateral kidney as a reference, the MR signal intensity of CSPIO-labeled and control islet grafts was 81.9 ± 14.0% and 103.8 ± 15.4%, respectively (P=3.68297E-05). At 8 weeks after transplantation, the CSPIO-labeled islet graft was positive for insulin and iron staining. Under TEM, there were several electron dense clumps distributed in the cytoplasm of islets with intact ultrastructure. The electron energy-loss spectroscopy further demonstrated these clumps contained elementary iron. At day 3, 10, 17, 24, 31, 38 and 45 after allotransplantation, MR scans showed hypointense spots at the upper pole of left kidney gradually decreased in size. The histology of CSPIO-labeled islet grafts at day 10, 17, 24, 31, 38 and 45 showed insulin- and iron-staining co-localized in the same areas but the graft size decreased with time.
Conclusion: Our results indicate, after syngeneic and allo-transplantation, isolated mouse islets labeled with CSPIO nanoparticles can be effectively and safely imaged by using MR scanning.

Generation of pancreatic endocrine cells from human adult fibroblast-like limbal stem cells

C. Giordano[1], A. Criscimanna[1], G. Zito[1], A. Taddeo[1], P. Richiusa[1], M. Pitrone[1], D. Morreale[2], G. Lodato[2], G. Pizzolanti[1], R. Citarrella[1], A. Galluzzo[1]; [1]Section of Endocrinology, DOSAC, Endocrinology, [2]Dipartimento di Oculistica, Ophtalmology, Palermo, Italy.

Background and aims: Stem cells might provide unlimited supply of transplantable cells for β-cell replacement therapy in diabetes. The human limbus hosts epithelial stem cells - which sustain the continuous renewal of the cornea - and fibroblast-like stem cells (f-LSCs) - with apparent broader plasticity. The aim of this study was to isolate and characterize f-LSCs from human donors and to test their differentiation potential towards the pancreatic endocrine phenotype.
Materials and methods: f-LSCs were isolated from 14 limbal biopsies. f-LSCs were characterized by flow cytometry and qRT-PCR for the expression of pluripotent markers and self-renewal ability. We then developed a 4-step pancreatic differentiation protocol, lasting 14-16 days, by adding in a step-by-step way factors and supplements which are known to direct/support pancreatic differentiation, such as activin A, bFGF, B27, N2, nicotinamide and exendin-4. The expression of endodermal, pancreatic, islet and β-cell markers was assessed during differentiation by immunofluorescence, flow cytometry and western blot analysis. Presence of secretory granules was assessed by confocal and electron microscopy. f-LSC-derived cells were also investigated for the ability to secrete C-peptide in response to multiple secretory stimuli.
Results: FACS analysis of freshly digested limbal specimens showed significant expression of the pluripotent stem cell marker SSEA4 (mean ± SD: 65.2 ± 7.6%). After 24-48 hrs, the single cell suspension formed floating spherical aggregates ('limbospheres'), which eventually attached to the plastic surface, giving rise to highly proliferating f-LSCs. Adherent epithelial cells were also observed but f-LSCs progressively prevailed. Positivity for SSEA4 was higher in cultures obtained by re-plating limbospheres, which were devoid of epithelial cells (mean ± SD: 90.8 ± 9.6%). $SSEA4^+$ f-LSCs co-expressed Oct4, Sox2, c-Kit, TRA 1-60, TRA 1-81, ABCG2, Thy-1 and CD105. f-LSCs were negative for CD34, CD45, HLA-DR and for the limbal epithelial marker ΔNp63. Staining of CFSE-labelled $SSEA4^+$ f-LSCs showed that cells are characterized by asymmetrical division. f-LSCs treated with pancreatic differentiation protocol transitioned through a series of intermediates similar to those occurring during pancreatic development, as showed by sequential detection of endodermal, pancreatic, islet and β-cell markers (Sox17, FOXA2, Ngn3, PDX1, MafA, ISL-1, β2NeuroD, NKX6.1, Pax4, GLUT2 and glucokinase). From stage 3 cells progressively gathered in clusters resembling human islets. qRT-PCR, immunofluorescence and western blot analysis at the end of differentiation confirmed expression of islet hormones (c-peptide/proinsulin, insulin, glucagon, somatostatin, ghrelin and PP). Quantification of endocrine cells by flow cytometry showed 72.1 ± 5.3% positive cells for C-peptide/proinsulin, 10.6 ± 2.4% for glucagon and 8.2 ± 2.6% for somatostatin. Confocal and electron microscopy indicated presence of secretory granules. Differentiated cells also possessed the ability to secrete C-peptide in response to glucose, KCl and Tolbutamide.
Conclusion: f-LSCs might represent a novel source of autologous, transplantable, insulin-producing cells which could be tested for the reversal of diabetes.

Metabolic control in patients with type 1 diabetes after autologous peripheral stem cell transplantation (apbsct)

A. Milczarczyk[1], E. Snarski[2], W. Jędrzejczak[2], E. Franek[1]; [1]CSK MSWiA, [2]Medical University of Warsaw, Poland.

Background and aims: Type 1 diabetes mellitus is caused by autoimmunological process destroying pancreatic ß cells. APBSCT leads to modulation of immunological system (in terms of elimination of aggression against ß cells), what subsequently leads to alleviation of autoagressive process and to insulin independency.
Materials and methods: In 8 patients (4 female, 4 male, age 26.0±5.0) with newly diagnosed type 1 diabetes APBSCT was performed. Treatment consisted of 2-3 plasmaphereses, hematopoietic stem cell mobilization with cyclophosphamide ($2g/m^2$, on day -16) and G-CSF (10ug/kg from day -15), collection of at least 3 x 10^6/ kg CD34+ cells, conditioning with cyclophosphamide (50 mg/kg/day on days -5,-4,-3,-2 prior to transplant) and antithymocyte globulin (0,5mg/kg/day on day -5, 1,0 mg/kg/day on days -4,-3,-2,-1) followed by stem cells infusion.
In all patients FPG, HbA_1c, C-peptide fasting and after mixed meal, continuous glucose monitoring (CGM) and intravenous glucose tolerance test (IVGTT) 6 months after transplantation were performed. Control group comprised 6 patients (2 female, 4 male, age 26.2±3.1) in whom after diagnosis an intensive insulin therapy was initiated. In the control group CGM and IVGTT were not performed.
Results: Parameters of metabolic control were shown in table 1. All patients 6 months after APBSCT were insulin-free. HbA_1c and FPG were comparable to the control group, but higher C-peptide values were noted. Insulin concentrations in IVGTT were as follows: 8.1; 9.2; 9.0; 8.7; 9.2; 9.1; 9.0; 8.9; 8.6; 7.6; 7.3 uIU/l (basal 5.4uIU/l).
Conclusion: APBSCT seems to be a promising method of treatment of newly diagnosed type 1 diabetes.

Ctnnb1 gene expression is associated with impaired beta cell function of type 2 diabetic donors

V. D'Aleo[1], S. Del Guerra[1], G. Gualtierotti[1], F. Vistoli[2], U. Boggi[2], F. Filipponi[3], P. Marchetti[1], S. Del Prato[1], R. Lupi[4];
[1]Endocrinology and Metabolism, Metabolic Unit, University of Pisa, [2]Department of Oncology, Transplantation and Advanced Technologies in Medicine, University of Pisa, [3]Department of Liver Transplantation, Hepatology and Infectious Diseases, Azienda Ospedaliero-Universitaria Pisana, [4]Endocrinology and Kidney, Metabolic Unit, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy.

Background and aims: Common TCF7L2 genetic variants are associated with increased risk for development of type 2 diabetes (T2DM). Beta-catenin/TCF7L2-dependent Wnt signaling is involved in pancreas development, islet function, and insulin production and secretion. Nonetheless, no study has yet assessed Wnt signaling in human islets of T2DM patients. We have, therefore, examined the expression of Wnt pathway component beta-catenin (CTNNB1) in islets isolated from the pancreases of non-diabetic and T2DM individuals.
Materials and methods: Islets were prepared from the pancreas of 9 non-diabetic (CTRL) (5M/4F; age 60.25±13.7 yrs; 25.68±3.68 kg/m2) and 6 T2DM (2M/4F; 64.4±7.2 yrs; 27.20±2.65 kg/m2) multiorgan donors. Glucose-stimulated insulin release (static incubation), mRNA expression of beta-catenin, TCF7L2, and insulin (Real-time RT-PCR) were determined. In order to establish a cause-effect relationship, CTNNB1 and TCF7L2 gene expression were suppressed by siRNA in Ctrl and TCF7L2 overexpressed the by plasmid DNA in Ctrl islets.
Results: Glucose-stimulated insulin release was impaired in T2DM islets as compared to Ctrl (Stimulation Index: 1.34±0.32 vs. 3.59±1.72; p<0.05). Both CTNNB1 (0.03±0.01 vs. 0.09±0.03, p<0.001), and TCF7L2 mRNA expression (0.42±0.41 vs. 7.35±3.40, p<0.001) were higher in T2DM than in Ctrl islets. The two gene expressions were positively correlated (R2=0.508; p=0.0028) while they were negatively correlated with Stimulation Index (CTNNB1: R2=0.267, p=0.052; TCF7L2: R2=0.338, p=0.0231). CTNNB1 and TCF7L2 siRNA transfection of Ctrl islets transfected resulted in a significant reduction of respective gene expression (-72.1±6.9% and -32.8±6.1%, respectively), whereas the Stimulation Index increased (+43.7±14.1% and +37.2±17.3% for CTNNB1 and TCF7L2 silencing, respectively; both p<0.05 or less vs. Ctrl). Insulin gene expression was marked increased in siRNA CTNNB1 transfected islets (+36.46±13.3%), compared to the controls (p<0.001). Finally, TCF7L2 overexpression in non-diabetic islets (+55.7±16.3%) was associated with a significant increase of CTNNB1 gene expression (+67.5±17.9%, p<0.001).
Conclusion: CTNNB1 and TCF7L2 gene expression are increased in islets from T2DM isolated islets, and the expression is negatively correlated with impaired glucose-mediated insulin response. Moreover, modulation of TCF7L2 expression is associated with simultaneous changes in CTNNB1 expression and glucose-mediated insulin release. Our results support the hypothesis that 1) alterations of Wnt signaling occur in pancreatic islets of T2DM patients, and 2) TCF7L2 effects may be mediated via consensual changes in beta-catenin.

134

Risk genotypes, allele-specific expression and methylation status in human islets at the *KCNQ1* type 2 diabetes-susceptibility locus

M.E. Travers[1], M. Dekker Nitert[2], D.J.G. Mackay[3], C.M. Lindgren[4], L. Groop[2], A.L. Gloyn[1], M.I. McCarthy[1];
[1]OCDEM, University of Oxford, United Kingdom, [2]Lund University Diabetes Centre, Malmo, Sweden, [3]Southampton University School of Medicine, [4]WTCHG, University of Oxford, United Kingdom.

Background and aims: Though the number of Type 2 Diabetes (T2D) associated loci has increased rapidly, in relatively few cases have the mutational mechanisms through which they operate been enumerated. The *KCNQ1* locus harbours 2 independent clusters of variants associated with T2D risk and impaired insulin secretion, the SNPs with strongest association in European populations in each peak being rs231362 and rs163184. Whilst both signals are intronic, one maps directly over a non-coding RNA (*KCNQ1OT1)*, whose transcription is regulated by parent-of-origin specific methylation, and which is known to regulate transcription of several local cell-cycle repressors, including *CDKN1C,* itself implicated in islet-specific growth phenotypes. Associated SNPs at both signals confer T2D risk only when maternally inherited, implicating aberrant regulation of imprinted expression as the probable mutational mechanism. The aim of this study was to determine whether, in human islets, risk genotype status at *KCNQ1* has effects on DNA methylation, total gene expression and allele-specific expression consistent with this proposed mutational mechanism.
Materials and methods: DNA and RNA were extracted from 42 human islet samples of European origin. Associated SNPs in both signals (e.g. rs231362, rs163184) were genotyped (TaqMan), and methylation quantified (Bisulfite pyrosequencing). Total expression of *KCNQ1*, *KCNQ1OT1*, *KCNQ1DN*, *CDKN1C*, *PHLDA2*, *SLC22A18* and *SLC22A18AS* was determined by qRT-PCR. Allele-specific gene expression was assessed by qRT-PCR, differentiating alleles via coding variants, or (for *CDKN1C*) fragment size analysis using a 12bp exonic indel (del171APVA).
Results: All genotypes were in accordance with expected (HapMap CEPH) frequencies, and displayed no departure from Hardy-Weinberg equilibrium. We found no effective tagging SNP for del171APVA, its strongest LD relationship being with rs2237901 (r^2=0.59). With the exception of *KCNQ1DN*, all tested genes were quantifiably expressed in human islets. The clearest evidence of monoallelic expression was found for *CDKN1C*: without exception, samples heterozygous for del171APVA at the DNA level appeared homozygous at the cDNA level. However, we found no relationship between risk genotype and gene expression for any of the tested genes (p>0.05 in all cases). Risk genotype was correlated with methylation status at 2 sites located on the borders of *KCNQ1OT1*'s differentially methylated promoter region. At both *CTCF* and putative *ZAC* binding sites, methylation level increased with risk allele number. The effect was small (increases of 5.5% and 7.5% on top of 40% and 36% respectively) but significant (p=0.0004 for each).
Conclusion: We have performed the first assessment of the association between risk genotypes at the *KCNQ1* locus and regional effects on DNA methylation and gene expression (total and allele-specific) in human islets. We have shown monoallelic expression of *CDKN1C* in human islets and evidence that risk genotypes effect DNA methylation, but further work is required to demonstrate that these have consequences for regional gene expression. Our study demonstrates the complexity of translating association signals into mutational mechanisms.

Rare variants of the glucagon gene (GCG) associate with serum insulin and plasma glucagon release, type 2 diabetes, and measures of obesity

S.S. Torekov[1,2], L. Ma[3], I. Hainerova[4], J. Lebl[4], D.R. Witte[5], A. Linneberg[6], T. Jørgensen[6], A. Sandbaek[7], T. Lauritzen[7], O. Madsen[2], J. Wang[3], S. Madsbad[8], J.J. Holst[1], T. Hansen[2], O. Pedersen[2];
[1]Department of Biomedical Sciences, University of Copenhagen, [2]Hagedorn Research Institute, Gentofte, Denmark, [3]Beijing Genomics Institute at Shenzhen, China, [4]Charles University, Prague, Czech Republic, [5]Steno Diabetes Center, Gentofte, [6]Glostrup University Hospital, [7]University of Aarhus, [8]Hvidovre University Hospital, Denmark.

Background and aims: The glucagon gene (*GCG*) encodes several hormones crucial for energy metabolism: glucagon, oxyntomodulin, glucagon-like-peptide (GLP) -1 and -2. We hypothesized that variants in *GCG* associate with type 2 diabetes (T2D), obesity, and/or related metabolic traits.
Materials and methods: *GCG* was sequenced in 481 whites with adult or early-onset obesity or non-autoimmune diabetes and in 384 randomly chosen Danes. Twenty-nine different variants were identified and variants, which had minor allele frequency (MAF) ≥2% (rs4664447 and rs7581952) or were likely to be functional (Ile158Val and Trp169Ter) were genotyped in a total of 17,167 Danes (8,662 subjects from the ADDITTION study, 6,164 subjects from the INTER99 study along with 1,820 T2D patients and 521 glucose tolerant subjects.
Results: In a population-based study of treatment-naïve subjects we found that homozygous carriers of the rare A-allele of rs4664447, which is predicted to disrupt an essential splice enhancer binding site, had lower levels of fasting plasma glucose (mean±SD: 4.8±1.2 vs 5.5±0.8mmol/l, *P*=0.004), fasting insulin (22±14 vs 42±27 pmol/l, *P*=0.04) and glucose-stimulated serum insulin (159±83 vs 290±183 pmol/l, *P*=0.01), insulinogenic index (15±9 vs 29±19, *P*=0.04), and adult-height (165±10 vs 172±9cm, *P*=0.0009) compared to G-allele carriers. Following a hyperglycemic arginine stimulation test homozygous carriers of this variant had 40-50% decreased basal and stimulated levels of serum insulin, as well as plasma glucagon and fully processed GLP-2 compared to matched controls (*P* = <0.0001-0.0008). In studies of T2D patients and glucose tolerant individuals, the rare Val-allele of Ile158Val was associated with a higher prevalence of T2D, OR 1.83 (1.05-3.6), *P*=0.04. Finally, G-carriers compared with T-carriers of rs7581952, had lower BMI (26.4±5.8 vs 27.5±5.0 kg/m^2, *P*=0.009) and body weight (76±16 vs 82±17kg, *P*=0.004). Trp169Ter did not co-segregate with obesity or diabetes.

Conclusion: In the present biological candidate gene study in whites we demonstrate that *GCG* harbors rare variants, rs4664447, rs7581952 and Ile158Val with relatively higher impact on glucose metabolism, measures of obesity and T2D prevalence, respectively, than the impact of most common variants shown to influence metabolic traits identified through genome-wide association studies.

Influence of novel genetic loci affecting glucose and insulin levels during OGTT on islet function in man

T.S. Ahluwalia[1], C. Ladenvall[1], A. Jonsson[1], J. Kravic[1], E. Laurila[1], B. Isomaa[2], T. Tuomi[3], L. Groop[1], V. Lyssenko[1];
[1]Clinical Sciences: Diabetes and Endocrinology and Lund University Diabetes Centre, Malmö, Sweden, [2]Folkhalsan Research Centre, [3]Medicine, Helsinki University Central Hospital and Research Program of Molecular Medicine, Helsinki, Finland.

Background and aims: Type 2 diabetes (T2D) is characterized by chronically elevated glucose levels. Impaired insulin secretion and action are hallmarks of T2D. The Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC) identified 16 loci associated with fasting and postprandial glucose levels involved in glucose-sensing, signaling, insulin processing and cell proliferation. Only few of them, *ADCY5, DGKB, PROX1*, *GCK* and *GCKR* seem to influence risk of T2D. We investigated whether these genetic variants would also influence change in insulin secretion and/or action over time or proinsulin, glucagon, GIP, and adiponectin concentrations.
Materials and methods: In the Botnia prospective study (BPS), 2,444 non-diabetic subjects followed for a period of 8 years with OGTT and insulin measurements were genotyped for common variants in 16 loci (*PROX1*, *GCK*, *GCKR*, *G6PC2*, *ADCY5*, *SLC2A2*, *DGKB*, *GLIS3*, *ADRA2A*, *CRY2*, *MADD*, *FADS1*, *IGF1*, *VPS13C*, *C2CD4B* and *GIPR*). In the Botnia Prevalence Prevention and Prediction study (PPP) (N=5,200) in addition to glucose and insulin, fasting/postprandial glucagon and GIP levels, and adiponectin were measured.
Results: We could replicate previously observed associations of variants in *MTNR1B* (DI_{PPP}, beta=-0.237, $P=6\times10^{-29}$), *GIPR* (CIR_{PPP}, beta=-0.057, P=0.008), *FADS1* (CIR_{PPP}, beta=-0.060, P=0.002), *GCK* (DI_{PPP}, beta=-0.092, P=0.003) influencing decreased insulin secretion and *MTNR1B* (ISI_{PPP}, beta=-0.066, $P=2\times10^{-6}$) in decreased insulin sensitivity. In longitudinal BPS, we observed *CRY2* variant (CIR, beta= 0.008, $P_{interaction}=0.01$) associated with increased insulin secretion and *PROX1* (ISI, beta=-0.005, $P_{interaction}=0.03$) with decreased insulin sensitivity over time. The glucose raising allele of *MADD* variant was associated with increased fasting and 2hr (beta=0.166, $P=2\times10^{-8}$, beta=0.138, $P=3\times10^{-11}$), and *MTNR1B* with elevated 2hr (beta=0.062, P=0.0005) proinsulin levels, whereas *FADS1* with decreased (beta=-0.079, P=0.0006, beta=-0.051, P=0.002) fasting and 2 hr proinsulin levels. The 2hr glucagon levels were increased in *GLIS3* (beta=0.024, P=0.04), while decreased in *DUSP9* (beta=-0.049, P=0.01) variant carriers. Fasting GIP levels were elevated in carriers of *CRY2* (beta=0.078, P=0.03), and 2hr GIP in *PROX1* (beta=0.041, P=0.03). On contrary, fasting GIP was decreased in *GCK* (beta=-0.158, P=0.006), and (fasting and 2hr) in *GIPR* (beta=-0.087, P=0.03 and beta=-0.091, $P=2\times10^{-5}$) variant carriers. *MTNR1B* variant was associated with lower (beta=-0.073, P=0.0002) adiponectin concentrations.
Conclusion: These results demonstrate that genetic variants influencing glucose and/or insulin levels also show effects on other metabolic traits like, proinsulin (*MADD, FADS1*), glucagon (*GLIS3*, *DUSP9*), GIP (*GIPR*, *CRY2*, *GCK*), and adiponectin (*MTNR1B*). Low GIP levels in carriers of a loss-of-function variant in the *GIPR* gene in islets suggest the importance of non-receptor mediated mechanisms in determining GIP levels.

Extending criteria for genetic testing increases diagnosis of maturity-onset diabetes of the young

G. Thanabalasingham[1], A. Pal[1], A.J. Farmer[2], S. Ellard[3], M.I. McCarthy[1], K.R. Owen[1];
[1]OCDEM, University of Oxford, [2]Public Health, University of Oxford, [3]Molecular Genetics, Peninsula College of Medicine & Dentistry, Exeter, United Kingdom.

Background and aims: Increasing diagnosis rate of monogenic diabetes is essential to enable patients to benefit from optimal treatment and early diagnosis of family members. Current testing for Maturity Onset Diabetes of the Young (MODY) is largely restricted to individuals whose clinical features match the original descriptions of MODY families. This selection method has good specificity (94%) but low sensitivity (58%) in our dataset. Extended MODY testing criteria were defined to select subjects with atypical features of clinically diagnosed type 1 (T1DM) or type 2 (T2DM) diabetes (recruited from primary and secondary care), who then underwent re-sequencing of the Hepatocyte nuclear factor 1-alpha (*HNF1A*) and 4-alpha (*HNF4A*) genes.
Materials and methods: In those with apparent T1DM (n=247), *HNF1A/4A* re-sequencing was performed in individuals with residual β-cell function ≥3y from diagnosis defined as random or glucagon-stimulated c-peptide ≥0.2nmol/l (n=20). In those with apparent T2DM (n=291), *HNF1A/4A* re-sequencing was performed in those with diabetes diagnosed ≤30y (n=35) or diabetes diagnosed ≤45y with absence of metabolic syndrome (MS-, n= 53). Diagnosis rates were compared to those meeting standard diagnostic criteria for MODY; diabetes diagnosed ≤25y with parental diabetes (n=14).
Results: In the T1DM group, 2 *HNF1A* mutations were found. Both individuals had random c-peptide ≥0.2nmol/l and positive GAD antibody titres. In those with apparent T2DM, 10 *HNF1A* and 2 *HNF4A* mutations were identified. Mutations were found in 22% diagnosed ≤30y and 16% of MS-. Only 43% of the MODY cases found met current diagnostic testing guidelines. Family investigations have identified a further 11 mutation carriers including 2 with previously undiagnosed diabetes. Overall 24% of subjects have changed treatment following molecular testing.
Conclusion: We found a prevalence of transcription factor-MODY of 0.8% in apparent T1DM and 4.1% in apparent T2DM. Widened genetic testing criteria based on simple pathophysiological features more than doubled MODY diagnosis rates. Subjects with β-cell antibodies should not be excluded from testing.

The influence of carbohydrate content of diet on glycaemia in GCK-MODY patients

T. Klupa[1], I. Solecka[1], N. Nowak[1], M. Szopa[1], M. Borowiec[2], W. Młynarski[2], M.T. Malecki[1];
[1]Department of Metabolic Diseases, Jagiellonian University, Krakow, [2]Department of Pediatrics, Medical University of Lodz, Poland.

Background and aims: Heterozygous inactivating mutations in GCK gene encoding glucokinase result in maturity-onset diabetes of the young (MODY). Nutritional intervention remains the treatment of choice for this form of diabetes. An optimal diet formula for GCK-MODY patients remains, however, to be established. This clinical experiment was designed to evaluate the effect of diet carbohydrate (CH) quantity on glycaemia level in GCK-MODY patients.
Materials and methods: We exposed 8 GCK mutation carriers (6 with diabetes and 2 with impaired fasting glucose-IFG) to diet rich in CH (60% of daily calorie intake) for two days, then patients were switched to low CH diet (25% of daily calorie intake) for another two days. The caloric content was equal throughout the whole 4-day period. All patients were supposed to avoid high glycemic index products. Glucose levels were evaluated with continuous glucose monitoring (CGMS, MiniMed, USA).
Results: In 6 GCK-MODY patients glucose levels were significantly higher during exposure to diet rich in CH vs. low CH diet: the mean glycemia was 8.5 mmol/l (range 8.2-8.9 mmol/l) vs. 7.26 mmol/l (range 7.0-8.1 mmol/l), the mean time spent above the target level of 140 mg/dL was 41.4% (range 23%-55%) and 27.6% (range 13%-46%) ($p<0.02$ for both comparisons), respectively. In addition, 4 out of 5 patients experienced episodes of postprandial hyperglycemia above 200 mg/dL lasting for at least 15 min (on average 1.7 episodes/patient/day) when on high CH diet with no such episodes when on low CH diet. Interestingly, the carbohydrate content of meals had no major impact on glucose levels among GCK mutation carriers with IFG.
Conclusion: Postprandial hyperglycemia is observed on high CH diet in GCK-MODY patients. Diet with modestly limited carbohydrate intake may be effective in optimizing metabolic control in GCK-MODY. Carbohydrate restriction seems to have no major impact on glycemias in GCK mutation carriers not meeting formal criteria of diagnosis of diabetes.

OP 24 Childhood diabetes: What is new?

Is the distinction between immunologic type 1A and idiopathic type 1B-diabetes clinically relevant? A real-life study with 5 years of follow-up in 3302 paediatric patients with diabetes onset prior to age 12

R.W. Holl[1], S. Hofer[2], A. Thon[3], J. Rosenbauer[4], T. Kapellen[5], A. Icks[4], K. Warncke[6], B.O. Böhm[7], E. Schober[8], German-Austrian-DPV Initiative and German BMBF-Competence Network Diabetes;
[1]Epidemiology, University of Ulm, Germany, [2]Pediatrics, University of Innsbruck, Austria, [3]Pediatrics, Medical University Hannover, [4]Epidemiology, University of Düsseldorf, [5]Pediatrics, University of Leipzig, [6]Pediatrics, Technical University of Munich, [7]Internal Medicine, University of Ulm, Germany, [8]Pediatrics, University of Vienna, Austria.

Background and aims: The current diabetes classification distinguishes patients with immunologic type-1A and idipathic type-1B. However, few studies so far addressed the relevance of B-cell-autoimmunity at onset for the subsequent course of diabetes under real-life conditions.
Materials and methods: The DPV register was started in 1995 on a nationwide basis: In order to monitor and improve the quality of care, relevant data are documented prospectively at 327 specialized diabetes centers in Germany / Austria. By March 2010, 200722 patients are included in the database (63578 patients type-1). 16921 patients had a pediatric onset of type-1 diabetes prior to age 12, in 4254 of them at least two B-cell-antibodies (ICA, IA2, GAD or IAA at diagnosis) were measured. In 3302 patients, a continuous follow-up from diagnosis for 5 years was available (age at onset: 7.1±3.1 years, 50.4% male). Data were analyzed using non-parametrical comparisons for unadjusted and a hierarchical mixed linear model for adjusted comparisons. Mean daily insulin doses per kg and DCCT-equivalent HbA1c were adjusted for age at onset, gender, BMI and insulin regimen using observed marginal frequencies.
Results: No B-cell-antibody was present in 263 patients, 1 antibody only in 790 (AB1+) and 2 or more positive ABs were present in 2249 patients (AB2+). These groups did not differ by gender, age at onset, initial BMI, rate of DKA or HbA1c at onset, while the reported duration of symptoms was slightly longer in AB- (2.84 weeks) compared to AB1+ (2.39) or AB2+ (2.17 weeks, $p < 0.005$). Concomitant thyroid autoimmunity was present in 24.1 % of AB2+-patients compared to 17.6 % in AB1+ and 16.7 % in AB- patients ($p<0.001$, X^2-test). Based on adjusted means, daily insulin requirement was slightly, but significantly higher in double-antibody-positive compared to antibody-negative patients during the first 3 years of diabetes, but not thereafter (1st year: AB-: 0.52 U/kg versus AB2+ 0.55 U/kg, $p<0.05$). After 5 years of diabetes, insulin requirement was 0.83 U/kg in AB-, 0.85 U/kg in AB1+ and 0.85 U/kg in AB2+ patients (n.s.). Throughout the 5-year period, adjusted HbA1c-values did not differ between the 3 groups: 5th year of diabetes: AB-: 7.6 %, AB1+: 7.5 %, AB2+: 7.5 % (n.s.).
Conclusion: In this large cohort of prospectively followed children with type-1 diabetes, the presence of B-cell-autoimmunity at onset had only a small, clinically irrelevant and transient effect on daily insulin requirement, and no effect on metabolic control achieved. Based on antibody assays currently available in routine care, the presence of B-cell-AB at diagnosis is not predictive for disease severity after 5 years.

Early introduction of roots in infancy associated with advanced beta cell autoimmunity in young children with HLA-conferred susceptibility to type 1 diabetes

S.M. Virtanen[1,2], H.-M. Takkinen[2], J. Nevalainen[2,3], C. Kronberg-Kippilä[1], M. Salmenhaara[1,2], L. Uusitalo[1,2], M.G. Kenward[4], M. Erkkola[5], R. Veijola[6], O. Simell[7], J. Ilonen[8,9], M. Knip[10,11];
[1]Department of Lifestyle and Participation, National Institute for Health and Welfare, Helsinki, [2]Tampere School of Public Health, University of Tampere, [3]Department of Statistics, University of Turku, Finland, [4]Department of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, United Kingdom, [5]Department of Nutrition, University of Helsinki, [6]Department of Paediatrics, University of Oulu, [7]Department of Paediatrics, University of Turku, [8]Department of Virology, University of Turku, [9]Department of Virology, University of Eastern Finland, Kuopio, [10]Department of Paediatrics, Tampere University Hospital, [11]Hospital for Children and Adolescents, University of Helsinki, Finland.

Background and aims: Early introduction of supplementary foods has been implicated to play a role in the development of β-cell autoimmunity. We set out to study the effects of breastfeeding and age at introduction of supplementary foods on the development of β-cell autoimmunity.
Materials and methods: A prospective birth cohort of 6,069 infants with HLA-DQB1-conferred susceptibility to type 1 diabetes was recruited between 1996-2004. Antibodies against islet cells (ICA), insulin, glutamate dehydroxylase and islet antigen 2 were measured at 3 to 12- month intervals. The families recorded at home the age at introduction of new foods and completed for each visit a structured dietary questionnaire. The endpoint was repeated positivity for ICA plus at least one other antibody and/or clinical type 1 diabetes (n=265).
Results: Early introduction of roots (by the age of 4 months) was related to increased risk of developing positivity for the endpoint [hazard ratio (95% CI) for earliest third 1.75 (1.11-2.75) and for middle third 1.79 (1.22-2.62) compared to last third (>4 months), likelihood ratio test $p= 0.006$], independently of introduction of other foods and of several putative sociodemographic and perinatal confounding factors. Introducing wheat, rye, oats and/or barley cereals (p=0.013) and egg (p=0.031) early was related to an increased risk of the endpoint but only during the first 3 years of life.
Conclusion: Early introduction of roots during infancy is independently associated with increased risk of β-cell autoimmunity among Finnish children with increased genetic susceptibility to type 1 diabetes.

Effects of physical activity on insulin pump therapy in children and adolescents with type 1 diabetes: A randomised controlled trial

A.E. Gazzarri, M. Macedoni, S. Mazzantini, E. Giani, D. Spiri, A. De Palma, F. Redaelli, C. Mameli, L. Santoro, G. Zuccotti, A. Scaramuzza;
Paediatrics, University of Milano - Luigi Sacco Hospital, Italy.

Background and aims: Few papers have been evaluated the effects of physical activity on insulin pump therapy in children with type 1 diabetes. We evaluated the most effective strategy with insulin pump therapy in children with type 1 diabetes undergoing 2 hours of aerobic-anaerobic exercise.
Materials and methods: We enrolled 15 children and adolescents, aged 10-18 yrs (mean±SD 13.1±2.7 yrs), with type 1 diabetes for 7.2±3.3 yrs, (BMI of 20.05±3.05 m/kg2, insulin requirement 0.85±0.15 U/kg/day, HbA1c 7.66 ± 0.81 %), who were using an insulin pump. Exercise (2 h of anaerobic-alactacid, anaerobic-lactacid and aerobic training prepared and supervised by a qualified trainer) has been maintained at the same level during each session (reliability has been evaluated by means of an arm band), and replicated by each patient for four consecutive days, with a different insulin pump scheme randomly assigned. The four schemes were as follow: the first day the pump has been kept active during exercise; the second day the pump has been suspended during exercise; the third day the pump has been suspended after a 'correction' bolus (the amount of the insulin bolus was equal to the basal insulin the patient would have injected during the 2h-exercise, reduced by 30%); the fourth day was as the third day, plus a temporary basal scheme 20% reduced applied 2 h prior and 4 h after exercise.
Results: Keeping the pump active, glycemic profiles were excellent during exercise, but we observed a significant lowering of blood sugar readings 3 h

after exercise (4/15 patients had had mild hypoglycemia), with a subsequent glycemic increase during the night. The suspension of the pump has shown good glycemic profiles, even if with a significant increase 90 minutes after exercise. The 'correction' bolus determined a significant lowering of glycaemia after 90 minutes from the beginning of exercise. The use of temporary basal scheme showed the highest glycemic variability (table).
Conclusion: We conclude that keeping pump active during exercise seems the best option to properly manage exercise in children with type 1 diabetes, with the recommendation to reduce basal rate by 20% for the 2-4 h after exercise, in order to avoid late-onset hypoglycaemia. However, for those sports that do not allow the use insulin pump, suspending the pump might be a good option, if followed by a +20-30% temporary basal for 2-4 h after exercise.

Glycaemic values during and after exercise according to different insulin pump patterns

	During	During	During	During	After	After	After	Night	Night
	T 0 min	T 60 min	T 90 min	T 120 min	T 60 min	T 120 min	T 180 min	Midnight	3 o'clock
Insulin pump active	117±51	139±64	134±79	130±98	121±75	126±45	98±44	175±101	182±84

How common is common hypoglycaemia? Frequency of hypoglycaemia in insulin treated children <7years. A one year prospective study of self measured blood glucose
F. Sundberg, G. Forsander;
The Queen Silvia Childrens Hospital/ Sahlgrenska University Hospital, Gothenburg, Sweden.

Background and aims: Hypoglycemia is often regarded as the limiting factor when striving for good glycemic control. ISPAD has defined the HbA1c goal as <7, 5 % in children. Preschool children with insulin treated T1DM are prone to have fluctuating p-glucose and frequent hypoglycemias. The cognitive consequences of hyper- and hypoglycemia during early childhood are under debate. Acute hypoglycemia causes discomfort and interrupts playing and other important activities of the child. Fear of hypoglycemia might affect the parents. The aim of this study was to describe the frequency of hypoglycemia in children < 7 years of age with insulin treated T1DM and the number of nights with hypoglycemia during one year.
Materials and methods: Our hospital serves all patients with Diabetes Mellitus younger than 18 years living in the city of Gothenburg, Sweden and surrounding area. All 36 patients who met the inclusion criteria (age<7 years, T1DM with duration > 3 months, patient at our diabetes unit) were invited to participate in a one year prospective multidimensional study ("DU7"). As a part of this study all SMBG was collected prospectively from autumn 2008 until autumn 2009.The parents of 17 children gave informed consent to participate and 14 of them managed to upload >300 days of p-glucose values from their child's glucometer. Data was collected with the software Diasend. HbA1c was measured with DCA Vantage TM Analyzer, which was calibrated in accordance with Equalis standard, and the values were translated into DCCT standard. HbA1c was measured at the study start and at least four times during the year and the mean value of the year was used for every child. Night was defined as 22-06. Hypoglycemia was defined as p-glucose< 4mmol/l. Severe hypoglycemia was defined as seizures or unconsciousness. 14 children (8 boys) aged 4.8 (1.8-6.9) years with a diabetes duration of 2.4 (0.6-4.7) years participated. 11 were on CSII and 3 on MDI when the study started, one shifted to CSII during the year.
Results: The average mean HbA1c was 7.8 (7.1-8.7) %. 7/14 (50%) had mean HbA1c <7.5 %. The mean p-glucose testing frequency was 2849 (1157-5209) per patient year with mean 7.8 (3.2-14.2) values per day. The mean frequency of hypoglycemia detected by SMBG was 241 (150-385) per patient year. The mean number of nights with detected hypoglycemia was 21 (4-42) per patient year. The mean number of night time SMBG was 452 (73-906) values per patient year. One child reported two and one child reported one severe hypoglycemia (21 events per 100 patient years).
Conclusion: The mean frequency of hypoglycemia was 0.66 events per day (or 4.6 events per week). The children were hypoglycemic 6 (1-12) % of the nights. We need to identify age-specific strategies to improve insulin treatment for preschool children. Further data on how to balance nutrition, insulin and physical activity in order to achieve good glycemic control and thereby preserve health and quality of life in the short and long perspective are needed.

Suboptimal vitamin D status as a risk factor for CF-related diabetes in the Scandinavian Cystic Fibrosis Nutritional Study
T. Pincikova[1], K. Nilsson[1], I. Moen[2], G. Fluge[3], A. Hollsing[4], P. Knudsen[2], A. Lindblad[5], L. Mared[6], T. Pressler[7], L. Hjelte[1];
[1]Stockholm CF Center, B 59, Karolinska Institutet, Karolinska University Hospital Huddinge, Stockholm, Sweden, [2]National Center for Cystic Fibrosis, Oslo University Hospital Ullevaal, [3]Cystic Fibrosis Center, Department of Pediatrics, Haukeland University Hospital, Bergen, Norway, [4]Uppsala Cystic Fibrosis Center, KBH, Uppsala University Hospital, [5]The West Swedish CF Center, Sahlgrenska University Hospital, Gothenburg, [6]Heart and Lung Center, Lund University Hospital, Sweden, [7]Cystic Fibrosis Center, Department of Pediatrics, Copenhagen University Hospital, Denmark.

Background and aims: Cystic fibrosis (CF) is the most common life-shortening autosomal recessive disorder in Caucasians. The two main clinical characteristics of CF are progressive pulmonary disease and pancreatic insufficiency. CF-related diabetes (CFRD) is a major complication of CF. With better medical care and longevity, prevalence of CFRD in adult CF population is increasing and reaches up to 30%. CF patients worldwide are vitamin D insufficient. Recent literature suggests that vitamin D might possess certain antidiabetic properties. We aimed to assess the relationship between vitamin D and CFRD, glucose tolerance and HbA1C using cross-sectional data gathered in the Scandinavian CF Nutritional Study.
Materials and methods: 898 CF patients were included (0.25 - 65 years) from 7 centers in Denmark, Norway and Sweden. Serum 25-hydroxyvitamin D (25(OH)D) and HbA1C were measured, oral glucose tolerance test (OGTT) was carried out and vitamin D intake data were gathered using a seven-day dietary food record. Multiple linear regression analyses were performed for CFRD diagnosis, OGTT result and HbA1C as dependent variables, and serum 25(OH)D, vitamin D insufficiency degree, daily food and supplemented vitamin D sources of intake as independent variables. The model was controlled for country and centre, as well as for known CFRD risk factors: age, gender, genotype, liver dysfunction, long-term oral corticosteroid treatment, lung function and pancreatic insufficient vs. sufficient phenotype.
Results: In the group of all patients included in the study, CFRD diagnosis was positively associated with serum 25(OH)D < 30 nmol/L (N=718; adjusted R^2=10,7%; beta=0,06; p=0,031) and vitamin D insufficiency degree (beta=0,025; p=0,033), and negatively associated with supplemented vitamin D per kg bodyweight (beta=-0,035; p=0,045). HbA1C value was positively associated with 25(OH)D < 30 nmol/L (N=698; adjusted R^2=40,0%; beta=0,207;

p=0,009), 25(OH)D<50 nmol/L (beta= 0,147; p= 0,024) and vitamin D insufficiency degree (beta=0,081; p=0,016). In the subgroup of CF patients without CFRD diagnosis, 25(OH)D<30 nmol/L was a significant determinant of the HbA1C value (beta= 0,15; p=0,035). In non-diabetic CF patients younger than 18 years, 25(OH)D<30 nmol/L determined the HbA1C value even more strongly (beta= 0,24; p=0,006). In non-diabetic CF patients, 18 years old or older, 25(OH)D<30 nmol/L did not determine the HbA1C value. Instead, total vitamin D intake per kg bodyweight was negatively associated with HbA1C in this patient group (beta=-0,95; p=0,045).
Conclusion: Increasing vitamin D intake may have some antidiabetic effect. The study supports the proposed role of vitamin D insufficiency in the pathophysiology of diabetes mellitus and substantiates prospective studies.

Exenatide lowers postprandial glycaemia and increases satiety without side effects in Prader-Willi syndrome
A. Viardot[1], L. Sze[2], L. Purtell[3], G. Loughnan[4], E. Smith[5], H. Herzog[6], K. Steinbeck[4], L.V. Campbell[3];
[1]Investigative Medicine, Imperial College, London, United Kingdom, [2]Clinics for Endocrinology, Diabetes and Clinical Nutrition, University Hospital Zurich, Switzerland, [3]Diabetes & Obesity Research Program, Garvan Institute of Medical Research, Sydney, [4]Prader-Willi Syndrome Clinic, Metabolism & Obesity Services, Department of Endocrinology, Royal Prince Alfred Hospital, Sydney, [5]Department of Cytogenetics, The Children's Hospital, Westmead Clinical School, Westmead, [6]Neuroscience Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Background and aims: Prader-Willi syndrome (PWS) is associated with hyperphagia and obesity, the major burdens in management of this complex disease. Pharmacological interventions have been disappointing so far, and behavioural constraints are still the only effective option today. Exenatide has demonstrated to have beneficial effects on appetite suppression and weight loss, in addition to its glucose lowering effects, but it also has significant side effects. To our knowledge, exenatide has not been tested as a suitable intervention against hyperphagia and obesity in PWS. Therefore, we conducted a single dose pilot study to investigate the safety and effectiveness of exenatide on appetite regulation, glucose homeostasis and appetite hormones in PWS and obese control subjects.
Materials and methods: We recruited 8 subjects with PWS and 11 obese controls (OB) matched for age, sex and body fatness, assessed by DXA. Two standardised meal studies were performed, where subjects received either a single dose of 10 ug exenatide or normal saline injected sc 15 min before meal initiation in a single blinded cross-over design. Glucose, insulin, PYY, GLP-1 and ghrelin were measured for 4 hours postprandially. Appetite and satiety were assessed by visual analogue scale (VAS). Resting energy expenditure (REE) was assessed by indirect calorimetry.
Results: PWS and OB were well matched for central and total body fat mass. Fasting glucose, insulin and degree of insulin resistance (HOMA-IR) were similar in both groups. Exenatide was well tolerated in PWS with no side effects recorded, in contrast to marked side effects observed in OB (bloating 55%, nausea 45%, vomiting 18%). Exenatide significantly increased satiety 120 min after meal initiation (PWS, VAS 1.9±0.4 to 5.3±1.1, p<0.05; OB, VAS 3.5±0.7 to 5.4±0.8, p<0.05), but did not reduce appetite in both groups. Glucose and insulin levels were lowered similarly in both groups. Furthermore, GLP-1 and PYY levels were suppressed to a similar degree. However, ghrelin levels were not affected by exenatide in both groups. Fasting REE was not different between groups when corrected for lean body mass. However, the postprandial increase in REE was only observed in obese but not in PWS subjects (121±31 vs. 0±49 kcal/24h, p=0.048).
Conclusion: This is the first report on the use of exenatide in PWS, demonstrating that it is particularly well tolerated and also similarly effective in increasing satiety and lowering glucose as in simple obesity. Our observation of suppressed insulin and unchanged ghrelin levels challenges previous hypotheses on the cause of hyperghrelinemia in PWS, and it also suggests that delayed gastric emptying might be an important mode of action of exenatide. Longer and larger prospective studies should follow to investigate whether chronic administration of exenatide will lead to decreased food intake and weight loss in PWS.

OP 25 Diabetes morbidity and mortality

145

Significant excess mortality in middle-aged men with diabetes
C. Törn[1], S. Ingemansson[1], U. Lindblad[2], S. Gudbjörnsdottir[3], The DISS Study Group;
[1]Department of Clinical Sciences, Unit for diabetes and celiac disease, Malmö, [2]Department of Public Health and Community Medicine, University of Gothenburg, [3]The Nordic Research Academy for Global Health, The Nordic Research Academy for Global Health, Gothenburg, Sweden.

Background and aims: Several studies indicate that diabetes confers an increased risk for early death. The aim of this study was to explore all cause mortality, site of death and certainty of day of death in a national cohort of patients with diabetes followed for 15 years from diagnosis and compare with healthy controls.
Materials and methods: Patients aged 15-34 years at diagnosis were registered in the national register Diabetes Incidence Study in Sweden (DISS) during 1992 and 1993 (n=879). A healthy control matched for day of birth and sex was selected for each patient (n=837) at diagnosis of diabetes. Vital status of both patients (n=879) and controls (n=837) was ascertained through 2nd March 2009 by linking records to the Swedish Cause of Death Registry. The follow-up period represented a median of 15.9 years (range 1-17 years) and a total of 27173 person years.
Results: During 15 years of follow-up, 3.3% (29/879; 24 men and 5 women) of patients and 1.1% (9/837; 7 men and 2 women) of controls died. The risk for a patient with diabetes to die was almost three-fold increased HR=2.9; 95% CI 1.4-6.2. This risk was confined to men HR=2.8; 95% CI 1.2-6.5. Diabetes was the dominating cause of death among patients, identified as the underlying cause of death in 34% (10/29), and as a contributory cause of death in an additional five cases. The second most common cause of death in patients was circulatory diseases in 17% (5/29). Most patients 55% (16/29) died at home, remaining patients in hospital 28% (8/29) or elsewhere 17% (5/29) compared to controls of whom 33% (3/9; p=0.45) died at home, 33% (3/9; p=1.0) in hospital and 33% (3/9; p=36) elsewhere. Only 55% (16/29) of patients had a specified day of death on death certificates compared to 100% (9/9; p=0.016) of controls.
Conclusion: Adult men with diabetes had an almost three-fold increased risk to die within the first 15 years after onset of diabetes compared with healthy men. Most middle aged patients with diabetes died at home and often without a specified date of death recorded. The care of young and middle aged people with diabetes should consider the life situation.

Association of tight glycaemic control with nine-year mortality in type 2 diabetes patients
I. Strele[1], S. Rozite[2], G. Brigis[1], V. Pirags[3];
[1]Riga Stradins University, [2]Centre of Health Economics, [3]University of Latvia, Riga, Latvia.

Background and aims: Results of some clinical trials have recently suggested that intensive glycaemic control in type 2 diabetes patients, even if reducing the risk of cardiovascular events, does not show a benefit in terms of mortality. The aim of this analysis was to assess the pattern of the relationship between glycaemic control and mortality in type 2 diabetes patients, based on observational data.
Materials and methods: The study population consisted of 3665 type 2 diabetes patients (1060 men and 2605 women) participating in the Latvian diabetes survey in 2000. All deaths (n=1429) that occurred within a subsequent nine-year period and causes of death were identified through the Latvian Diabetes Register and the Causes of Death Data Base of Latvia. The Cox proportional hazard model was used to test associations between the baseline HbA_{1c}, broken down in quintiles (Q1-Q5), and mortality after adjusting for sex, age, diabetes duration, and, subsequently, for frequency of blood glucose testing and education.
Results: Lower HbA_{1c} was associated with a lower risk of death in patients without insulin therapy, e.g. the lowest HbA_{1c} quintile (HbA_{1c}<6.76%), compared to the highest (HbA_{1c}>10.14%), was associated with a 40% reduction

of both all-cause (HR 0.57 (95%CI 0.47-0.70)) and cardiovascular (HR 0.57 (95%CI 0.44-0.74)) mortality, adjusted for sex, age and duration of diabetes. However, among insulin treated patients the lowest risk of death was for the second HbA_{1c} quintile (HR for death from any cause was 0.58 (95%CI 0.42-0.81) and from cardiovascular disease - 0.59 (95%CI 0.38-0.90)), but not for the first quintile (corresponding HRs were 0.80 (95%CI 0.56-1.12) and 0.88 (95%CI 0.57-1.35)). Adding the frequency of blood glucose testing and education into the model, albeit both of them were inversely associated with mortality, did not affect the above mentioned relationship (Table). The observed associations did not change substantially after the deaths, which occurred within the first three years, were excluded from analysis: e.g., among insulin treated patients HR for death from any cause was 0.95 (95%CI 0.63-1.42) for the first quintile of HbA_{1c} and 0.55 (95%CI 0.36-0.83) for the second, but HR for death from cardiovascular disease was 0.99 (95%CI 0.59-1.66) for the first and 0.53 (95%CI 0.30-0.91) for the second quintile of HbA_{1c}, compared to the highest quintile.

Conclusion: In insulin treated type 2 diabetes patients moderate (HbA_{1c} between 6.76 and 7.73%), but not tight glycaemic control (HbA_{1c}<6.76%), was associated with better long-term survival. However, tight glycaemic control predicted better survival in patients not treated with insulin.

Diabetes and insulin duration and cancer incidence: a register linkage study in Denmark

B. Carstensen[1], D.R. Witte[1], S. Friis[2];
[1]Steno Diabetes Center, Gentofte, [2]Department of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark.

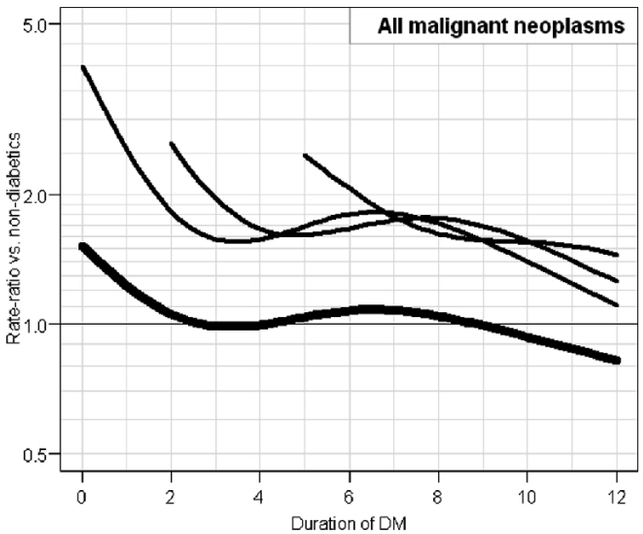
Background and aims: Studies of cancer occurrence among diabetes patients in the past decades have shown elevated rates of cancer of the liver, kidney, female breast and corpus uteri in studies based on up to 8800 cancer cases or 30,000 deaths. Our aim was to extend these studies to assess the effect of diabetes duration and duration of insulin treatment on cancer incidence in the entire Danish population.

Material and methods: We linked the Danish National Diabetes Register and the Danish Cancer Register and followed diabetes patients for the occurrence of cancer and compared with the cancer occurrence in the non-diabetic part of the population. For those diagnosed with diabetes after 1995 we have reliable data on DM duration and the time since first insulin use. For these patients we modelled the effect of DM duration and duration of insulin use on the cancer occurrence rates. We used Poisson models for data in 1-year intervals by age and date of follow-up, date of birth, and in 6-month intervals by duration of disease and insulin treatment.

Results: We had 1.9 mio. years of follow-up, and observed a total of 30,000 cancer cases among the diabetes patients. We found a rate-ratio (RR) of 1.15 for all cancers combined. RRs over 1 were seen for cancers of the digestive tract, with a tendency of decreasing RR from oesophagus to rectum. The RR for liver cancer was elevated (M: 3.7, F:1.8) as well as for pancreas cancers (M and F: 3.0). Other cancer types with a substantially elevated RR were corpus uteri, kidney and lymphomas. Significant but small RRs were seen for lung cancer and female breast cancer. Testis cancer had a RR of 0.8, non-significant. For all cancer types combined, we found the effect of insulin use was highest just after start of treatment, starting at an RR of 2 and decreasing to a stable level of 1.5 after 3 to 4 years after first insulin prescription (based on analyses restricted to DM diagnoses after 1995; 1.1 mio. PY, 18,000 cancers). This pattern was also seen for duration of diabetes, with the risk being highest in the period just after diagnosis at RR 1.5 decreasing to 1 (no excess risk) after 3 years.

Conclusion: Besides the well known elevated cancer risk among diabetes patients, we found that patients on insulin carry an extra risk of cancer, in the order of magnitude of 50% relative to the general population. The effect of diabetes duration and insulin is highest immediately after disease/treatment onset, indicating that it may not be duration or insulin per se that carries the risk, but partly causes common to cancer and diabetes/insulin treatment, such as obesity. This study is the largest of diabetes and cancer incidence so far, and the only one to model the duration effects of both diabetes and insulin treatment. We have however no detailed phenotypic information on the entire Danish population allowing us to control for obesity and other known risk factors for diabetes.

The thick line shows the RR for patients not on insulin, and the thin lines the RR for patients starting insulin 0, 2 and 5 years after disease onset.



148

Diabetes and pancreatitis: A population based study to determine the prevalence and incidence of pancreatitis in people with and without diabetes

H. Mani[1,2], B. Thakrar[3], M.J. Davies[1,2], K. Khunti[4];
[1]Diabetes and Endocrinology, University Hospitals of Leicester, [2]Cardiovascular Sciences, University of Leicester, United Kingdom, [3]Roche AG, Bern, Switzerland, [4]Health Sciences, University of Leicester, United Kingdom.

Background and aims: Acute Pancreatitis is one of the most common gastroenterological diseases. Incidence of acute pancreatitis has been increasing in the past 40 years. The most common causes of acute pancreatitis are gallstones and alcohol followed by idiopathic aetiology. There has been recent interest in concomitant increase of acute pancreatitis, type 2 diabetes (T2DM), and obesity with their associative risk factors for pancreatitis. The increasing use of incretin based therapies and their possible association with pancreatitis has also added to the debate. With limited published epidemiological data on pancreatitis in people with diabetes, we used the UK General Practice Research Database to investigate if there is an association between diabetes and pancreatitis.

Materials and methods: We identified all patients, ≥ 18 years, who were alive on 1st January 2004 and had at least one year previous history in the database. From these patients a cohort with a diagnosis of T2DM prior to index date was identified. The remaining patients formed the comparator cohort. From both cohorts those with a diagnosis of pancreatitis prior to index date were excluded. The two cohorts were followed forward from index date until the patients' last date to determine the incidence rate of pancreatitis. Relative risk of acute pancreatitis, comparing the two cohorts, was estimated after adjusting for gender and age using Poisson regression.

Results: Of 2.34 million patients aged 18 and over in the database, 75322 (3.2%) had a history of T2DM. Overall 574 people with diabetes (0.76%) had a previous history of pancreatitis (vs. 0.17% in those without diabetes). After

adjusting for age and gender, odds ratio for history of pancreatitis in people with diabetes compared to those without was 3.05 (95%CI: 2.79-3.35). In the incident cohort, we included 74748 people with diabetes and 2,263,766 controls with a mean age of 66 and 48 respectively. The mean follow up was 3.1 years for people with T2DM and 3.2 years for control group. There were 134 incident cases of acute pancreatitis in the people with diabetes and 1975 in the controls. The crude incident rate was 57.5 and 27.4 per 100,000 person years respectively, equal to a ratio of 2.09. After adjusting for age and gender, the relative risk of acute pancreatitis associated with diabetes was 1.47 (95%CI: 1.23-1.76). The relative incidence rate of pancreatitis in different age and sex groups are shown in table.

Conclusion: There is both an increased prevalence and incidence of pancreatitis in people with diabetes compared to those without diabetes. Incidence of pancreatitis in UK general population has increased compared to previous report of 10/100000 per year. The increasing incidence of T2DM might be a contributory factor in increasing incidence of pancreatitis.

Table. Relative risk of acute pancreatitis associated with gender, age, and diabetes

Gender	Age in Years	People with T2 Diabetes (N=74810)				People without Diabetes (N=2,825,782)				Relative Incidence rate Diabetes/No Diabetes

Risk prediction of cardiovascular disease in type 2 diabetes - a new risk equation from the Swedish NDR

B. Zethelius[1], S. Gudbjörnsdottir[2], B. Eliasson[2], K. Eeg-Olofsson[2], A.-M. Svensson[3], J. Cederholm[1];
[1]Uppsala University, [2]Gothenburgh University, [3]Center of Registers Västra Götaland, Gothenburgh, Sweden.

Background and aims: Risk prediction models obtained in samples from the general population do not perform well in type 2 diabetes (T2DM) patients, and 5-year risk estimates are proposed more accurate than 10-year risk estimates. We assessed the association of risk factors with cardiovascular disease (CVD), in order to elaborate a risk model for the absolute 5-year risk of CVD in patients with T2DM from the Swedish National Diabetes Register (NDR).

Materials and methods: Investigational sample consisted of 20,571 female and male patients aged 18-70 years, 14% with a history of CVD before baseline in 2002-03, with 1,776 fatal/nonfatal CVD events when followed for 5 years from 2003 to 2007. A separate sample of 2,898 female and male patients aged 18-70 years, was used for application of the risk model, 14% with previous CVD, with 223 CVD events when followed for 4 years from 2004 to 2007.

Results: Adjusted hazard ratios at Cox regression for fatal/nonfatal CVD for a 1 standard deviation increase in continuous variables were: 1.55 for T2DM onset age; 1.53 for T2DM duration; 1.19 for Total-/HDL-Cholesterol ratio; 1.13 for HbA1c; 1.12 for systolic BP; 1.07 for BMI; and dichotomous variables, 1.51 for male gender; 1.44 for smoking; 1.29 for microalbuminuria; 1.49 for macroalbuminuria (>200 µg/min); 1.67 for atrial fibrillation and 1.73 for previous CVD. All 12 variables were used to elaborate the risk equation for 5-year CVD risk. Calibration was excellent when assessed by comparing predicted 5-year risk, mean 10.34±7.1%, and observed 5-year failure rate at survival analysis, 9.94 (95% CI 9.48-10.43) %, with a ratio of 1.04. Figure 1 shows the association between predicted and observed survival rate for CVD. Discrimination was sufficient, with a receiver operator curve (ROC) statistic of 0.70 at logistic regression, and with sensitivity for predicted risk ≥5%; 95% and specificity for risk <10%; 63%. Application of the 4-year CVD risk estimated with use of the presented risk model in another 2,898 separate T2DM patients followed for 4 years still showed a good calibration when comparing predicted 4-year risk, mean 8.80±6.2%, and observed 4-year failure rate at survival analysis, 7.81 (95% CI 6.89-8.86) %, with a ratio of 1.13. Discrimination was sufficient, with a ROC-statistic of 0.73, and with sensitivity for predicted risk ≥5%; 96% and specificity for risk <10%; 72%.

Conclusion: This risk model for the 5-year CVD risk based on 12 predictors, elaborated in a large observational study from the normal population of T2DM, showed adequate calibration and discrimination, and should be useful for clinical practice. However, the risk model also needs to be tested in samples including patients with T2DM from other countries or regions.

A new risk model for cardiovascular disease in type 1 diabetes

K. Eeg-Olofsson[1], B. Zethelius[2], A.-M. Svensson[3], S. Gudbjörnsdottir[1], B. Eliasson[1], J. Cederholm[2];
[1]Institute of Medicine, Göteborg, Sweden, [2]Department of Public Health and Caring Sciences, Uppsala, Sweden, [3]Center of Registers in Region Västra Götaland, Göteborg, Sweden.

Background and aims: Risk prediction models are lacking in patients with type 1 diabetes. We assessed the association of risk factors with cardiovascu-

lar disease (CVD), in order to elaborate a risk model for the absolute 5-year risk of CVD in patients with type 1 diabetes from the Swedish national diabetes register (NDR).
Materials and methods: 4601 female and male patients aged 20-70 years, 5.4% with a history of CVD before baseline in 2002, with 206 fatal/non-fatal CVD events when followed for 5 years from 2003 to 2007. Another sample of 5501 patients aged 20-70 years used for application of the risk model, 5.5% with previous CVD, with 219 CVD events when followed for 4 years from 2004 to 2007.
Results: Adjusted hazard ratios at Cox regression for fatal/nonfatal CVD with 1 standard deviation increase in continuous variables were 3.42 for diabetes duration, 1.62 for onset age, 1.26 for HbA1c, 1.23 for the ratio total-cholesterol : HDL-cholesterol, 1.14 for BMI, and 1.08 for systolic BP, and with the dichotomous variables smoking 1.94, macroalbuminuria (>200 μg/min) 1.49, a history of CVD 2.53, adjusted also for sex. All nine variables were used to elaborate the risk equation for 5-year CVD risk. Calibration was excellent when assessed by comparing predicted 5-year risk, mean 4.4±7.4%, and observed 5-year failure rate at survival analysis, 4.5 (95% CI 3.9-5.1) %, with a ratio of 0.98. Discrimination was sufficient, with a receiver operator curve statistic of 0.87 at logistic regression, and with sensitivity and specificity for the highest quartile of predicted risk (≥5%), 80% and 78% respectively. The presented risk model was applied in a separate sample of 5501 patients followed for 4 years and still showed good calibration when comparing predicted 4-year risk, mean 3.6±6.2%, and observed 4-year failure rate at survival analysis, 4.0 (95% CI 3.5-4.6) %, with a ratio of 0.90. Discrimination was sufficient, with a receiver operator curve statistic of 0.83, and with sensitivity and specificity for the highest tertile of predicted risk 83% and 69%. Figure 1 shows the association between predicted and observed survival rate for CVD.
Conclusion: This risk model for the 5-year CVD risk based on nine predictors, elaborated in a large observational study from the normal adult population of type 1 diabetes, showed adequate calibration and discrimination, and should be useful for clinical practice. However, the risk model also needs to be tested in patients with type 1 diabetes from other countries.

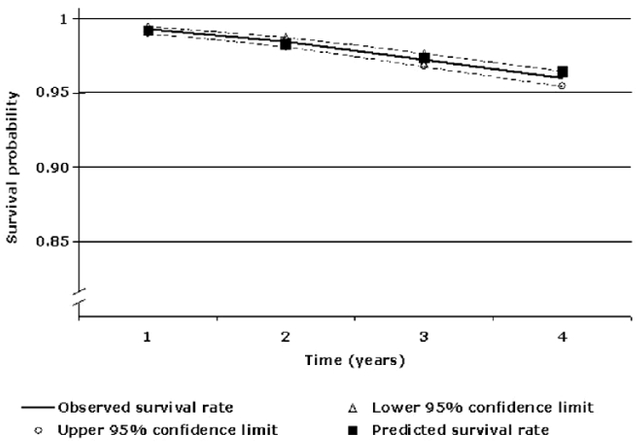

Figure 1. 5501 patients used for application of the risk model.

OP 26 Hypertension and retinopathy

151

Risk of hypertension in people with IGT: effect of postprandial glucose control

M. Hanefeld[1], C. Köhler[1], T. Westermeier[2], G. Saunders[3], J.-L. Chiasson[4]; [1]Center for Clinical Studies, GWT-TUD GmbH, Dresden, [2]Center for Clinical Studies, Bayer Vital GmbH, Leverkusen, Germany, [3]Enterprises Inc., Drayton Valley, [4]Center for Clinical Studies, Universite de Montral, Montreal, Canada.

Background and aims: Already prediabetes is associated with a high prevalence of hypertension. There exists now evidence from prospective clinical trials that people with impaired glucose tolerance (IGT) represent a high risk group for development of hypertension. So far, little is known on risk factors and impact of glucose control in the prediabetic stage on development of hypertension. This report analyses (1) risk factors for hypertension (2) effect of glucose control by acarbose on incidence of newly diagnosed hypertension in the data pool of the randomized placebo-controlled STOP-NIDDM trial.
Materials and methods: In this multinational trial 14, 742 subjects (age 40-70 years, BMI 25-40 kg/m², > 95 % Caucasians) were screened with a 75 g oGTT, 1,429 eligible patients with IGT were randomised, 1,368 were valid for ITT analysis, mean follow-up time 3.3 years.
Results: At baseline 666 (48.7%) (341 placebo, 325 acarbose) patients were normotensive and 702 (51.3%) had a hypertension (BP>=140/90 mmHg and/or antihypertensive drugs), 96 (14.4%) developed hypertension, annual progression rate of 4.4%. In the intervention group 10.5% developed hypertension vs. 18.2% in the placebo arm. Patients with subsequent development of hypertension had significantly higher levels of blood pressure at baseline. In univariate analysis of time to development of hypertension large waist circumference, metabolic syndrome and treatment group were the only significant predictors. Multivariate analysis confirmed only treatment group as significant variable with a hazard ratio in favour of acarbose of 0.59 (C.I 0.35-0.90).
Conclusion: In about any second subject IGT was associated with hypertension before glucose lowering treatment. At follow-up IGT was accompanied by a high incidence of hypertension (annual rate 4.4%). Control of postprandial hyperglycemia by acarbose reduced significantly rate of newly diagnosed hypertension.

152

Cardiorespiratory fitness and reduction in blood pressure and insulin resistance during lifestyle intervention

N. Stefan[1], C. Totsikas[1], J. Röhm[1], K. Kantartzis[1], C. Thamer[1], K. Rittig[1], J. Machann[2], F. Schick[2], J. Hansel[1], A. Niess[1], A. Fritsche[1], H.-U. Häring[1]; [1]Department of Internal Medicine, [2]Section of Experimental Radiology, University of Tübingen, Germany.

Background and aims: Lifestyle intervention, in general, is effective for improving arterial hypertension and other cardiovascular risk factors. However, there is a large variability in these responses. Because high cardiorespiratory fitness (CRF) protects from cardiovascular disease and mortality, we determined whether CRF at baseline predicts the improvement of blood pressure, insulin resistance and other cardiovascular risk factors during a lifestyle intervention.
Materials and methods: A total of 219 subjects at risk for type 2 diabetes, who underwent a 9 months lifestyle intervention with diet modification and increase in physical activity, and had measurement of CRF, were studied. Insulin sensitivity was estimated during a 75g oral glucose tolerance test. Total body-, visceral- and liver fat were measured by magnetic resonance (MR) tomography and ^{1}H-MR spectroscopy. CRF was estimated during incremental cycle exercise (maximal aerobic capacity-VO_{2max}) and motorized treadmill (individual anaerobic threshold-IAT) tests.
Results: During the intervention adiposity, glycemia, CRF and insulin sensitivity largely improved (all $p<0.0003$), however, blood pressure and serum lipids only moderately decreased (all $p<0.06$). High CRF at baseline predicted a larger decrease in systolic ($p<0.0002$) and diastolic ($p<0.004$) blood pressure, and a larger increase in insulin sensitivity ($p<0.04$), but not change in serum lipids (all $p>0.06$).While weight loss was similar among quartiles of CRF ($p>0.17$), systolic ($p<0.0009$) and diastolic ($p<0.01$) blood pressure only decreased in the higher two quartiles. For 1 SD increase in CRF at baseline

the odds ratio for resolution of hypertension or prehypertension was 2.26 (95% CI, 1.40-3.80) for IAT and 1.75 (95% CI, 1.08-2.89) for VO_{2max}.
Conclusion: We provide novel data that measurement of CRF at baseline helps to predict the effectiveness of a lifestyle intervention in improving blood pressure and insulin sensitivity in humans.

Static and dynamic retinal vessel analysis in normo- and hypertensive type 1 diabetic patients
A. Mandecka[1], W. Vilser[2], J. Dawczynski[3], M. Schwefer[4], M. Blum[5], N. Müller[1], C. Kloos[1], G. Wolf[1], U.A. Müller[1];
[1]Internal Medicine III, Friedrich Schiller University, Jena, [2]IMEDOS Systems UG, Jena, [3]Department of Ophthalmology, Friedrich Schiller University, Jena, [4]Department of Cardiology, Helios Clinic, Erfurt, [5]Department of Ophthalmology, Helios Clinic, Erfurt, Germany.

Background and aims: There is evidence that retinal vessel dilation results in disturbed autoregulation of retinal microcirculation in diabetic retinopathy (DR). On the other hand, stimulation of the retina with flicker light increases retinal vessel diameters in humans. The reduction of flicker light-induced vasodilation is considered endothelial dysfunction. We investigated the static calibre of retinal vessels and retinal vasodilation after stimulation with flickering light in type 1 diabetic patients with and without hypertension.
Materials and methods: Participants consisted of 76 control participants, 58 normotensive type 1 diabetic patients and 57 hypertensive type 1 diabetic patients. DR was classified according to the Early Treatment Diabetic Retinopathy Study criteria (no DR, mild- moderate and severe nonproliferative NPDR). The arteriolar retinal calibre (CRAE, µm) and flicker light-induced retinal vasodilatation (percentage increase over baseline diameter) was measured using Dynamic Vessel Analyzer.
Results: In normotensive diabetic patients, after adjustment for age, sex and glycated hemoglobin, patients without retinopathy (209.7 µm) and with mild NPDR (217.6 µm) had significantly wider arteriolar caliber compared to controls (183.2 µm). Patients with severe NPDR (190.9 µm) had significantly reduced CRAE in comparison to patients without DR or with mild NPDR. After adjustment for age, sex, glycated hemoglobin and CRAE the flicker-induced arteriolar dilation decreased with increasing stages of retinopathy (p-trend <0.014). In diabetic patients with hypertension, after adjustment for age, sex and glycated hemoglobin, patients without retinopathy (202.4 µm) and with mild NPDR (198.6 µm) had significantly wider arteriolar caliber compared to controls. Patients with severe NPDR (181.0 µm) had significantly reduced CRAE in comparison to patients without DR. After adjustment for age, sex, glycated hemoglobin and CRAE the flicker-induced arteriolar dilation decreased with increasing stages of retinopathy (p-trend <0.001). Normotensive patients with mild NPDR had, after adjustment for age, sex, glycated hemoglobin and diabetes duration, wider arteriolar caliber in comparison to hypertensive diabetic patients (p<0.007). Normotensive diabetic patients without retinopathy had wider arteriolar caliber compared to hypertensive patients (p<0.058).
Conclusion: In normotensive type 1 diabetic patients the initial stages of retinopathy are associated with wider arteriolar caliber in comparison to hypertensive patients. The arteriolar vasodilation results in disturbed autoregulation of retinal vessels. The distinct arteriolar vasodilation in normotensive type 1 diabetic patients may contribute to increased vulnerability of retinal microcirculation. Additionally, the flicker-induced arterial vasodilatation decreased significantly with increasing stages of retinopathy independent of CRAE. The decreased flicker-induced dilation of retinal vessels of diabetic patients implies the reduced capacity to autoregulate the blood flow in diabetic retinopathy.

154

The role of the vascular endothelial growth factor A in the progression of diabetic retinopathy
A.G. Kuzmin, D.V. Lipatov, T.A. Tchystyakov, O.M. Smirnova, M.I. Arbuzova, A.V. Ilyin, M.V. Shestakova;
Endocrinology Research Centre, Moscow, Russian Federation.

Background and aims: The diabetic retinopathy (DR) remains the main cause leading to the blindness among young people. There are many pathological mechanisms of DR progression. Vascular endothelial growth factor A (VEGF-A) is known to be a factor of the neovascularisation of the retina and development of the neovascular glaucoma (NG). The aim of this study was to investigate the level of VEGF-A in the aqueous humor (AH) in diabetic patients undergone to the cataract and glaucoma surgery, to estimate the grade of DR after the cataract operation and to analyze any correlations between the level of VEGF and DR stage.
Materials and methods: The study included 164 diabetic eyes (110 patients, among them 93 had type 2 diabetes mellitus (DM) and 17 - type 1 DM) and 24 nondiabetic eyes (20 patients) as a control group (CG). Glaucoma group consisted of 15 diabetic patients. All patients were operated due to the cataract or glaucoma; the phacoemulsification of the cataract, extracapsular cataract extraction or Ahmed glaucoma valve implantation were carried out. For assessment of VEGF-A the samples of AH were obtained during operation, were prepared by prompt centrifugation (15,000 g*min) and stored at -80°C. The VEGF-A value was analyzed by ELISA. The patient's examination included standard ophthalmological end endocrinological tests before and after operation. The grade of DR was measured using recommendation of WHO (1999). The grading of DR in diabetic patients was performed in 2 week after operation. The follow up period was from 1 till 24 month. Results of data were expressed as Mediana (95% CI). Relationship between the parameters was analyzed using nonparametric criteria.
Results: The VEGF-A value in patients without diabetes (CG) was 78,85 pg/ml (95% CI, 55,72-120,51). Among diabetic patients the DR grade estimated after cataract operation was the following: 10% eyes didn't have sings of DR, 33% had nonproliferative DR, 39% had preproliferative DR and 18% had proliferative DR. The VEGF-A value in diabetic patients without DR sings was 18,3 pg/ml (95% CI, 10,05-57,65), in patients with nonproliferative DR was 51,12 pg/ml (95% CI, 41,6-88,21), in patients with preproliferative DR was 74,5 pg/ml (95% CI, 66,61-113,03), in patients with proliferative DR was 337,56 pg/ml (95% CI, 234,58-422,79), (p<0,05) (fig.1). The patients with the NG had the VEGF-A value of 1634,01 pg/ml (95% CI, 610,69-2657,33), that was 20 times more than in CG.
Conclusion: Our data confirm the possible role of VEGF-A in the progression of neovascularisation of the retina and development of the NG.

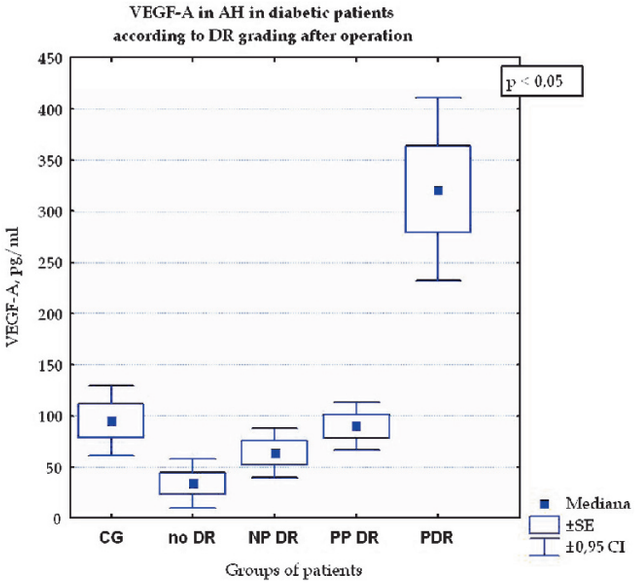

Figure 1: **CG** - control group; **no DR** - diabetic patients without DR; **NP DR** - patients with nonproliferative DR; **PP DR** - patients with preproliferative DR; **PDR** - patients with proliferative DR.

Immunologic markers at the clinical onset of type 1 diabetes mellitus and the risk of retinopathy 15 years later

R.A. Jensen[1], E. Agardh[2], Å. Lernmark[3,4], N.L. Smith[5,6], D.S. Siscovick[7], C. Törn[4];
[1]General Internal Medicine, University of Washington, Seattle, USA, [2]Department of Clinical Sciences, Ophthalmology, University Hospital MAS, Malmö, Sweden, [3]Department of Medicine, University of Washington, Seattle, USA, [4]Department of Clinical Sciences, Clinical Research Center, Lund University, Malmö, Sweden, [5]Department of Epidemiology, University of Washington, Seattle, [6]Seattle Epidemiologic Research and Information Center, Department of Veterans Affairs, Seattle, [7]Departments of Medicine and Epidemiology, University of Washington, Seattle, USA.

Background and aims: Previous studies have examined the associations of human leukocyte antigen (HLA) genes, islet autoantibodies and residual C-peptide with diabetic retinopathy (DR). In this study we examine the association of these factors, measured at the time of the clinical onset of type 1 diabetes mellitus (T1DM), with DR 15 years later using models to assess the independent effects each of these factors.
Materials and methods: The cohort was first identified in 1992 and 1993 by the Diabetes Incidence Study in Sweden (DISS) which attempts to enroll all incident cases of diabetes for patients between 15 and 34 years of age. Blood samples at diagnosis were analyzed for HLA genotype, islet autoantibodies and serum C-peptide. In 2008, copies of the most recent fundus photographs were obtained from existing patient records. Poisson regression was used to model the relative risk (RR) and 95% confidence interval (95% CI) of DR.
Results: Subjects with HLA DQ6 had a 70% reduced risk of any retinopathy 15 years after the clinical onset of diabetes compared to subjects without any DQ6, DQ8 or DQ2 haplotypes, RR = 0.29, (95% CI: 0.10 - 0.89). In addition, each unit increase in autoantibodies against the 65kD isoform of glutamate decarboxylase (GAD65, GADA) increased the risk of moderate or more severe DR by 45%, compared to subjects with mild or no DR, RR = 1.45 (95% CI: 1.01 - 2.07). C-peptide was not associated with DR.
Conclusion: We have shown that two immunologic factors capable of being determined at the clinical onset of T1DM may be useful to determine the risk of DR 15 years later. Not only does HLA DQ6 provide protection from developing T1DM it may also protect subjects from developing DR. In addition, increased levels of GADA at the time of diabetes onset were associated with the presence of moderate or more severe levels of DR.

Pericyte-endothelial cell interactions in co-culture models mimicking the physiological and diabetic retinal microenvironment, protective role of thiamine and benfotiamine

S. Tarallo, E. Beltramo, E. Berrone, M. Porta;
Dept Internal Medicine, University of Turin, Italy.

Background and aims: Pericytes regulate vascular tone and perfusion pressure in capillaries, and endothelial cell (EC) proliferation. Their selective loss in the early phases of diabetic retinopathy may cause angiogenesis, due to the failure of their control on endothelium proliferation. We standardized two human retinal pericyte (HRP)/EC co-culture models, to mimick the physiological and diabetic retinal microenvironment. Our aim in this work was to evaluate the interactions between co-cultured HRP/EC in terms of proliferation and apoptosis and the possible protective role of thiamine (T) and its lipophilic analogue benfotiamine (BT) against high glucose-induced damage.
Materials and methods: EC and HRP were co-cultured for 8 days in physiological glucose (NG, 5.6 mmol/l), stable high glucose (HG, 28 mmol/l) and intermittent HG (HGint, 48h HG/48h NG twice), with or without 50 µmol/l T or BT. *No-contact model*: EC were plated on the inner surface of a membrane suspended into the medium and HRP on the bottom of the same well, without physical cell-to-cell contact. *Cell-to-cell contact model*: EC and HRP were plated on the opposite sides of the same membrane, HRP being able to directly contact the abluminal surface of the EC through the pores of the membrane. In control experiments HRP and EC were plated on the relevant surfaces alone. Proliferation (cell counts and DNA synthesis, ELISA) and apoptosis (DNA fragmentation, ELISA) were measured.
Results: In the no-contact model, HG reduced proliferation of co-cultured EC (counts: -23.6%, DNA:-18.7%, $p<0.005$ vs NG), co-cultured HRP (counts: -24.6%, DNA: -12.9%, $p=0.001$ vs NG) and EC alone (counts: -22.5%, DNA: -20.3%, $p<0.05$) and increased apoptosis in co-cultured EC (+21.5%, $p<0.05$ vs NG) and HRP (+45%, $p<0.05$). In the contact model, both HG and HGint reduced co-cultured EC and HRP number (EC: -24.2 and -18.8%, respectively, $p<0.05$; HRP: -29.6 and -38.7%, $p=0.005$) and DNA synthesis (EC:-28.2 and -26.0%, respectively, $p<0.05$; HRP: -25.7 and -26.2%, $p<0.05$), while increasing co-cultured HRP apoptosis (HRP: +75.7 and +150%, $p<0.005$). Stable HG had no effects on HRP in separate cultures. Both EC and HRP proliferated more in co-culture than when cultured alone ($p<0.05$). T and BT countered HG and HGint induced-damage in all cases.
Conclusion: Retinal pericytes may be sensitive to soluble factors, whose nature remains to be clarified, released by the endothelium, cultured in high glucose conditions. Thiamine and benfotiamine are able to counteract this damage, confirming once again their possible role in the prevention/treatment of diabetic microvascular complications.

Incretins directly suppress the development of macrophage-driven atherosclerosis in apolipoprotein E-null mice

T. Hirano[1], M. Nagashima[1], T. Watanabe[2], K. Nohtomi[1], M. Terasaki[1], A. Miyazaki[2];
[1]Diabetes, Metabolism, and Endocrinology, [2]Biochemistry, Showa University School of Medicine, Tokyo, Japan.

Background and aims: Several lines of evidence suggest that the incretin-based therapies suppress the development of cardiovascular disease in type 2 diabetes. We investigated the possibility that glucagon-like peptide (GLP)-1 and glucose-dependent insulinotropic polypeptide (GIP) can prevent the development of atherosclerosis in apolipoprotein E-null (ApoE$^{-/-}$) mice.
Materials and methods: GLP-1 (1.5 pmol/kg/min) or GIP (17 pmol/kg/min) was continuously infused for 4 weeks into 17-week-old ApoE$^{-/-}$mice fed on atherogenic diet. Alternatively, DPP-4 inhibitor (PKF275-055, Vildagliptin analogue, Novartis) was administrated as drinking water for 4 weeks. Aortic atherosclerosis, oxidized LDL-induced cholesterol ester accumulation (foam cell formation), and its related gene expression in exudate peritoneal macrophages were determined.
Results: Administration of GLP-1, GIP, or DPP-4 inhibitor did not affect food intake, body weight, blood pressure, and plasma levels of lipids, glucose and insulin. Remarkable atherosclerotic lesions in the aorta were observed in 21-week-old ApoE$^{-/-}$ mice. Administration of GLP-1, GIP, or DPP-4 inhibitor significantly reduced the surface areas of atherosclerotic lesions and suppressed atheromatous plaque size and macrophage accumulation in the aortic root as compared with vehicle controls. The suppressive effects of incretins and DPP-4 inhibitor on atherosclerosis were associated with significant decreases in foam cell formation and down-regulation of acyl-CoA:cholesterol acyltransferase 1 (ACAT1) and CD36 in exudate peritoneal macrophages. Incubation with active GLP-1 or GIP but not inactive forms for 48 h resulted in significant suppression of foam cell formation in peritoneal macrophages obtained from non-treated ApoE$^{-/-}$ mice. The suppression of foam cell formation by incretins was totally cancelled by the pretreatment with the receptor antagonists, exendin9-39 or (Pro3)GIP. Both GLP-1 and GIP receptors were detected in the peritoneal macrophages of ApoE$^{-/-}$ mice.
Conclusion: Our study provided the first evidence that both GLP-1 and GIP directly and vildagliptin analogue seen at physiological levels of incretins by DPP-4 inhibition suppress the development of macrophage-driven atherosclerotic lesions associated with down-regulation of essential molecules of foam cell formation such as ACAT-1 and CD36.

Liraglutide inhibits endothelial cell dysfunction and expression of vascular adhesion molecules in an ApoE mouse model of atherogenesis

A.E. Dear[1], H. Liu[1], T. Gaspari[2], I. Welungoda[2], R.E. Widdop[2], L.B. Knudsen[3], R.W. Simpson[4];
[1]Medicine, Monash University, Melbourne, [2]Pharmacology, Monash University, Melbourne, Australia, [3]Research and Development, Novo Nordisk A/S, Bagsvaerd, Denmark, [4]Endocrinology, Box Hill Hospital, Melbourne, Australia.

Background and aims: Glucagon-like peptide-1 (GLP-1) is a hormone known to potentiate insulin and lower glucagon secretion. Recently, the once daily GLP-1 analogue, liraglutide, has been approved as a new treatment for type 2 diabetes. Most importantly liraglutide improves glycaemic control and lowers body weight. We have previously shown that liraglutide attenuates TNFα and mild hyperglycemia (10mmol/l)-mediated induction of plasminogen activator inhibitor-1 (PAI-1) and vascular cell adhesion molecule expression in human vascular endothelial cells (hVEC's). Endothelial cell dysfunction (ECD), an early abnormality in atherosclerosis and pre-diabetes, is associated with increased expression of vascular adhesion molecules. The aim of the current study was to determine whether liraglutide was vaso-protective in the non-diabetic ApoE$^{-/-}$ mouse model of ECD and atherosclerosis and establish the dependence of this effect on the GLP-1 receptor (GLP-1R).
Materials and methods: *In vitro studies*: ICAM-1 and VCAM-1 protein levels were determined in conditioned medium from C11-STH hVEC's treated with TNFα (10ng/ml) alone or TNFα + liraglutide (100nM) or TNFα + liraglutide +exendin (9-39)(100nM) for 16hrs using ELISA kits. Semi-quantitative RT-PCR was used to determine mRNA expression of ICAM-1 and VCAM-1. *In vivo studies*: ApoE$^{-/-}$ mice were fed a high fat diet for 16 weeks. Chronic liraglutide treatment was administered in the final 4 weeks via subcutaneous twice daily injection (total of 300μg/kg/day). Treatments included: saline (vehicle; s.c. injection twice daily), liraglutide (s.c. injection of 150μg/kg, twice daily), liraglutide + exendin (9-39) a GLP-1R antagonist (150pmol/kg/min via osmotic mini-pump). Post-treatment the abdominal aorta was divided into four aortic rings per mouse (~3mm long). Concentration response curves to the endothelium-dependent vasodilator acetylcholine (ACh) were constructed in preconstricted aortic rings.
Results: *In vitro* TNFα induced ICAM-1 and VCAM-1 mRNA and protein expression in C11-STH hVEC's at 16 hrs. This effect was significantly inhibited by the addition of liraglutide. The inhibitory effect of liraglutide on TNFα induction of ICAM-1 and VCAM-1 was attenuated by concomitant addition of exendin (9-39). Following these experiments *ex vivo* organ bath studies using isolated aortic rings taken from ApoE$^{-/-}$ mice on a high fat diet treated with liraglutide for 4 weeks demonstrated a significant improvement in endothelial function with liraglutide compared with vehicle treated mice (max relaxation: liraglutide R_{max} = 78.45±2.5% vs 55.36±6.89%; P<0.01; 2-way ANOVA). The improvement in endothelial function was completely abolished in mice co-treated with exendin (9-39) (R_{max} = 53.95±6.54%).
Conclusion: These observations suggest liraglutide significantly inhibits TNFα induction of ICAM-1 and VCAM-1 protein and mRNA expression *in vitro* in a GLP-1R dependent manner. *In vivo* liraglutide treatment significantly inhibited ECD also in a GLP-1R dependent manner. Based on these observations liraglutide may have the potential to attenuate atherogenesis.

Liraglutide regulates key hypothalamic appetite-related signals in diet-induced obese rats

N. Vrang[1], J. Jelsing[1], K. Raun[2], L. Bjerre Knudsen[2];
[1]Gubra, Frederiksberg C, [2]Novo Nordisk, Maløv, Denmark.

Background and aims: Glucagon-Like Peptide-1 (GLP-1) analogues are emerging as an important drug class for the treatment of diabetes and possibly also obesity. While the physiological basis of the anti-diabetic properties of GLP-1 analogues is well understood, less is known about the mechanisms underlying the weight loss effect.
Materials and methods: In the current study we examined the effects of 28 days of daily administration with the GLP-1 analogue liraglutide (0.2 mg/kg) on food intake, body-weight and energy expenditure in male diet-induced obese (DIO) rats compared to vehicle and food-restricted rats (weight-matched to the liraglutide group). Liraglutide reduced food intake (vehicle 530±12 g, liraglutide 439±6.7 g; p<0.0001 vehicle vs liraglutide) and body-weight (vehicle 685±6.0 g, liraglutide 626±5.6 g, p<0.001 vehicle vs liraglutide).
Results: Interestingly, weight-matched animals consumed less food than the liraglutide group (weight-matched 321±0 g; p<0.0001 liraglutide vs weight-matched). In line with these observations, 12-hour energy expenditure measurements at day 14 revealed a near significant increase in oxygen consumption in liraglutide-treated rats (ml/h/kg; vehicle 2051±112, liraglutide 2535±242, weight-matched 2037±200; p=0.12 vehicle vs liraglutide, p=0.089 liraglutide vs weight-matched). Semi-quantitative in situ hybridisations (ISH) on hypothalamic brain sections from liraglutide-treated rats revealed a marked and significant increase in mean cocaine and amphetamine-regulated-transcript (CART) mRNA levels in the arcuate (vehicle 100±15%; liraglutide 161±15%; weight-matched 109±11%; p<0.001 vehicle vs liraglutide) and paraventricular nuclei (vehicle 100±11%, liraglutide 190±30%, weight-matched 116±15%; p<0.01 vehicle vs liraglutide). Arcuate POMC mRNA levels were unchanged (vehicle 100±8.9%, liraglutide 91±0.11%, weight-matched 97±10%), whereas mean NPY (vehicle 100±10%; liraglutide 104±14%, weight-matched 141±10%; p=0.039 vehicle vs weight-matched) and AgRP (vehicle 100±10%, liraglutide 92±14%, weight-matched 174±17%; p<0.001 vehicle vs weight-matched) mRNA levels were significantly elevated in food-restricted rats only.
Conclusion: Our data demonstrate that the GLP-1 analogue liraglutide potently lowers food intake and body-weight possibly by: (1) an increase in arcuate CART mRNA; and (2) by blocking weight-loss-induced increases in arcuate NPY and AgRP mRNA levels.

Role of lysophosphatidylcholine in GIP secretion by primary K-cells

E. Diakogiannaki, F.M. Gribble, F. Reimann;
Clinical Biochemistry, University of Cambridge, United Kingdom.

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP) is a hormone secreted by enteroendocrine K-cells found in highest density in duodenal and jejunal epithelium. Apart from being a critical regulator of insulin secretion, GIP modulates pancreatic beta-cell proliferation and survival, and controls dietary fat metabolism. GIP has also been postulated to link over nutrition to the development of obesity as pharmacological and genetic interference with GIP signaling proved protective in several rodent obesity models. Although it is known to be secreted in response to the presence of nutrients in the gut lumen, and particularly ingested lipids, the molecular mechanisms involved in the nutrient sensing by K-cells and subsequent secretion of GIP are still unclear. Therefore, understanding these pathways is necessary for the elucidation of the role of the hormone in the development of obesity and type 2 diabetes. The aim of this study was to investigate the effects of lipid micelles on GIP secretion by K-cells.
Materials and methods: GIP secretion was assayed in primary duodenal cultures and STC-1 cells. Ratiometric [Ca2+]i imaging experiments and FRET based [cAMP]i and were performed on STC-1 cells.
Results: Experiments were performed on primary cultures of murine duodenal epithelium and the enteroendocrine model cell line STC-1. To simulate the conditions epithelial cells experience after a lipid rich meal, "postprandial micelles", comprised of oleic acid (200μM), 2-monooleoyl glycerol (70μM), L-α-lysophosphatidylcholine (LPC) (70μM), cholesterol (17μM) and taurocholic acid (TC) (700μM), were applied. Both primary and STC-1 cells responded to lipid micelles by secreting enhanced amounts of GIP (9.2 fold and 3.1 fold stimulation, respectively compared to baseline, $p<0.001$ for both). The stimulation of GIP secretion by lipid micelles was not attributable to cell lysis, as monitored by lactate dehydrogenase activity released into the supernatant. Fluorescence calcium imaging measurements in STC-1 cells, following loading with Fura-2AM, demonstrated elevations in intracellular calcium in response to lipid micelles ($R_{340/380}$ increased 1.8 fold compared to baseline $p<0.001$ n=104). To investigate the relative importance of the different micellar lipids for the secretory response a series of experiments was performed omitting individual components. Exclusion of LPC significantly reduced secretory responses in both primary and STC-1 cells (46% in primary cells n=7 $p<0.05$; 22% in STC-1 n=12, compared to stimulation by micelles containing LPC). Replacement of LPC with phosphatidylcholine (PC) could not compensate (1.14-fold stimulation by micelles containing PC in primary cells; n=4). LPC (in the presence of 700μM TC) promoted the release of GIP in a dose dependent manner over the range of concentrations between 1-100μM. Both in the presence and absence of TC, 70 μM LPC stimulated reversible rises in the cytosolic Ca^{2+} and cAMP concentration monitored in STC-1 cells preloaded with Fura2 or transfected with a Epac2-based FRET-sensor respectively.
Conclusion: Lipid micelles stimulate GIP secretion from primary murine cultures and STC-1 cells. One of the components, LPC, enhanced intracellular concentrations of calcium and augmented levels of intracellular cAMP suggesting the involvement of Gs protein- mediated signaling.

Exendin-4 inhibits apoptosis of human pancreatic islet endothelial cells in high glucose condition: effects on the AKT/cAMP/PKA signalling pathways

I. Miceli, E. Favaro, F. Settanni, A. Baragli, R. Granata, G. Camussi, E. Ghigo, P. Cavallo Perin, M.M. Zanone;
Internal medicine, University of Turin, Italy.

Introduction: Increased understanding of the glucoregulatory action of incretin hormones has yielded greater insight into the pathophysiology of diabetes and has led to the development of new treatments for type 2 diabetes. Specifically, it has been demonstrated that the endogenous human incretin hormone glucagon-like peptide-1 (GLP-1), the major product from intestinal proglucagon processing, decreases blood glucose by several pathways and that the normal physiologic response to GLP-1 is impaired in type 2 diabetes. Not only does it stimulate beta cell proliferation, but also enhances the differentiation of new beta cells from progenitor cells in the pancreatic duct epithelium and inhibits beta cell apoptosis. The GLP-1 receptor agonists, exendin-4, exhibits actions similar to those of GLP-1, promoting beta-cell growth, survival, insulin secretion and enhancing proinsulin biosyntheses. However, it is established that glucose toxicity is not solely restricted to beta cells, but affects also survival, proliferation and function of pancreatic islet endothelial cells, possibly contributing to beta cell function impairment and beta cell loss. We analyzed the effects of exendin-4 and the pathways involved on cultured human pancreatic islet microendothelial cells (MECs) in hyperglycemic conditions,.
Materials and methods: MECs were cultured in 28 mmol/L glucose concentration up to seven days and, in parallel, stimulated with exendin-4 (10 nM). Apoptosis was evaluated by a photometric enzyme immunoassay measuring mono- and oligonucleosomes in the cytoplasmic fraction of cell lysates as an index of DNA fragmentation, with Hoechst staining of apoptotic cells, and with assay of Caspase 3 activity. Western-blot analysis for P-Akt/Akt, P-Erk/Erk. Bcl-2, Bax were also performed. To evaluate the role of the PI3K/Akt, adenylyl cyclase and PKA pathways, treatments with the inhibitors wortmannin and LY294002, MDL12330A and KT5720 were also performed.
Results: In high glucose condition, proliferation of MECs progressively decreased and apoptosis increased, accompanied by a reduced activation of the survival signaling pathway PI3K/Akt. Incubation with exendin-4 (10 nM) inhibited apoptosis, increasing Akt and Erk phosphorylation and Bcl-2 expression and decreaseing Bax expression. The antiapoptotic effect of the peptides was blocked by inhibition of adenylyl cyclase (AC)/cAMP/protein Kinase A (PKA) and PI3k/Akt signaling pathways.
Conclusion: These results suggest that exendin-4, in addition to its effects on endocrine cells, also promote islet microendothelium survival. The survival effect involves the PI3K/Akt and (AC)/cAMP/protein Kinase A (PKA) signaling pathway. Exendin-4 could therefore represent a potential tool to improve islet vascularization and, indirectly, islet function.

Chronic treatment with taspoglutide, a once-weekly human GLP-1 analogue, prevents beta cell apoptosis, islet inflammation and fibrosis in ZDF rats

S. Uhles[1], J. Funk[2], M. Brecheisen[1], A. Benardeau[1], L. Tobalina[3], C.B. Wollheim[4], S. Sewing[1], C. Migliorini[1], E. Sebokova[1];
[1]Metabolic and Vascular Diseases, F. Hoffmann-La Roche AG, Basel, [2]Pharma Research Non-Clinical Safety, F. Hoffmann-La Roche AG, Basel, Switzerland, [3]Ipsen Pharma, San Feliu de Llobregat, Spain, [4]Department of Cell Physiology and Metabolism, University Medical Center, Geneva, Switzerland.

Background and aims: Our previous data have demonstrated that taspoglutide, a novel once-weekly human glucagon-like peptide (GLP)-1 analog, preserves islet integrity and β-cell function in ZDF rats, a rodent model of insulin resistance and Type 2 diabetes. To further explore the protective effect of taspoglutide on pancreatic islets, its effect on β-cell apoptosis, islet inflammation and fibrosis in vivo was investigated in ZDF rats after chronic treatment.
Materials and methods: Semi-quantitative immunohistochemistry analysis was performed to assess β-cell apoptosis, infiltration of inflammatory cells into the islet core and islet fibrosis on pancreatic sections of 9-week-old male ZDF rats 3 weeks after single application of taspoglutide (1 mg, s.c., formulated to mimic human exposure) or vehicle to 6-week-old ZDF rats (ZDF 6w).
Results: Disease progression in ZDF rats lead to a pronounced decrease in β-cell survival. In particular, the proportion of apoptotic β-cells increased significantly in vehicle-treated rats at the age of 9 weeks when compared to ZDF 6w ($p<0.001$). Conspicuously, the number of apoptotic β-cells correlated with the total number of β-cells per islet cross-section in the 9-week-old diabetic animals. In addition, a significant higher number of apoptotic β-cells was present in the islets located in the pancreatic head (near the duodenum) than in islets located in the pancreatic tail (near the spleen). Taspoglutide-treatment improved β-cell survival as demonstrated by a significantly reduced number of apoptotic β-cells per islet cross-section (taspoglutide: 0.06 vs vehicle: 0.19, $p<0.001$ and n.s. vs. ZDF 6w). This protective effect was even superior in the pancreatic tail. In addition, vehicle-treated ZDF rats at the age of 9 weeks demonstrated a significant increase in infiltration of inflammatory cells into the islet center and the progression of fibrosis within and in close distance to the islets when compared to ZDF 6w and this effect was more pronounced in the pancreatic head. Taspoglutide prevented this inflammatory process as demonstrated by significantly less infiltration of inflammatory cells into the islet center and prevented islet fibrosis. In analogy with the apoptosis results, prevention of fibrosis was more effective in the pancreatic tail.
Conclusion: In summary, these results demonstrate for the first time new aspects of β-cell protective effects of incretins in vivo. In particular, in ZDF rats after chronic treatment protective effects of taspoglutide, a novel once-weekly human GLP-1 analogue, on 1) β-cell apoptosis 2) islet inflammation and 3) islet fibrosis were shown.

Beta cell proliferation is impaired in the absence of survivin in the pancreas of duct-ligated adult mouse

X. Wu[1], Q. Zhang[1], C. Liu[1], K. Xu[1], X. Mao[1], T. Yang[1], H. Okada[2], M. Woo[3];
[1]Department of Endocrinology, First Affiliated Hospital of Nanjing Medical University, China, [2]Division of Signaling Biology, Ontario Cancer Institute, Toronto, [3]Institute of Medical Science, Ontario Cancer Institute, University of Toronto, Canada.

Background and aims: As type 1 and type 2 diabetes result from absolute or relative deficiencies in beta cell mass, respectively, understanding how beta cell mass is determined and can be manipulated may lead to new therapeutic options. We previously showed that transient perinatal expression of survivin,the inhibitor of apoptosis protein,is essential for pancreatic beta cell mass establishment by regulation of cell cycle progression. This study was designed to determine whether survivin was required for regeneration of beta cell mass in the pancreas of duct-ligated adult mouse.
Materials and methods: Using the Cre-loxP recombination system, we generated a rat insulin promoter (RIP)-driven survivin (also known as Birc5) knockout mouse with a specific deletion of survivin in pancreatic beta cells. Adult RIPCre^{+}survivin$^{flox/flox}$ mice and their control littermates (RIPCre^{+}survivin$^{+/+}$) were subjected to partial pancreatic duct ligation (PDL) or a sham operation, after which islet expression of survivin, beta cell function, beta cell mass, proliferation, beta cell size and apoptosis were analyzed.
Results: In control mice, PDL stimulated beta cell mass regeneration and beta cell proliferation and activated survivin reexpression in beta cells in the ligated tail of pancreas within 2-week. At day 7 post-PDL, control mice underwent significant regeneration of beta cell mass, increase of beta cell proliferation and beta cell numbers in the ligated tail of pancreas. However, targeted deletion of survivin in beta cells exhibited glucose intolerance at day 7 after PDL, with specific impairments in beta cell mass regeneration, beta cell proliferation and pAkt expression, and with larger average beta cell size and nucleus size. Although the number of beta cell clusters was markedly decreased, the mutant mice specifically exhibited an increased proportion of small beta cell clusters (one to ten beta cells) within the ligated tail of pancreas. Additionally, islet architecture, beta cell development and apoptosis were not affected by absence of survivin after PDL.
Conclusion: Our results indicate that survivin reexpression in the pancreatic beta cells after PDL is essential for beta cell mass regeneration through beta cell proliferation. The preexisting beta cells seemingly exhibit a stronger requirement for survivin than new beta cells formed by neogenesis. This study highlights the importance of preexisting beta cell proliferation as a mechanism of beta cell mass regeneration. Beta cell neogenesis, without adequate proliferation, is not sufficient to regenerate a significant amount of beta cell mass after PDL.

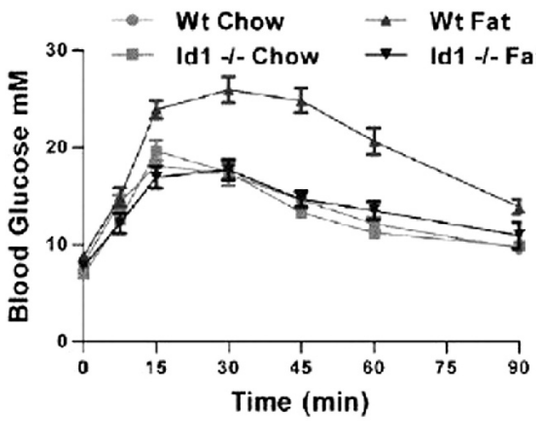
Id1 may play an important role in beta cell dysfunction in type 2 diabetes

M.C. Åkerfeldt, D.R. Laybutt;
Diabetes and Obesity, Garvan Institute of Medical Research, Sydney, Australia.

Background and aims: Pancreatic β-cell dysfunction is central to the development of type 2 diabetes (T2D). Chronically elevated glucose and lipid levels may contribute to β-cell dysfunction in T2D, although the molecular mechanisms remain unknown. In islets of diabetic db/db mice, we found that β-cell dysfunction was associated with upregulation of a transcriptional regulator, inhibitor of differentiation 1 (Id1). Id proteins are negative regulators of helix-loop-helix (HLH) transcription factors. HLH proteins are critical for β-cell development and function and therefore we investigated the role of Id1 in insulin secretion and glucose homeostasis in MIN6 cells and Id1 knockout mice.
Materials and methods: Id1 knockout (Id1-/-) and Wildtype (Wt) mice were fed *ad libitum* for 6 or 18 weeks with standard chow (8% calories from fat) or high-fat diet (45% calories from fat [lard]) followed by intraperitoneal glucose tolerance test (*ip*GTT), insulin tolerance test (*ip*ITT) or insulin secretion assay (batch incubations of isolated islets). To examine effects of increased Id1 expression on insulin secretion, Id1 was overexpressed in MIN6 cells followed by insulin secretion assay. Statistical analysis was performed by student's t-test or two-way ANOVA.
Results: Id1-/- mice were completely protected from high-fat diet-induced glucose intolerance (*ip*GTT, $P<0.001$). This was not associated with altered food intake, body weight or epididymal fat pad weight, which were similar in fat-fed Wt and Id1-/- mice. However, insulin levels during the *ip*GTT ($P<0.01$) and insulin release from isolated islets ($P<0.001$) were significantly increased in fat-fed Id1-/- mice compared to fat-fed Wt mice. This protection from diet-induced glucose intolerance in association with augmented insulin secretion was observed at 6 and 18 weeks of high-fat feeding. No differences in insulin action were observed during *ip*ITT of fat-fed Wt and Id1-/- mice, suggesting that the protection from diet-induced glucose intolerance is due to improved β-cell function rather than by changes in insulin sensitivity. No differences in glucose tolerance or insulin secretion were observed in chow-fed Wt and Id1-/- mice, indicating that deletion of Id1 enhances insulin secretion only under conditions of fat oversupply and insulin resistance. In MIN6 cells, overexpression of Id1 led to reduced glucose-stimulated insulin secretion ($P<0.05$), indicating that increased expression of Id1 is sufficient to inhibit insulin secretion.
Conclusion: An important role of Id1 in β-cell dysfunction is supported by evidence that deletion of Id1 in mice protects against diet-induced glucose intolerance and enhances insulin secretion under conditions of fat oversupply, and that increasing Id1 expression in β-cells inhibits insulin secretion. Thus, Id1 expression may contribute to β-cell dysfunction in T2D.



Blood glucose levels during *ip*GTT (2 g/kg) of Wt and Id1 -/- mice fed standard chow or high fat diets. ANOVA: P<0.001 for genotype effect in fat fed mice

Sodium glucose co-transporter type 2 knockout reduces hyperglycaemia and preserves islet function in db/db mice

R.G. Kibbey[1], M.J. Jurczak[1], A.L. Birkenfeld[1], F.R. Jornayvaz[1], H.-Y. Lee[1], R.L. Pongratz[1], X. Zhao[1], V.T. Samuel[1], J.M. Whaley[2], G.I. Shulman[1];
[1]Internal Medicine/Endocrinology, Yale University School of Medicine, New Haven, [2]Metabolic Diseases Biology, Bristol-Meyers Squibb Research and Development, Princeton, USA.

Background and aims: Defective glucose-stimulated insulin secretion by pancreatic beta-cells due to glucose-toxicity has been implicated in the pathogenesis of type-2 diabetes. Therapies that reduce hyperglycemia could therefore not only prevent complications, but could potentially preserve beta-cell function. Inhibition of the sodium-glucose co-transporter type 2 (SGLT2) is a novel insulin-independent approach to lowering plasma glucose. SGLT2 is responsible for reabsorbing the majority of filtered glucose in the kidney. Thus, reducing SGLT2 activity leads to significant loss of glucose in the urine.
Materials and methods: To determine the effects of SGLT2 knockout on glucose homeostasis, insulin action and islet function against a background of extreme insulin resistance (db/db), we characterized wild type (db/db-SGLT2$^{+/+}$), SGLT2 heterozygote (db/db-SGLT2$^{+/-}$) and SGLT2 homozygote (db/db-SGLT2$^{-/-}$) null mice by hyperinsulinemic euglycemic studies as well as with hyperglycemic clamps. Isolated islets from the mice were perifused to assess insulin secretion.

Results: Fasting plasma glucose and insulin were reduced in db/db-SGLT$^{-/-}$ mice relative to db/db-SGLT$^{+/+}$ mice (P<0.001), while there was no difference in db/db-SGLT$^{+/-}$ mice (glucose: 124 ± 8, 199 ± 15, 202 ± 20 mg/dl; insulin: 92 ± 6, 163 ± 22, 176 ± 22 μU/ml). There was no difference in body weight between genotypes, despite a 1.5-3 fold greater daily urine output and glucosuria in db/db-SGLT$^{-/-}$ compared to db/db-SGLT$^{+/+}$ mice. Nevertheless, adiposity was 5% less (P<0.01) in db/db-SGLT$^{-/-}$ mice compared to db/db-SGLT$^{+/+}$. During hyperinsulinemic euglycemic clamp studies, the glucose infusion (GINF) required to maintain euglycemia in db/db-SGLT$^{-/-}$ mice was 100% higher than db/db-SGLT$^{+/-}$ and 170% higher than db/db-SGLT$^{+/+}$ mice (P<0.01). There were no differences in muscle or fat glucose uptake suggesting that reduced hepatic glucose output and/or glucose loss in urine accounted for changes in GINF. Interestingly, *in vivo* islet function as assessed by hyperglycemic clamp studies suggested that SGLT2 inhibition may preserve islet function: AUC insulin secretion was approximately 190% greater in db/db-SGLT$^{-/-}$ mice compared to db/db-SGLT$^{+/+}$ mice (P<0.05). Lastly, perifusion studies with isolated islets demonstrated no difference in glucose stimulated insulin secretion in db/db-SGLT$^{-/-}$ compared to db/db-SGLT$^{+/+}$ mice on a per islet basis, suggesting that changes in beta-cell mass and/or islet number accounted for the increased insulin secretion during hyperglycemic clamps.
Conclusion: SGLT2 knockout reduced adiposity and prevented hyperglycemia in db/db mice. Furthermore, reduced hyperglycemia appeared to preserve overall beta-cell function *in vivo*, resulting in greater insulin secretion during the hyperglycemic clamp. Taken together, these data suggest that SGLT2 inhibition is an attractive therapeutic target for type 2 diabetes.

Deletion of beta cell Raf-1 kinase results in glucose intolerance
E.U. Alejandro, G.E. Lim, X. Hu, R. Liang, F. Taghizadeh, T. Kalynyak, J.D. Johnson;
Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

Background and aims: Regulation of glucose homeostasis by insulin depends on pancreatic beta-cell survival, growth, and function. Raf-1 kinase is a major downstream target of many growth factors that promote growth and survival of many cell types including the pancreatic beta-cells. We have previously reported that insulin protects beta-cells from apoptosis and promotes proliferation by activating Raf-1 signalling in dispersed primary mouse islets and in the mouse-insulinoma MIN6 cell line. As Raf-1 activity also regulates basal apoptosis and insulin secretion in vitro, we hypothesized that Raf-1 may play an important role in beta-cell function in vivo.
Materials and methods: To test this hypothesis, we utilized the Cre-loxP recombination system to obtain a pancreatic beta-cell specific ablation of Raf-1 kinase gene (RIPCre+/-:Raf-1flox/flox) and their littermate controls (RIPCre+/-:Raf-1wt/wt). Immunofluorescense imaging was performed on paraffin-embedded mouse pancreas sections to analyze Raf-1 localization. Quantitative PCR was performed on isolated islet RNA from RIPCre+/-:Raf-1wt/wt and RIPCre+/-:Raf-1flox/flox. Protein expression of Raf-1, B-Raf, ERK1/2, and SNARE proteins were examined by western blotting. Glucose and insulin tolerance tests were performed on RIPCre+/-:Raf-1flox/flox mice and their littermate controls.
Results: Raf-1 is expressed in various cell types in the pancreas including insulin positive cells. Of the Raf isoforms, A-Raf message levels were the highest, followed by B-Raf and Raf-1 in control mice. Beta-cell specific deletion of Raf-1 did not alter the expression of A-Raf or B-Raf message levels in RIPCre+/-:Raf-1flox/flox mice. B-Raf and Erk1/2 protein expression levels did not change in RIPCre+/-:Raf-1flox/flox mice compared to controls. RIPCre+/-:Raf-1flox/flox mice are viable, and no effects on weight gain were observed. RIPCre+/-:Raf-1flox/flox mice have increased fasting basal blood glucose levels, impaired glucose tolerance, but normal insulin tolerance compared to littermates control. Islet perifusion studies demonstrated that islets isolated from RIPCre+/-:Raf-1flox/flox mice have impaired response to both glucose and KCl, consistent with the concept that Raf-1 plays an important role in beta-cell function. To ascertain if Raf-1 function regulates the expression of the exocytotic machinery, SNARE proteins were examined by western blot. In preliminary studies with MIN6 cells, Raf-1 inhibition was associated with an impairment of glucose-stimulated insulin secretion. Furthermore, phosphorylation of synapsin-1, which is required for liberating insulin granules from the actin cytoskeleton, was also completely abrogated.
Conclusion: Together with our previous work demonstrating that Raf-1 promotes survival and proliferation, these new results suggest that Raf-1 positively regulates beta-cell function in vivo.

Function of Insm1 in mature pancreatic beta cells
S. Jia, M. Poy, C. Birchmeier;
Developmental Biology / Signal Transduction, Max Delbrück Centrum Für Molekula, Berlin, Germany.

Background and aims: Insm1 was originally isolated from a human insulinoma subtraction library and was subsequently found to be expressed in a large numbers of tumors of neuroendocrine origin as well as in mouse developing nervous systems, many developing and adult endocrine cell types, among them adult pancreatic β-cells. Mouse Insm1 is an intron-less gene, which encodes a protein of 521 amino acids that contains three proline-rich regions, five C2H2 zinc finger motifs, a SNAG motif and a nuclear location signal (NSL). Insm1 is predicted to act as a transcription factor. Our previous work showed that Insm1 is essential for differentiation of pancreatic and intestinal endocrine cells. In the pancreas of Insm1 null mutant mice, endocrine precursors are formed, but only very few insulin-positive β-cells are generated. Instead, endocrine precursor cells accumulate that express none of the pancreatic hormones. However, the function of Insm1 in mature pancreatic β-cells is still unknown
Materials and methods: To define Insm1 function in mature pancreatic β-cells, we introduced a conditional mutation into the Insm1 gene in mature β-cells. For this, we used a floxed Insm1 allele and a tamoxifen-inducible variant of cre, creER, which is expressed under the control of the insulin promoter (RIP-creER).
Results: Conditional mutation of Insm1 in mature pancreatic β-cell blocks glucose induced insulin secretion and causes hyperglycemia. However, Insm1 mutation did not ablate amino acid (e.g. Arginine) stimulated insulin secretion, and the secretory machinery appears therefore not to be defected. Whole pancreatic insulin contains are comparable between wild type and conditional mutant mice, which is consistent with β-cell mass and β-cell number. Microarray analysis shown expression of numerous genes that are important for pancreatic β-cell function is abnormal.
Conclusion: Insm1 is important for maintaining of mature pancreatic β-cell function. Deletion of Insm1 in mature pancreatic β-cells causes diabetic phenotype.

Deletion of the mitochondrial chaperone prohibitin-2 in beta cells results in beta cell apoptosis and promotes diabetes in transgenic Bet-Phb2$^{-/-}$ mice
S.M. Supale[1], T. Brun[1], I. Avril[1], A. Gjinovci[1], C. Merkwirth[2], P.L. Herrera[1], T. Langer[2], P. Maechler[1];
[1]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland, [2]Institute for Genetics, University of Cologne, Germany.

Background and aims: Prohibitins are evolutionary well conserved and ubiquitously expressed proteins having two interdependent homologues, prohibitin-1 and -2 (PHB2). They are implicated in cell cycle regulation, ROS production, cancer, obesity, and inflammation. Prohibitins form ring complexes in the inner mitochondrial membrane, thereby controlling mitochondrial dynamics, cristae remodeling and apoptosis. In pancreatic beta-cells, mitochondria are essential players in the control of metabolism-secretion coupling. Nevertheless, we lack information regarding importance of mitochondrial dynamics in general and putative role of prohibitins in particular. Here, we generated beta-cell specific *Phb-2* knockout mice (Bet-*Phb2*$^{-/-}$) to study prohibitins and mitochondrial integrity in the regulation of glucose homeostasis, islet physiology, and beta-cell mass.
Materials and methods: Bet-*Phb2*$^{-/-}$ mice were generated by crossing mice with *Phb2* allele flanked by lox-P sites (*Phb2*$^{fl/fl}$) with animals carrying the Cre recombinase driven by an insulin promoter (*Rip-Cre*). Mice thus generated (Bet-*Phb2*$^{-/-}$) were assessed by genomic PCR and immunoblotting on isolated tissues. Glucose homeostasis was characterized by glucose tolerance tests and plasma insulin levels. In-situ pancreatic perfusions were carried out to study effects of *Phb2* deletion on glucose-stimulated insulin secretion. Islet morphology, beta-cell mass, proliferation and apoptosis were studied using immuno-histochemistry. The study has been carried out along the principles of laboratory animal care.
Results: Non-fasting blood glucose showed that Bet-*Phb2*$^{-/-}$ mice were normoglycaemic up to the age of 4 weeks and then became hyperglycemic (14.6 mM, p<0.05) at 6 weeks, further developing diabetes with age and eventually causing death at the age 12-15 weeks. Bet-*Phb2*$^{-/-}$ mice grew normally until 6

weeks of age before progressive decline and weight loss. At 6 weeks, ipGTT revealed that Bet-*Phb2*$^{-/-}$ mice were glucose intolerant (AUC +133%, p<0.001) compared with littermate control (*Phb2*$^{fl/fl}$) mice. Plasma insulin levels were lower by 66% (p<0.01) during fasting and 93% (p<0.001) after glucose injection in 6-week old Bet-*Phb2*$^{-/-}$ mice. In-situ pancreatic perfusions revealed that both first and second phases of glucose-stimulated insulin secretion were markedly reduced (-76%, p<0.001 and -78%, p<0.001, respectively) in 6-week old Bet-*Phb2*$^{-/-}$ mice. Up to the age of 4 weeks, beta-cell proliferation was 3 times higher in Bet-*Phb2*$^{-/-}$ versus controls. Bet-*Phb2*$^{-/-}$ islets were disorganized at the age of 4 weeks onwards and beta-cell mass progressively declined with age.

Conclusion: These results demonstrate that prohibitin-2 is essential for beta-cell function and survival. Loss of this mitochondrial chaperone protein led to beta-cell death and diabetes. Interestingly, beta-cell proliferation could compensate apoptosis and postponed diabetes during the first 4 weeks of life of the Bet-*Phb2*$^{-/-}$ mice.

OP 29 Type 1 diabetes mellitus genetics: expression, interaction and function

169

Investigation of the expressional profiles in human pancreatic islets for candidate genes located in 40 type 1 diabetes associated regions

C.A. Brorsson, R. Bergholdt, T. Fløyel, L.A. Berchtold, A. Mellerup, J. Størling, F. Pociot;
Hagedorn Research Institute, Gentofte, Denmark.

Background and aims: Today more than 40 non-HLA regions have been demonstrated to be robustly associated with the risk of type 1 diabetes (T1D). However, the causal variants have not yet been identified for any of the genes located within these regions. For most of the genes their function in relation to the disease pathogenesis is also unknown. One way of dissecting possible roles for these genes in the pathogenesis is to investigate their expression, under cytokine stimulation in human pancreatic islets, to mimic the inflammatory process that precedes the clinical onset of T1D. Genes that change their expression can be presumed to have a functional relevance and further investigations can then be focused on these.

Materials and methods: Candidate genes were chosen from the 40 risk loci that were identified in the genome wide association scan published by the Type 1 Diabetes Genetics Consortium (T1DGC). The genes that were located closest to the association signal within each associated region were chosen for evaluation. The gene expression of 47 candidates was evaluated using custom designed Low Density Arrays (Applied Biosystems). Expression levels were measured in eight individual human pancreatic islet preparations before and after cytokine stimulation (mix of TNF-α, IFN-γ and IL-1β). Gene expression levels were normalized against the geometric mean of three different housekeeping genes and compared using the paired t-test.

Results: We detected expression in human pancreatic islets for 30 of the 49 investigated genes, of which 13 were significantly and four borderline regulated by cytokine treatment. Already well known candidate genes, such as *INS* and *IFIH1* were among the significantly regulated genes. Furthermore, among genes located in recently associated regions *IL10* (1q32), *IL7R* (5p13), *MMP19* (12q13) and *TNFAIP3* (6q23) were up-regulated whereas *CTSH* (15q25), *COBL* (7p12), *CTRB2* (16q23) and *SKAP2* (7p15) were down-regulated by cytokines.

Conclusion: Expression profiling of genes located in T1D associated regions has pin-pointed genes that are affected by cytokine stimulation in human islets, thus guiding the investigation towards their functional implication in the pathogenesis. In addition, the results demonstrate that despite that many of the investigated genes have been classified as "immune genes" they are in fact also expressed in human islets, and moreover they are affected by cytokines. Future studies involve the investigation of risk genotype-specific effects on gene expression in human lymphocytes to find out how genetic variation associated with the risk genes can affect their function and lead to a pathogenic state.

Type 1 diabetes protein network analyses combined with gene expression profiling in human islets

R. Bergholdt[1], C.A. Brorsson[1], T. Fløyel[1], L.A. Berchtold[1], A. Palleja[2], L. Jensen[2], J. Størling[1], F. Pociot[1,3];
[1]Dept of Genome Biology, Hagedorn Research Institute, Gentofte, [2]Novo Nordisk Foundation Center for Protein Research, University of Copenhagen, Denmark, [3]Institute for Clinical Science, University of Lund, Sweden.

Background: In type 1 diabetes (T1D) 40 non-HLA regions have been demonstrated to be robustly associated. For none of the regions the causal variant is known and most contain many genes. Even with the genetic contribution from these 40 regions and the HLA region we have still not explained the total genetic heritability for T1D. Novel approaches are needed to identify the causal T1D genes and to explain this missing heritability. We have identified all positional candidate genes in the 40 non-HLA T1D associated regions identified in genome-wide association studies (GWAS) and used these as input for network-based data mining analyses. For all input genes and interaction partners we performed expression profiling in human pancreatic islets.

Methods: 350 positional candidate genes were identified from non-HLA T1D associated LD regions from GWAS using NCBI databases. These genes were used as input into STRING data mining software extracting human protein-protein interaction networks enriched for input proteins. We used custom designed Low Density Arrays (Applied Biosystems) to evaluate gene expression levels of all genes identified as nodes in the networks. Expression levels were measured in eight individual human pancreatic islet preparations +/- cytokine stimulation. Gene expression levels were normalized against the geometric mean of three different housekeeping genes and compared using paired t-test.
Results: We identified 17 interaction networks containing 247 nodes, of which ~40 were input proteins from T1D associated regions. Three networks contained a significant amount of differentially regulated genes upon cytokine stimulation, whereas others contained none or only a few significantly regulated genes. These three networks highlight interesting pathways and shed light on the effect of cytokines on network level The data suggest that both classical inflammatory, but also non-inflammatory, pathways are important disease pathways.
Conclusion: We have used a novel approach to identify networks and genes of importance in T1D. Only few of the significantly regulated genes were located in T1D genetic regions identified in GWAS, so we extracted information not directly obtainable from genetic studies, i.e. GWAS. We believe this approach of combining genetic knowledge with bioinformatics and functional genomics unravels knowledge of relevance for disease pathogenesis from GWAS, which can be used to point at potential novel pathways or targets for new prevention or treatment strategies.

171

Identification of type 1 diabetes candidate genes by *in silico* phenome-interactome analysis

J. Størling[1], L.A. Berchtold[1], Z.M. Størling[2], F. Ortis[3], J. Hald[4], T. Galbo[4], K. Lage[2], C.B. Berthelsen[1], D.L. Eizirik[3], S. Brunak[2], F. Pociot[1];
[1]Dept. of Diabetes Inflammation, Hagedorn Research Institute, Gentofte, [2]Center for Biological Sequence Analysis, Lyngby, Denmark, [3]Universite Libre de Bruxelles, Brussels, Belgium, [4]Hagedorn Research Institute, Gentofte, Denmark.

Background: Type 1 diabetes (T1D) has a strong genetic background, but except for a few, the specific genes that contribute to disease remain to be discovered.
Methods: A systems biology/bioinformatics method for predicting genes involved in disease was recently developed. The method is based on *in silico* generation of protein networks and disease phenotype association. We used this "phenome-interactome protein network analysis" to identify novel T1D candidate genes. Follow-up studies involved experiments to address the functional role of predicted genes in pancreatic beta-cells.
Results: Using T1D genome-wide linkage results as input data, we performed a phenome-interactome protein network analysis. The analysis revealed 11 candidate genes including two *HLA* genes and the *INS* gene. A top-scoring candidate gene was Huntingtin-interacting protein (*HIP*)-14. No previous reports have linked *HIP14* to T1D. To explore the potential functional role of HIP14 in pancreatic beta-cells, we performed a series of experiments on different beta-cell model systems. Immuno-histochemical staining and Western blotting indicated that HIP14 is expressed in both primary and clonal beta-cells. Comparison of HIP14 expression in a beta-cell line and an alfa-cell line demonstrated that HIP14 is 2-fold higher expressed in beta-cells versus alfa-cells. Knock-down experiments with either siRNA or short-hairpin RNA against HIP14 in purified primary rat beta-cells or INS-1 cells induced apoptotic cell death suggesting that HIP14 is required for beta-cell survival. Further, knock-down of HIP14 caused a reduction in beta-cell insulin release. Consistent with a pro-survival role of HIP14 in beta-cells, inflammatory cytokines (IL-1 + IFN) known to contribute to beta-cell dysfunction and apoptosis in T1D reduced the expression of HIP14 in rat islets and INS-1 cells. In human islets, cytokines decreased HIP14 expression in 6 out of 8 donor islet preparations.
Conclusion: Using a bioinformatics/systems biology approach to predict disease candidate genes, we, among several other genes, identified HIP14 as a gene being involved in T1D. Functional studies demonstrated that expression of HIP14 is suppressed under inflammatory conditions resembling those of T1D, and that HIP14 is needed for beta-cell survival and insulin secretion.

172

Factors associated with early/childhood onset of the disease in families with type 1 diabetes. Results from the type 1 diabetes genetics consortium (T1DGC)

A.M. Wägner[1,2], A. Santana[3], J.C. Wiebe[1], M. Hernández[4], J. Nóvoa[1,2], D. Mauricio[4], T1DGC;
[1]Endocrinology, Complejo Hospitalario Universitario Insular Materno-Infantil, Las Palmas de Gran Canaria, [2]Ciencias Médicas y Quirúrgicas, Universidad de Las Palmas de Gran Canaria, [3]Matemáticas, Universidad de Las Palmas de Gran Canaria, [4]Endocrinology, Hospital Universitari Arnau de Vilanova, Lleida, Spain.

Background and aims: Families with at least 2 affected siblings have been included by the T1DGC in order to find genes associated with risk/protection for type 1 diabetes (T1D). The aim of our study was to find factors associated with early and childhood onset of the disease.
Materials and methods: Clinical information was obtained with questionnaires, serum anti-GAD and anti-IA2 antibodies were measured (RBA) in the affected siblings and HLA was genotyped (PCR-based, sequence-specific oligonucleotide probe system). Early onset of the disease was defined as onset in the lowest tertile (<6 years), whereas childhood-onset diabetes was defined as that diagnosed before the age of 15. Differences between groups were analysed with Wilcoxon-Mann-Whitney's test and chi-square. The first two siblings per family diagnosed with T1D were included in the analysis. To identify the factors independently associated with early and childhood onset, multivariate regression analysis was performed, including time since diagnosis, antibody positivity, presence of associated autoimmune diseases (AAID) and number of risk and protective HLA haplotypes as independent variables. High-risk and protective haplotypes were defined as the 4 most susceptible and protective, respectively, according to a previous report from the T1DGC.
Results: Data including unequivocal HLA haplotypes was available from 2663 families (4817 participants). Median (range) age of onset of the disease was 9 (0-49) years, time since diagnosis, 7 (0-57) years, 49.3% were female, 47.3% were positive for GADA and 47.2% for IA2A. Subjects with early onset of T1D were less frequently GADA and IA2A positive, had longer disease duration and had more high-risk HLA haplotypes. In the multiple regression analysis, male gender (OR 1.15 (1.02-1.31), p=0.019), negativity to GADA (OR 0.48 (0.42-0.54), p=2*10-16 for positivity) and IA2A (OR 0.68 (0.60-0.78), p=4.25*10-9) and time since diagnosis (non-lineal, p=2.45*10-13) were independently associated with early onset. Participants with childhood onset T1D (84%) were more frequently male, had less frequent AAID, less GADA and more IA2A positivity, less protective and more high-risk HLA haplotypes and longer time since diagnosis than participants with adult-onset T1D. In the multiple regression analysis, the following were independently associated with childhood-onset disease: male gender (OR 1.49 (1.28-1.74), p=2.35*10-7, AAID (OR 0.75 (0.60-0.92), p=0.007), GADA negativity (OR 0.35 (0.30-0.41) for positivity, p=2*10-16) and IA2A positivity (OR 1.30 (1.11-1.52), p=0.001), number of protective HLA haplotypes (OR 0.27 (0.11-0.70) per haplotype, p=0.007) and time since diagnosis (non-linear, p=0.001).
Conclusion: Early onset of T1D was independently associated with male predominance and antibody negativity at examination, whereas childhood onset disease was associated with male predominance, IA2A positivity and GADA negativity, less frequent AAID and fewer protective HLA haplotypes.

HLA and insulin genes: Bayesian networks confirm interaction between the two most important susceptibility genes in type 1 diabetes in a French caucasian population

R. Portuesi[1], B.O. Böhm[2], C. Julier[3], P. Pozzilli[1];
[1]University Campus Bio-Medico, Rome, Italy, [2]University Hospital Ulm, Internal Medicine I, Ulm, Germany, [3]Centre National de Genotypage, Evry, France.

Background and aims: Type 1 diabetes (T1D) is an autoimmune chronic disease resulting from the interaction between more or less favouring environmental factors with multiple susceptibility genes. HLA, Insulin (INS), CTLA4 and PTPN22 are considered the main T1D susceptibility genes. As many epidemiological studies have demonstrated, T1D incidence is increasing worldwide by 3.9% per year, particularly in Caucasian population of

Northern Europe. Unlike in single gene disorders, in multifactorial diseases, such as T1D, identifying the combination of causative genes is still difficult. Genetic profiles of individuals who are affected by T1D appear to change among different countries shifting from mainly high-risk genotypes towards higher percentages of median and low-risk genotypes. In a previous study we demonstrated the interaction between HLA and INS genes in an Italian population from Lazio region using the Bayesian Network approach. To confirm our previous findings, the aim of the present study was to investigate and verify in T1D the dependency and interaction between HLA and INS genes by investigating another Caucasian population.

Materials and methods: We have analyzed a database of genetic data from a French Caucasian population, the case-control cohort consisted of 868 French T1D patients (M/F 1.13, 19.63 ±14.40 yrs mean age of T1D onset) and 93 French control subjects (M/F 0.7). Diagnosis of T1D was based on the ADA classification criteria. We divided HLA alleles in high, moderate and low risk for T1D, PTPN22 alleles in susceptibility/non susceptibility alleles and INS gene alleles in susceptibility/protection. We created a Bayesian Network model trained on genetic variables and group status (T1D/control). Bayesian networks, also called belief networks, are probabilistic graphical models that represent a set of variables and their probabilistic dependencies. To gain insights into the dependency/interaction between susceptibility genes involved in T1D, we have assessed more than one gene at the time (namely HLA, INS and PTPN22 genes).

Results: We implemented a Bayesian Networks model learning the structure of the specified database, with a fixed level of significance equal to 0.05 to find out the interaction. The model showed that group status was directly influenced by HLA (p = 1.0*10^(-26)) and that there was a dependency of INS on HLA (p = 4*10^(-4)). In addition to our previous data, having separated the data group wise, the analysis of T1D patients group also highlighted the gene interaction between HLA and INS (p = 3.7*10^(-4)). No significant relation between HLA and PTPN22 (p = NS) and PTPN22 and "status group" (p = NS) was found.

Conclusion: The presence of interactions between susceptibility genes can explain why the study of a single susceptibility gene in a polygenic disease such as T1D offers limited information. Bayesian network type of analysis represents a step forward in understanding gene interactions and may offer novel clues for T1D pathogenesis. Further studies are needed to clarify the true nature of the biological interaction between HLA and INS gene alleles.

174

Functional genomics of the type 1 diabetes gene interferon-induced helicase 1-linked downstream signal mechanisms in humans

I. Szatmari[1], A. Jermendy[1], Z. Almassy[2], R. Hermann[3], and the HUNT1DGENES Study Group;
[1]CellScreen Applied Biomedical Research Center, Semmelweis University, Budapest, [2]Heim Pal Childrens Hospital, Budapest, Hungary, [3]Immunogenetics Laboratory, University of Turku, Finland.

Background and aims: In type 1 diabetes (T1D) beta cell injury develops as a consequence of interaction between a complex polygenic background and environment. More than 40 T1D loci have been identified to date, however, their functional characterization, and their assignment to specific disease endophenotypes is lacking. Recently, a non-synonymous SNP (rs1990760) in the gene encoding interferon induced helicase C containing domain 1 (IFIH1) showed an association with type 1 diabetes. IFIH1 is a cytosolic viral recognition receptor, and may provide a link between viral infections and T1D. In the present study we evaluated the variation in the gene expression profile of IFIH1, and related global gene expression profiles in response to type I interferon and a viral infection model.

Materials and methods: We compared downstream signal mechanisms in T1D children with the wild type AA and the T1D predisposing GG genotypes. Jurkat (T lymphocytic) and MonoMac (monocytic) cells were stimulated with interferon-β or/and polyinosinic acid-polycytidylic acid complex (polyI:C). Global expression profiling was carried out using high density gene expression arrays. Bioinformatics analysis was performed using HT association pattern mining, FDR significance estimation, GO and KEGG pathway annotation.

Results: Treatment of both cell lines with interferon-β resulted in a biphasic induction of IFIH1. The maximum level of IFIH1 mRNA was apparent at 8 h in Jurkat cells and 4 h in MonoMac cells, then decreased before a subsequent increase observed at 24 h postinduction in both cell lines. The expression of IFIH1 mRNA increased in a interferon-β dose-dependent manner. The temporal kinetics of IFIH1 expression after polyI:C induction differed in the two studied cell lines. In a 24 hour time frame, Jurkat cells presented a biphasic induction profile, in the monocytic cells IFIH1 mRNA levels presented a single peak. The combined treatment with IFNβ followed by polyI:C had a distinct effect. Gene network analysis results will be presented on the event.

Conclusion: In the mononuclear cell lines Jurkat and MonoMac, as a result of interferon-β/polyI:C treatment the IFIH1 mRNA level's temporal kinetic presented distinct characteristics in the first phase, but similar in long term effect. The results serve as take-off data for further studies carried out in human peripheral blood mononuclear cells, presenting basis for the analysis of the role of IFIH1 in T1D pathomechanism. The global expression profiling data, and their relation to disease pathways will be released during the presentation.

OP 30 Insulin action and glucose uptake *in vitro*

175

Insulin stimulates human brown adipose tissue glucose uptake effectively

K.A. Virtanen[1], J. Orava[1], V. Oikonen[1], T. Noponen[1], P. Nuutila[1,2];
[1]Turku PET Centre, [2]Department of Medicine, Turku University Hospital, Finland.

Background and aims: Brown adipose tissue (BAT) has been acknowledged to be noteworthy in adults but its role in metabolism is still poorly understood. The aim of this study was to investigate the effects of insulin on glucose uptake (GU) and perfusion in BAT depots confirmed by cold activation in healthy adults.
Materials and methods: We measured BAT, subcutaneous adipose tissue (WAT) and skeletal muscle perfusion and GU using ^{15}O-H_2O- and ^{18}F-FDG-PET/CT in 26 healthy normal-weighted subjects during cold exposure and either with or without insulin stimulation using euglycemic clamp in normal environment. Energy expenditure with indirect calorimetry was assessed during PET/CT studies.
Results: During cold exposure, 70% of the subjects showed BAT activation. In those cases, GU in BAT was 10-fold increased (9.1±5.1 vs. 0.9±0.4 umol/100g/min, P=0.002). Perfusion in BAT correlated with GU rates in cold (r=0.82, P<0.001) but was only doubled (from 7.5±3.7 to 15.9±4.9 vs. ml/100g/min, P<0.001) and did not explain the activation. Insulin-stimulated GU in BAT was 5-fold higher than when measured at fast in normal room temperature (4.7±2.4 umol/100g/min, P<0.001). No association was found between insulin-stimulated BAT GU and perfusion. The effect of insulin on BAT metabolic rate was close to that in skeletal muscle (6.0±2.5 umol/100g/min) while GU in WAT was increased only by 50% by insulin. Plasma norepinephrine concentrations were increased substantially during cold exposure and energy expenditure tended to be higher among the subjects with active BAT.
Conclusions: Glucose uptake in BAT is under hormonal control and can be activated by insulin close to the same extent as in skeletal muscle in healthy adult humans. This increment of metabolism is independent on perfusion. Whether dietary and hormonal activation is altered in obesity is under evaluation.

Effects of AMPK activation on glucose and energy homeostasis in leptin deficient *ob/ob* mice

R.Z. Tom, P.M. Garcia-Roves, M. Gilbert, L.Q. Jiang, A.S. Deshmukh, E. Vieira, M. Björnholm, J.R. Zierath;
Karolinska Institutet, Stockholm, Sweden.

Background and aim: AMPK is a heterotrimeric complex, composed of a catalytic subunit (α) and two regulatory subunits (β and γ), which acts as a metabolic sensor to regulate glucose and lipid metabolism. A point mutation in the γ3 subunit (R225Q) increases basal AMPK phosphorylation, while concomitantly reducing sensitivity to AMP. AMPKγ3^{R225Q} transgenic mice have increased glycogen content, enhanced mitochondrial biogenesis and are protected against dietary-induced triglyceride accumulation and insulin resistance in glycolytic skeletal muscle. We determined whether skeletal muscle-specific expression of the AMPKγ3^{R225Q} isoform prevents metabolic abnormalities in leptin-deficient *ob/ob* mice (*ob/ob*-γ3^{R225Q} mice).
Materials and methods: Glucose tolerance and tissue-specific in vivo glucose uptake were determined in lean-wild-type (WT), lean-γ3^{R225Q}, *ob/ob*-WT and *ob/ob*-γ3^{R225Q} mice. Skeletal muscle glycogen and triglyceride content, as well as lipid oxidation was biochemically assessed.
Results: Glycogen content was increased in gastrocnemius muscle from lean-γ3^{R225Q} mice (lean-γ3^{R225Q} 5.3±0.4 mg/g vs. lean-WT 3.9±0.2 mg/g; p<0.05), as well as *ob/ob*-γ3^{R225Q} mice (*ob/ob*-γ3^{R225Q} 6.2±0.6 mg/g vs. *ob/ob*-WT 3.8±0.2 mg/g; p<0.05). Glucose tolerance was unaltered in either lean-γ3^{R225Q} or *ob/ob*-γ3^{R225Q} mice versus respective WT controls. Insulin-stimulated glucose uptake in EDL muscle during the euglycemic-hyperinsulinemic clamp was increased in lean-γ3^{R225Q} mice (p<0.05), but not in *ob/ob*-γ3^{R225Q} mice. In contrast, insulin-stimulated glucose uptake in soleus, brown adipose tissue (BAT) and heart was unaltered in lean γ3^{R225Q} and decreased (p<0,05) in *ob/ob*-γ3^{R225Q} mice. Basal lipid oxidation was increased in EDL muscle from lean-γ3^{R225Q} and *ob/ob*-γ3^{R225Q} mice (p<0.05). Pharmacological AMPK activation increased lipid oxidation in EDL, but not soleus muscle from lean-γ3^{R225Q} and *ob/ob*-γ3^{R225Q} mice. Elevations in gastrocnemius muscle triglyceride content were slightly prevented in *ob/ob*-γ3^{R225Q} mice. Whole body respiratory exchange ratio was unaltered between γ3^{R225Q} mutant and WT mice.
Conclusion: The AMPKγ3^{R225Q} mutation increases skeletal muscle glycogen content and enhances basal lipid oxidation in lean and *ob/ob* mice. However these improvements are insufficient to ameliorate insulin resistance and obesity in leptin deficient *ob/ob* mice. Thus, central defects due to leptin deficiency override any positive benefit conferred by peripheral overexpression of the AMPKγ3^{R225Q} mutation to improve glucose and energy homeostasis.

Pancreatic roles for GLUT2 in human neonates evaluated by GLUT2 mutants

A. Michau[1], S. L'Hoste[2], T. Grand[2], J. Teulon[2], E. Brot-Laroche[1], P. de Lonlay[3], A. Leturque[1], M. Le Gall[1];
[1]Team 9, UMRS 872, [2]Team 3, UMRS 872, [3]Reference Center for Inherited Metabolic Disorders, Necker-Enfants Malades Hospital, University Paris Descartes, Paris, France.

Background and aims: GLUT2 is a facilitative sugar transporter; its low affinity and high capacity allow large fluxes of sugar in the liver, intestine, kidney and brain. GLUT2 is also a glucose receptor, detecting extracellular sugar and transducing a signal independent of glucose metabolism. The implication of GLUT2 in insulin secretion by beta pancreatic cells is well characterized in rodents but remains to be clarified in human. Mutations in human GLUT2 give a Fanconi-Bickel syndrome (FBS), patients suffer from glycogenosis and glucose homeostasis disorders but not from overt diabetes. A study showed that after oral glucose, young FBS patients displayed hyperglycemia and relative hypoinsulinemia, improving with age. Accordingly, GLUT2 expression in pancreatic beta cells, controversial in adults, was reported in human neonates. Neonates suffering from Congenital Hyperinsulinism syndrome (CHI) showed sever hypoglycemia due to high insulin secretion. Mutations in the pancreatic ATP-sensitive potassium channel are responsible for most characterized CHI, however 50% of cases remain unexplained and mutation in others genes are explored. Our hypothesis is that constitutive activation of GLUT2 functions could be consistent with CHI syndrome. The aim of this study was thus to evaluate the role of GLUT2 in human neonate pancreatic function investigating hGLUT2 mutants and their impact on insulin secretion.
Materials and methods: We generated by side-directed mutagenesis a panel of 6 hGLUT2 mutants. 3 single point homozygous mutations identified in FBS patients were generated to test their biological activity, they are suspected to abolish sugar transport. 3 other mutations were generated as possibly activating GLUT2 mutations (E,H,D). GLUT2 kinetic parameters were calculated by measuring the uptake of radio-labeled 2-deoxy-D-glucose in Xenopus oocytes. Insulin secretion was assayed using the insulin-secreting cell line Min6.
Results: As expected, the 3 FBS-associated mutations abolished GLUT2 transport function. Conversely, E and H mutations induced an increase in kinetic parameters of GLUT2 (lower Km, higher Vmax respectively) and D mutation decreased Vmax. Expression of these 3 mutants in Min6 cells stimulated insulin secretion at glucose concentrations inefficient in cells transfected with wild-type hGLUT2. For E mutant, insulin secretion occurred even in absence of glucose. This disqualified increased sugar transport as the single signaling event, and suggested that activation of receptor function of hGLUT2 may be in part responsible for the increased insulin secretion. Finally, we found in a pancreas sample of a CHI neonate that hGLUT2 was present in insulin positive cells, likely to play a crucial role on neonate human pancreas function.
Conclusion: With this work, we involve human GLUT2 as a direct actor in insulin secretion process not only through its transporter- but also through its receptor-function in neonates. Since activating mutations of GLUT2 can increase insulin secretion even in absence of glucose, we propose GLUT2 as a candidate gene to be sequenced in CHI patients. Modulating the receptor function of GLUT2 without affecting its transporter function that provides vital sugar may be a strategy to improve or decrease insulin production in patients suffering from metabolic diseases.

OP 30 Insulin action and glucose uptake in vitro

178

The effect of Astaxanthin, a strong antioxidant, on reactive oxygen species or insulin signaling *in vitro*

M. Ishiki, H. Ishibashi, I. Usui, M. Urakaze, K. Tobe;
First Department of Internal Medicine, Toyama University, Toyama-shi, Japan.

Background and aims: Astaxanthin, a strong antioxidant, has been reported that it has a various effects on glucose or lipid metabolism, although precise mechanism(s) of its effect on signaling pathway in the cell remains to be elucidated. Here we examined its effects on reactive oxygen species (ROS) or insulin action *in vitro.*
Materials and methods: We stimulated L6 muscle cell or 3T3-L1 adipocyte with 50 mU/ml glucose oxidase (GO) or 7.5 mM Menadione, strong ROS generators widely used in research, or 10 nM insulin respectively, along with or without 30 μM Astaxanthin. The effect of Astaxaxnthin on signaling pathway in distinct conditions was conducted by western blotting, kinase assay or RT-PCR analysis.
Results: Astaxanthin enhances insulin-induced Akt phosphorylation but does not change IRS-1 phosphorylation. Intriguingly, it enhances GO or Menadione induced Akt phosphorylation as well although both generators do not phosphorylate IRS-1. We next explored which factor(s) involves in regulating further Akt phosphorylation by Astaxanthin. We found that PP2A activity, a serine/threonine-protein phosphatase, which dephosphorylates Akt, is subtly decreased by Astaxanthin itself and slightly decreased by insulin. On the other hand, Astaxanthin significantly lowered PP2A activity decreased by insulin. We speculate that Astaxanthin regulates Akt phosphorylation induced by insulin via regulation of PP2A activity and this effect requires insulin signal input. Similarly, we also observed that GO or Menadione decreased PP2A activity, again which is lowered by Astaxanthin. Although it has been reported that PP2A activity is regulated through src by insulin, src inhibitor does not have effect on enhanced Akt phosphorylation by Astaxanthin. These results suggest Astaxanthin regulates Akt phosphorylation induced by insulin or ROS generators through the same mechanism involving PP2A activity. Next, we explored the effect of Astaxanthin on cell apoptosis in various conditions. We found that Astaxanthin strongly decreased induction of Didt3 mRNA level or JNK phosphorylation by GO or Menadione. Furthermore, Astaxanthin decreased insulin induced JNK phosphorylation. Of particular interests to other molecules involved by insulin, shc phosphorylation is decreased with Astaxanthin. Finally we examined the effect of Astaxanthin on mitochondrial function since mitochondria plays an important role for oxidative stress response in the cell. We observed that Astaxanthin induced HO -1, PGC-1α or PPARα mRNA level significantly respectively.
Conclusion: These results *in vitro* suggest Astaxanthin appears to play a role as `insulin enhancer` and prevent cell from apoptosis induced by ROS presumably by eliminating ROS with regulating of mitochondrial function. Regarding intriguing Astaxanthin`s impact on insulin signaling, it seems to promote only good effect of insulin since shc phosphorylation leading to cell proliferation, which could cause some diabetic complication, induced by insulin is rather decreased by Astaxanthin. Similar results of the effect of Astaxanthin on insulin or ROS generators signaling pathway could be due to the ROS generation by insulin as reported. Astaxanthin would be a very effective tool which improves not only abnormal glucose metabolism or cell apoptosis caused by oxidative stress but also insulin sensitivity *in vivo* as well.

Endothelin-1 acutely affects glucose metabolism in human skeletal muscle

A. Shemyakin, F. Salehzadeh, D. Duque Guimaraes, F. Böhm, E. Rullman, T. Gustafsson, J. Pernow, A. Krook;
Karolinska Institute, Stockholm, Sweden.

Background and aims: Endothelin (ET)-1 is a vasoconstrictor and pro-inflammatory peptide that may interfere with glucose uptake. The objective of the study was to investigate if exogenous ET-1 affects basal forearm glucose uptake in patients with insulin resistance (IR) and in cultured human skeletal muscle cells.
Materials and methods: Nine male subjects (age 61±3) with IR (total body glucose uptake <5.5 mg/kg/min or HOMA index >3) participated in a protocol using saline infusion followed by ET-1 infusion (20 pmol/min) for 2 h into the brachial artery. Forearm blood flow was assessed with venous-occlusion plethysmography. Endothelium-dependent (EDV) and -independent vasodilatation (EIDV) were determined. Forearm glucose uptake (FGU) was calculated from the arterio-venous plasma glucose concentration difference and plasma flow. Molecular signaling and glucose metabolism were determined in cultured skeletal muscle cells by western blot in the absence and presence of ET-1. Localization of ET receptors was characterized in human skeletal muscle tissue and cultured cells.
Results: Thirty min saline infusion did not change FGU. Infusion of ET-1 decreased FGU by 39% ($P<0.05$) from 5.8±2.0 to 3.4±0.8 μmol/min x 1000ml after 2 hour infusion. ET-1 administration decreased basal forearm blood flow by 36% (28.3±2.5 at baseline vs. 18.0±3.2 ml/min x 1000ml at 2 h of ET-1 infusion; $P<0.05$) and impaired both EDV ($P<0.01$) and EIDV ($P<0.05$). Incubation of cultured human muscle with ET-1 for 1 h increased glucose uptake in cells from subjects with normal glucose tolerance (NGT), but impaired insulin-stimulated glucose uptake in cells from IR subjects. ET-1 decreased insulin-stimulated Akt phosphorylation by 73% in NGT cells. ET_A receptor expression was detected in Western blots of cell cultures and in regions corresponding to the skeletal muscle cell membrane of skeletal muscle biopsies.
Conclusion: The study demonstrates that ET-1, in addition to attenuating endothelium-dependent vasodilatation, acutely impairs forearm glucose uptake in subjects with IR, as well as in skeletal muscle cells from IR subjects via a mechanism that seems to involve reduced Akt phosphorylation. This finding suggests that ET-1 may contribute to the development of IR.

Enhanced lipid -but not carbohydrate- supported mitochondrial respiration in PGC-1α overexpressing mice

J. Hoeks[1], Z. Arany[2], E. Phielix[1], M.K.C. Hesselink[3], P. Schrauwen[1];
[1]Human Biology, Maastricht University Medical Centre, Netherlands, [2]Cardiovascular Institute, Beth Israel Deaconess Medical Center, Boston, USA, [3]Human Movement Sciences, Maastricht University Medical Centre, Netherlands.

Background and aims: A reduced functional capacity of skeletal muscle mitochondria has been associated with type 2 diabetes mellitus. Both reductions in mitochondrial density and lower intrinsic mitochondrial function - i.e. respiration per mitochondria - have been reported in type 2 diabetic patients. Peroxisome proliferator-activated receptor-gamma coactivator 1 alpha (PGC-1α), a master regulator of mitochondrial metabolism, has also been shown to be reduced in type 2 diabetes and muscle-specific overexpression of PGC-1α results in pronounced increase in mitochondrial density. Whether PGC-1α overexpression also results in intrinsic mitochondrial adaptations is currently unknown and subject of the present study.
Material and methods: To this purpose, we isolated skeletal muscle mitochondria from 10 male, ±10 week-old muscle-specific PGC-1α overexpressing mice (PGC-1αTG) and 8 wild-type (WT) mice. Equal mitochondrial quantities were then analyzed for their oxidative capacity by high-resolution respirometry, fuelled by a carbohydrate (pyruvate) and lipid (palmitoyl-CoA plus carnitine) substrate. Additionally, we assessed mitochondrial ROS production in isolated mitochondria by electron spin resonance (ESR) spectroscopy and UCP3 protein levels by western blotting.
Results: As anticipated, the mitochondrial yield was ~4.6-fold higher in PGC-1αTG mice as compared to WT mice (40.8 ± 3.4 vs. 8.9 ± 1.6 mg/g muscle, respectively; $p<0.001$). ADP-stimulated respiration fuelled by pyruvate tended to be reduced in mitochondria from PGC-1αTG (229.8 ± 11.9 vs. 260.1 ± 9.9 nmol O2/min/mg mitochondrial protein in PGC-1αTG vs. WT, respectively; $p=0.08$). Maximal uncoupled respiration, reflecting the maximal capacity of the electron transport chain was similar in both genotypes (396.5 ± 18.7 vs. 382.4 ± 17.0 nmol O2/min/mg mitochondrial protein in PGC-1αTG vs. WT, respectively; $p=0.60$). PGC-1αTG mice displayed a pronounced augmentation of mitochondrial fat oxidative capacity, evidenced by an increased ADP-stimulated respiration (136.9 ± 4.3 vs. 77.4 ± 2.6 nmol O2/min/mg mitochondrial protein in PGC-1αTG vs. WT, respectively; $p<0.001$). Also maximal uncoupled respiration was significantly enhanced in PGC-1αTG upon palmitoyl-CoA plus carnitine (159.4 ± 6.2 vs. 103.8 ± 3.6 nmol O2/min/mg mitochondrial protein in PGC-1αTG vs. WT, respectively; $p<0.001$). Mitochondrial ROS production was similar in PGC1αTG and WT

mice, and averaged 6705 ± 441 vs. 5933 ± 393 AU in PGC1αTG and WT, respectively (p=0.33). Mitochondrial UCP3 protein levels were markedly reduced in PGC1αTG mice as compared to WT (85.9 ± 14.2 vs. 24.8 ± 6.1 AU, respectively; p<0.001).
Conclusion: Besides stimulating mitochondrial proliferation in skeletal muscle, overexpression of PGC-1α also leads to clear intrinsic mitochondrial adaptations, i.e. an enhanced capacity upon fatty acids as substrates and a decreased UCP3 content. The low levels of UCP3 are in line with previous observations in endurance-trained athletes, who are also characterized by a high fat oxidative capacity.

Vitamin D is associated with progression from impaired glucose regulation to type 2 diabetes in a UK multiethnic population
D.R. Webb[1], B.T. Srinivasan[1], L.G. Gray[2], S.A. Mostafa[1], D. Talbot[3], K. Khunti[2], M.J. Davies[1];
[1]Department of Cardiovascular Sciences, University of Leicester, [2]Department of Health Sciences, University of Leicester, [3]Unilever Corporation, Colworth, United Kingdom.

Background: Vitamin D is implicated in the aetiology of Type 2 Diabetes (T2D). Cross-sectional analyses have consistently associated plasma 25-hydroxyVitamin D concentration (VD) with measures of insulin resistance and beta-cell dysfunction but prospective data relating to progression in groups at risk of T2D are scarce. Mixed ethnicity populations with a significant south Asian representation are an excellent study group as their rates of VD deficiency and T2DM are particularly high. Our aim was to determine if Vitamin D independently predicts progression to T2D within a UK multiethnic population with Impaired Glucose Regulation (IGR).
Materials and methods: In a population based screening study (ADDITION-Leicester), people with IGR, defined as a composite of WHO categorised Impaired Fasting Glycaemia (IFG) and/or Impaired Glucose Tolerance (IGT) are offered an annual 75g-Oral Glucose Tolerance Test and cardiovascular risk assessment. Baseline and one year measurements include standard anthropometrics, fasting and 2-hour glucose estimates, VD (IDS 25(OH) D2/D3 enzyme immunoassay), together with self-reported ethnicity, physical activity (via IPAQ questionnaire) and medication use (including non-propriety preparations). Those taking vitamin D or calcium supplements were excluded from this analysis. Baseline VD was adjusted for age, sex, waist circumference, physical activity and ethnicity. Logistic regression adjusting for confounders was used to identify if VD was independently associated with progression to T2D.
Results: 1,080 people with IGR were diagnosed from a total screened population of 6,749 (16% prevalence). 624 randomly selected subjects (75.6% White European, 23.9% South Asian,) with IGR but not taking VD supplements had VD analysed at baseline, of which 583 (93.4%) attended for follow up (Median duration 425 days, inter quartile range: 393 - 462). There were no significant differences amongst attendees and non attendees in terms of age, body mass index, blood pressure or glycaemic markers. 39 (6.7%) progressed to T2D, 225 (38.6%) continued to have IGR and 319 (54.7%) reverted to normal glycaemic status. Mean unadjusted baseline VD concentration for South Asians was 21.29±12.29 ng/l vs White Europeans 58±23.88 ng/l (p<0.001). Waist circumference (P<0.05), sex (p<0.05), physical activity (p<0.05) and ethnicity (P<0.001) influenced baseline VD concentration. Subjects progressing to T2D had a significantly lower adjusted baseline VD compared to those who continued to have IGR and who reverted to normal (T2D: 50.8±20.7 vs. IGR: 60.5±19.6 vs. Normal: 62.8±18.9 P=0.001). Lower adjusted VD significantly predicted progression to T2D at 12 months (Odds Ratios: 0.98, 0.96- 0.99, P=0.001). Significantly higher progression rates were seen in the lowest tertile of Vitamin D compared to higher levels (11.1% vs. 5.1% vs. 4.1% respectively, P=0.013), this difference remained statistically significant after adjustment for confounders.
Conclusion: Vitamin D may play an influential role in the progression of metabolic disease. Our preliminary data would support the need for a randomised intervention trial exploring the glucose lowering potential of VD replacement in multiethnic Northern latitude populations at risk of T2D.

Long-term outcomes from the PREPARE (Pre-diabetes Risk Education and Physical Activity Recommendation and Encouragement) randomised controlled trial
T. Yates[1], M.J. Davies[1], J. Henson[2], S. Sehmi[2], K. Khunti[3];
[1]Cardiovascular Sciences, University of Leicester, [2]University Hospitals of Leicester, NHS Trust, [3]Health Sciences, University of Leicester, United Kingdom.

Background and aims: The PREPARE programme, a theory-driven group-based structured education programme aimed at promoting increased am-

bulatory activity through pedometer use, has been shown to be effective at promoting physical activity and improving glucose regulation in people with impaired glucose regulation (IGT) at 12-months. The present study aims to assess whether the improvements in glucose regulation were sustained at 24 months.

Materials and methods: Overweight or obese individuals with IGT were recruited from population-based diabetes screening programmes, October 2006 to April 2007, Leicester, UK. Participants were randomized to receive either an advice leaflet, n = 34; a standard 3-hour group-based structured education programme aimed at promoting physical activity (E group), n = 31; or a 3-hour structured education programme that included enhanced self-regulation through personalized steps/day goals and pedometer use (EP group), n = 33. Both intervention conditions also received brief counselling at 3 and 6 months. The original study was designed to detect a 1 mmol/l difference in 2-h glucose; follow-up was conducted at 3, 6 and 12 months. As part of a local diabetes screening programme, participants were offered an additional appointment to assess their glycaemic status at 24 months. Outcomes included fasting and 2-hour glucose, progression to type 2 diabetes (WHO criteria) and body weight; all clinical measurements and blood assays were conducted blind to allocation using standardized criteria. Differences in change from baseline were analyzed using ANCOVA modelling.

Results: 24-month follow-up data was available for 74 (76%) participants; female = 38%, South Asian ethnicity = 20%. There was no difference in demographic or biochemical measures at baseline between those who did and did not attend. Those in the EP group maintained a significant reduction in 2-h glucose (baseline = 8.7 ± 2.3 mmol/l, follow-up = 7.3 ± 2.2 mmol/l; change compared to the control group adjusted for baseline value = -1.5 mmol/l; 95% CI = -2.8 to -0.3; p = 0.01). There was a trend towards a significant reduction in fasting glucose in the EP group (baseline value = 5.6 ± 0.6 mmol/l, follow-up = 5.4 ± 0.7 mmol/l, change compared to the control group adjusted for baseline value = - 0.3 mmol/l; 95% CI = - 0.7 to 0.0; p = 0.07). There was no difference between the control and E group in glucose levels. There was no difference in body weight in either intervention group compared to the control group. The accumulative incidence of type 2 diabetes over 24 months, diagnosed at any follow-up time-point, were: control = 18%, E = 16%, EP = 6%.

Conclusion: This study suggests that a 3-hour structured education programme aimed at promoting increased physical activity through personalized pedometer use leads to sustained improvements in glucose regulation in overweight or obese individuals with IGT, despite no change in body weight. This finding highlights the importance of promoting physical activity for its own sake rather than the end-point of weight loss. As the PREPARE programme is suitable for implementation within primary care, these findings are likely to have important implications for usual health care practice.

An individual lifestyle intervention program is not more effective in changing diabetes risk and lifestyle behaviors than providing health brochures: the Hoorn Prevention Study

J. Lakerveld[1], S.D.M. Bot[1], M.J.M. Chinapaw[2], P.J. Kostense[3], G. Nijpels[1]; [1]Department of General Practice, [2]Department of Public and Occupational Health, [3]Department of Epidemiology and Biostatistics, EMGO Institute for Health and Care Research, Amsterdam, Netherlands.

Background and aims: Diabetes mellitus type 2 (T2DM) is associated with lifestyle dependent risk factors. In this study we examined the effects of a lifestyle intervention targeting the lifestyle behaviors physical activity, diet and smoking in adults at high risk of T2DM, compared to providing written information only.

Materials and methods: Adults (n= 622) with an increased risk of developing T2DM based on the ARIC risk score were randomly assigned to the intervention or control group. The intervention group received a lifestyle intervention consisting of a cognitive behavioral program provided by trained practice nurses. In a maximum of six individual counseling sessions, followed by 3-monthly booster sessions by phone, *motivational interviewing* and *problem solving treatment* were used. The program focused in particular on intrinsic motivation to change and on self-management of problems. Primary outcome measure was the T2DM risk score with age standardized at 60 years. Secondary outcome measurements were physical activity, dietary behavior and smoking behavior. Results of the baseline and 6 and 12 months follow-up measurements are reported.

Results: 536 of the 622 participants (86.2%) completed the 6 months follow-up measurements and 504 completed the 12 months follow-up (81.0%). The mean age at baseline was 43.5 years (SD 5.3) and 363 participants were female (58.4%). The mean baseline risk score of the total sample was 18.9% (SD 8.2) on the ARIC risk formula. Participants in the intervention group received 2.5 counseling sessions on average. Regression analysis based on the intention to treat principle showed no significant differences in outcomes between the intervention and the control group at both follow-up measurements, adjusted for baseline (see Table 1).

Conclusion: The lifestyle intervention was not more effective at 6 and 12 months than providing written information, in improving T2DM risk score or lifestyle behaviors in an at risk population.

Table 1. Mean baseline and follow-up values (SD) and group differences corrected for baseline (95% CI) of T2DM risk score and lifestyle behaviors

	Control group			Intervention group			Group differences	
	Baseline	Follow-up 1 (6 months)	Follow-up 2 (12 months)	Baseline	Follow-up 1 (6 months)	Follow-up 2 (12 months)	β of between group difference Follow-up 1	β of between group difference Follow-up 2
Risk score								
ARIC	18.8 (8.5)	18.0 (7.6)	17.8 (8.2)	19.0 (7.8)	18.8 (8.5)	18.5 (8.3)	0.4 (-0.3 – 1.0)	0.3 (-0.8 – 1.6)
Physical activity[1]								
light activities	31.86 (17.3)	33.37 (18.2)	31.12 (16.7)	33.9 (17.8)	32.6 (16.5)	33.3 (17.4)	-1.5 (-4.2 – 1.2)	1.0 (-1.7 – 3.7)

Effect of a diabetes prevention programme (PREDIAS) on metabolic risk factors and quality of life: results of a randomised controlled trial

B. Kulzer[1], N. Hermanns[1], D. Gorges[1], P. Schwarz[2], T. Haak[1];
[1]Research Institute of Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, [2]Department of Medicine, Gustav Carus University Dresden, Germany.

Background and aims: The objective of this randomized, prospective trial was to evaluate the efficacy of a group program (PREDIAS) aiming at lifestyle changes and weight reduction for diabetes prevention with regard to weight reduction, glycaemic parameters and quality of life.
Materials and methods: The PREDIAS program consisted of 12 lessons based on the Diabetes Prevention Program. All lessons were delivered in group sessions. Topics of PREDIAS were: assessment of own diabetes risk, motivation for weight loss, behavioural strategies for weight reduction, physical exercise and stress management. The control group (CG) received written information about diabetes prevention. Risk factors like weight, fasting glucose and lipids as well as quality of life were assessed at baseline and at a 12 month follow-up. Quality of life was measured by using the Health Survey (SF12) consisting of 12 items.
Results: A total of 182 participants were randomised (age 56.3 ±10.1 yrs; 43% female; education 13.2 ±4.1 years; BMI 31.5 ±5.3 kg/m^2; fasting glucose 105.7 ±12.8 mg/dl). At follow-up 17 participants (9.3%) were lost to follow-up. At 12 month follow-up members of PREDIAS lost significant more weight than control group members (-3.8 ±5.2 vs. -1.4 ±4.0 p=.002). Fasting glucose decreased in PREDIAS by -4.3 ±11.3 mg/dl whereas it increased by 1.8 ±13.1 mg/dl in the control group (p=.001). There was no significant effect of the prevention program with regard to lipids (Cholesterol -10.3 ±35.9 vs. -2.0 ±35.1 mg/dl p=.144; Triglycerides -35.6 ±137 vs. -2.5 ±100.3 mg/dl p=.087, HDL -1.3 ±6.9 vs. -2.2±9.4 mg/dl p.479) and blood pressure (systolic RR -4.6 ±19.1 vs. -1.0 ±16.7 mm Hg; diastolic RR -4.4 ±11.7 vs. 2.1 ±12.6 mm Hg). At baseline all study participants reported a similar quality of life score in the SF 12 than the general population (Mental Component Summary Score (MCS) 50.3 ±5.3 vs. 51.1 ±8.1 p=.13: Physical Component Summary Score (PCS) 48.2 ±6.6 vs. 47.9 ±9.7 p=.36). However at 12 month follow-up members of PREDIAS reported a significant higher MCS than the control group (51.5 ± 3.9 vs. 49.9 ±5.4 p=.04). There was no significant effect of the prevention programme with regard to the PCS (50.7 ±5.6 vs. 48.3 ±5.7 p=.19).
Conclusion: The PREDIAS prevention program was able to reduce weight and fasting glucose significantly in a 12 month follow-up. The lifestyle change with regard to weight reduction was not achieved at the expense of quality of life aspects. Although other metabolic risk factors were considerable improved, the difference between members of PREDIAS and the control group failed to reach significance. The observed improvements with regard to metabolic risk factors after 12 month are comparable to meta-analytic findings about the efficacy of diabetes prevention programs. Since PREDIAS is a group intervention it can be expected that PREDIAS has the potential to provide lifestyle interventions effectively in a less expensive way than many hitherto evaluated diabetes prevention programs, which were mainly conducted in individual settings.

Effect of pioglitazone on beta cell function and adipocyte insulin resistance in impaired glucose tolerance: results form ACTNOW

D. Tripathy, M.-A. Baneri, G. Bray, T. Buchanan, S. Clemment, M. Nicolas, P. Reaven, D. Schwenke, F. Stenz, S. Mudaliar, R.R. Henry, A. Kitabchi, R. DeFronzo; Diabetes, Medicine, University of Texas Health Science Center, San Antonio, USA.

Background and aims: Individuals with impaired glucose tolerance (IGT) are maximally insulin resistant and have lost 70-80% of their beta cell function. Thiazolidinediones have been shown to delay/prevent onset of diabetes. ACT NOW is a randomized double-blind, placebo-controlled study to examine whether pioglitazone (PIO) can prevent/delay development of type 2 diabetes mellitus (T2DM). The aim of this study was to examine whether pioglitazone prevents/delays onset of diabetes by improving beta cell function.
Materials and methods: 602 IGT subjects (FPG =105, 2-h PG [OGTT]=168 mg%;) were randomized to PIO (45 mg/day) or placebo (PLAC) and followed for 2.8 years; 427 subjects returned for final study visit. Indices of insulin secretion and insulin sensitivity were derived from the plasma glucose, insulin, and C peptide concentrations during the OGTT. The acute insulin response ($AIR_{0\text{-}10}$ min) and insulin sensitivity (S_I) also were measured with frequently sampled intravenous glucose tolerance test (FSIVGTT) in a subset. Adipocyte insulin resistance was calculated as the fasting plasma FFA x fasting plasma insulin.
Results: 50 PLAC-treated subjects developed diabetes versus 15 PIO-treated subjects (hazard ratio=0.30, 95% CI=0.11- 0.54, p<0.00001). Pioglitazone therapy significantly reduced fasting and 2-h plasma glucose. Pioglitazone improved Matsuda insulin sensitivity index (MI) (4.3 ± 0.3 to 7.7 ± 0.3, p<0.0005). The insulin secretion insulin resistance index $\Delta I_{0\text{-}120}/\Delta G_{0\text{-}120}$ x MI (3.4 ± 0.3 vs 5.4± 0.3, p<0.0005) improved in PIO treated subjects. In contrast no significant changes in Matsuda Index (4.3 ± 0.3 to 5.2 ± 0.3, p=ns) or $\Delta I_{0\text{-}120}/\Delta G_{0\text{-}120}$ x MI (3.8 ± 0.3 vs 4.2 ± 0.2, p=ns) were observed in subjects treated with PLAC. Subjects treated with PIO also had significantly greater insulin secretion/insulin resistance index from FSIVGTT (Si x AIR) than PLAC (1186 ± 113 vs 832 ± 57, p=0.005). Pioglitazone reduced basal adipocyte insulin resistance index (5.96 ± 0.4 to 3.49 ± 0.4 p < 0.005) while no change in was noted in IGT patients on PLAC (5.97 ± 0.4 to 5.57 ± 0.4, p =ns).
Conclusion: Pioglitazone (1) improved β-cell function, and insulin sensitivity in IGT subjects, and (2) improved adipocyte insulin resistance. The improvement in beta cell function and adipocyte insulin sensitivity could represent fundamental mechanisms by which pioglitazone reduces the conversion of IGT to T2DM.

Lifetime health economic benefits of type 2 diabetes prevention in high risk subjects in an Australian setting: an updated analysis based on the results of the Diabetes Prevention Program and Diabetes Prevention Program Outcomes Study

A.J. Palmer, D.M.D. Tucker;
Department of Health Economics, Menzies Research Institute, Hobart, Tasmania, Australia.

Background and aims: Metformin and intensive lifestyle interventions (ILI) were shown to reduce incidence of type 2 diabetes (T2D) versus standard care in overweight or obese subjects with impaired glucose tolerance (IGT) in the Diabetes Prevention Program (DPP) trial and Diabetes Prevention Program Outcomes Study (DPPOS), a total follow-up of 10 years. Our aim was to project the lifetime clinical and health economic outcomes to be expected from T2D prevention in high-risk subjects managed with standard care, metformin or ILI, based on the latest published results from the DPP+DPPOS.
Materials and methods: A semi-Markov, 2nd-order Monte Carlo computer simulation model was developed to project the 10-year clinical and resource utilization results of the DPP+DPPOS to patient lifetimes. Four health states were modelled: normoglycaemia (NG); IGT; T2D and dead. Subjects started in IGT and progressed to T2D or NG, at rates dependent on the treatment received. State-specific mortality rates for NG, IGT or T2D were used. We incorporated direct medical costs (from official Australian published sources and the reimbursement perspective) and Australian health utility and probability data. For each treatment arm, we calculated years free of T2D, cumulative incidences of T2D, non-discounted life expectancies, quality-adjusted life years (QALY), total lifetime costs and incremental costs per QALY gained versus standard care. Costs and QALYs were discounted at 5% annually. Univariate and probabilistic sensitivity analyses were performed.
Results: For standard care, metformin or ILI, mean (standard deviation) number of years free of T2D were 9.47 (0.08), 11.98 (0.09), 15.17 (0.11) years respectively. Cumulative incidences of T2D were 89.7% (0.2), 83.7% (0.2) and 73.4% (0.3%) for standard care, metformin or ILI respectively. Mean life expectancies from baseline age of 50 years were 27.64 (0.14), 27.95 (0.12), 28.33 (0.11) years for standard care, metformin or ILI respectively. Delayed onset of T2D led to QALY-gained of 0.12 (0.04) and 0.38 (0.05) years for metformin or ILI versus standard care, respectively. Total lifetime cost increases of $1,116 (4,338) per patient were projected for metformin versus standard care, and cost savings of $282 (4,222) for ILI versus standard care. ILI was therefore dominant to standard care, with both improvements in clinical outcomes and overall cost savings. Incremental costs per QALY gained for metformin versus standard care were $8,757. Probability of acceptance at a typical Australian willingness to pay threshold of $50,000 were 85% and 100% for metformin or ILI respectively. Results were most sensitive to probabilities of developing T2D, relative risks of mortality in each health state, and costs of implementing the interventions.
Conclusion: Based in the latest published data from the DPP+DPPOS, substantial improvements in lifetime clinical outcomes can be expected in high risk subjects treated with metformin or ILI to delay or prevent the onset of T2D. Prevention of T2D in this group of subjects is good value for money, and may even lead to long term cost savings in an Australian setting.

OP 32 Hypertension and heart failure

The effect of combining angiotensin receptor blocker and direct renin inhibitor on albuminuria in type 2 diabetic patients with nephropathy

V.I. Pankiv[1], N.V. Pasiechko[2], I.V. Pankiv[2];
[1]Preventive Endocrinology, Centre of Endocrinology, Kyiv, [2]Endocrinology, Gorbachevsky State Medical University, Ternopil, Ukraine.

Background and aims: Angiotensin receptor blocker (ARB) and direct renin inhibitor (DRI) have been shown to reduce albuminuria and preserve renal function in patients with diabetic nephropathy. Both agents are thought to confer renal protection via blockade of renin-angiotensin-aldosterone system (RAS). Simultaneous blockade of RAS at different levels with ARB and DRI may have synergistic anti-albuminuric effect compared to monotherapy. The study aims to compare the effect of combining Losartan and Aliskiren with that of administering either drug alone on 24-hour urine albumin excretion (UAE) in patients with type 2 diabetes mellitus (DM) with nephropathy.
Materials and methods: Forty-eight patients (mean age 58±9.2 years, 16 females) were prospectively studied. After a 4-week washout period, 23 patients received Losartan 100 mg once daily and 25 received Aliskiren 150 mg for 8 weeks. Following this, all 48 patients received a combination of Aliskiren 150 mg and Losartan 100 mg for 8 weeks, followed by a double dose of both drugs for another 8 weeks. Blood pressure (BP), glycosylated hemoglobin (HbA1c) and UAE were monitored.
Results: Baseline characteristics (age, BMI, duration of DM, HbAlc, BP, creatinine clearance and UAE) were similar in both groups. There was a significant reduction in mean (95% CI) UAE after 8 weeks of monotherapy [17.0% (4.2% to 31.8%) p=0.002]. The reduction in UAE was significant in patients treated with Losartan [23.8% (2.4% to 45.6%) p=0.01] but failed to reach statistical significance for patients treated with Aliskiren [11% (-7% to 29.1%) p= 0.076]. Mean BP reduction was not significantly different between these 2 groups (p= 0.66). After 16 weeks of combination therapy, there was further 11.4% reduction in UAE [(-8% to 31%), p = 0.018] while mean BP and HbA1c were not statistically different at the beginning (week 8) and end (week 24) of the combination therapy.
Conclusion: The study showed superior effect of Losartan (100 mg) over Aliskiren (150 mg) in reducing albuminuria in patients with diabetic nephropathy. The combination of both drugs showed further benefit in albuminuria reduction independent of BP control.

Glycaemic and blood pressure variability correlates with cardiovascular factors in type 2 diabetic patients

A. Di Flaviani[1], F. Picconi[1], I. Malandrucco[1], I. Giordani[1], P. Di Stefano[2], P. Maggio[3], F. Passarelli[3], F. Farina[3], G. Frajese[1], S. Frontoni[1];
[1]University of Rome Tor Vergata, [2]Medtronic Italia spa, [3]S. Giovanni Calibita Fatebenefratelli Hospital, Rome, Italy.

Background and aims: The correlation between Glycemic and Blood Pressure variability (GV and BPV) and cardiovascular risk has not been fully addressed.
Materials and methods: Therefore, the relationships between GV and BPV on one side and intima-media thickness (IMT), left ventricular mass index (LVMI), flow-mediated dilation (FMD) on the other side were evaluated in 26 DM2 patients (age 59±10 years; diabetes duration 53±58 months; HbA_{1c} 6.7±1.3%) on diet and/or metformin, no hypotensive treatment or complications. All subjects underwent 24-h continuous glucose monitoring: GV was calculated as Mean Amplitude Glucose Excursion (MAGE), Coefficient of Variation (CV), CONGA-1 and 2. From 24-h BP monitoring, CV systolic and diastolic BP (CV SBP and DBP) and the delta between nocturnal and diurnal BP [>10%: Dippers (D); <10%: Non-Dippers (ND)] were also calculated.
Results: IMT and LVMI were significantly increased in ND vs. D (0.77 ± 0.08 vs. 0.68 ± 0.13; p= 0.04 and 62 ± 23 vs. 50 ± 19 p= 0.047). All patients displayed a negative correlation between LVMI and delta SBP (r=-0.48 p= 0.02); while a positive correlation was observed with CONGA 1 and 2 (r= 0.54 p=0.005 and r= 0.65 p=0.0005, respectively). A negative correlation was observed between IMT and delta SBP and DBP (r= -0.42 p= 0.036 and r= - 0.54 p= 0.005, respectively) while such correlation was absent with GV indexes. Finally a negative correlation was found between CONGA 1 and FMD (r= -0.42 p= 0.032).
Conclusion: Our data show that glucose excursions and BP variability significantly impact on endothelial function and cardiovascular damage in patients with short duration of disease and optimal metabolic control.

189

Different impact of type 2 diabetes mellitus and essential hypertension on aortic, carotid and peripheral vascular stiffness

G.A. Daniele[1], L. Pucci[1], D. Lucchesi[1], R.M. Bruno[2], L. Ghiadoni[2], E. Storti[1], E. Russo[1], C. Bianchi[1], S. Taddei[2], R. Miccoli[1], S. Del Prato[1], G. Penno[1];
[1]Endocrinology and Metabolism, [2]Internal Medicine, University of Pisa and Azienda Universitaria Ospedaliera Pisana, Pisa, Italy.

Background and aims: Diabetes and hypertension both accelerate vascular aging. Arterial stiffness an emergent biomarkers of cardiovascular disease, increases with age and in the presence of main cardiovascular disease risk factors, such as hypertension, diabetes and lipid disorders. Pathologic stiffening of large arteries with advancing age and risk factor exposure predominantly involves the elastic aorta and carotid arteries. Aim of this study was to evaluate the impact of type 2 diabetes, hypertension, and their combination on aortic, carotid and peripheral arteries stiffening.
Materials and methods: A total of 114 subjects were enrolled: 18 normotensive subjects (NT), 37 hypertensive individuals (HT), 20 diabetic normotensive (DMNT), and 39 diabetic hypertensive (DMHT). Applanation tonometry was used to measure aortic (carotid to femoral) and peripheral (carotid to radial) pulse wave velocity (aPWV and pPWV, respectively). Common carotid intima-media thickness (IMT) and carotid diameter were obtained by B-mode ultrasound image sequences, using the real-time computerized contour-tracking system "Carotid Studio". Common carotid stiffness (CCS) was determined from stroke change in lumen area and local pulse pressure obtained by applanation tonometry.
Results: Hypertensive groups (HT and DMHT) have similar systolic and diastolic blood pressure values and lipid parameters; diabetic subjects (DMNT and DMHT) have similar HbA1c levels and lipid profile. Peripheral pulse wave velocity (pPWV) was superimposable in all groups. On the contrary, aPWV significantly increased from NT (7.2±1.0 m/s) to HT (8.1±1.4 m/s) and DMNT (8.2±0.8 m/s), reaching the highest values in the DMHT group (10.6±1.9 m/s; Kruskal-Wallis, p<0.001). Common carotid stiffness (CCS) behaved similarly (NT 6.0±0.7 m/s, DMNT 6.5±1.2 m/s, HT 6.6±1.2 m/s, DMHT 7.3±1.2 m/s; Kruskal-Wallis, p<0.01). The presence of hypertension carried a higher risk of having increased (above the median value) aPWV (OR: 6.9; 5-95% confidence interval: 1.9-24.8), common carotid stiffness (OR: 2.8; 5-95%CI: 1.-1-7.4), and carotid diameter (OR: 3.9; 5-95%: 1.4-10.6), regardless of age and diabetes, while the differences were not significant for pPWV and IMT. The presence of diabetes carried a higher risk of having increased (above the median) aPWV (OR: 9.6; 5-95%CI: 3.3-27.2), and IMT (OR:2.7; 5-95%CI: 1.1-6.6), , regardless of age and hypertension, while the differences were not significant for pPWV, carotid diameter and common carotid stiffness.
Conclusion: Both type 2 diabetes and hypertension are associated with increased aortic PWV, and their combination induces an even greater aortic stiffening. Hypertension is characterized by vascular stiffening at both the aortic and carotid level. In contrast, type 2 diabetes is associated only with increased aortic PWV. The two conditions also differ for carotid remodeling characteristics, since hypertension determines carotid dilation while type 2 diabetes is associated with carotid wall thickening.

190

Risk factor control in patients with type 2 diabetes and coronary heart disease

A.-M. Svensson[1], S. Gudbjörnsdottir[2], B. Eliasson[2], K. Eeg-Olofsson[2], B. Zethelius[3], J. Cederholm[3];
[1]Center of Registers Västra Götaland, Göteborg, [2]University of Gothenburg, [3]Uppsala University, Sweden.

Background and aims: Patients with type 2 diabetes have a markedly increased risk of coronary heart disease (CHD), and the long-term prognosis after a CHD event is worse in diabetic than in non-diabetic patients. We assessed risk factor control in patients with type 2 diabetes and CHD from the Swedish National Diabetes Register (NDR).
Materials and methods: Cross-sectional study of patients with first incidence of CHD (myocardial infarction, unstable angina, percutaneous coronary intervention and/or coronary artery bypass graft) 1-2 years before examination, aged 18-79 years: 666 examined in 2002, 1414 examined in 2005, and 2557

examined in 2008. HbA1c analyses were quality assured nationwide by regular calibration. Patients with LDL-cholesterol (LDL-C) data available were around 70% of all due to missing data. Significance was analysed by GLM regression, adjusting for age and sex.
Results: As shown in Table 1, mean HbA1c, blood pressure (BP) and LDL-C decreased across the 6-year period from 2002 to 2008, while mean BMI was unchanged and as high as 30 kg/m^2. Achievement of the treatment targets HbA1c <7%, BP ≤130/80 mmHg and LDL-C <2.5% improved considerably across the 6-year period, and were 56%, 48% and 79% in 2008. Patients examined in 2008 within intervals of HbA1c <7%, 7.0-7.9% and ≥8% were 56%, 27% and 17%, and those within intervals of systolic BP (SBP) <130, 130-139 and ≥140 mmHg were 36%, 26% and 38%. Use of antihypertensive drugs, aspirin (ASA), and especially lipid-lowering drugs increased across the 6-year period, and were as high as 96%, 87% and 90% in 2008. A high prevalence of adverse lifestyle characteristics prevailed during the 6-year period, and in 2008 the frequency of obesity (BMI ≥30 kg/m^2) was 44%, while 45% performed physical activity <3 times/week, and 20% of patients with age <65 years were smokers.
Conclusion: Control of HbA1c, BP and LDL-C improved significantly across the 6-year period from 2002 to 2008. Although fewer patients available in 2002, significant improvement was also seen for BP and LDL-C from 2005 to 2008. In 2008, treatment targets were achieved by more than half of patients for HbA1c, and by 70% for LDL-C. Although barely half achieved BP ≤130/80 mmHg, only one-third had systolic BP ≥140 mmHg. However, a high prevalence of adverse lifestyle characteristics prevailed. Evidence-based therapy with professional lifestyle intervention seems necessary for further improvement in secondary prevention.

Table 1. Risk factors in patients with type 2 diabetes and CHD

	Examination year			P trend	P 2005

Type 2 diabetes significantly modulates the impact of low left ventricular ejection fraction on the risk of cardiovascular events
S. Greber[1], C.H. Saely[1,2], P. Rein[1,2], A. Vonbank[1,2], T. Gansch[1], C. Boehnel[1,2], V. Jankovic[1,2], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Prinicpality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: The prevalence of coronary artery disease and of congestive heart failure is high in patients with diabetes. In the present study we aimed at prospectively investigating the impact of the left ventricular ejection fraction (LVEF) and of angiographically verified coronary artery disease (CAD) on the risk of cardiovascular events in patients with type 2 diabetes (T2DM) and in non-diabetic subjects.
Materials and methods: Cardiovascular events were recorded over 8 years in 629 consecutive patients undergoing coronary angiography for the evaluation of established or suspected stable CAD. At the baseline angiography, significant CAD was diagnosed in the presence of significant coronary stenoses with lumen narrowing ≥50%, and the baseline LVEF was determined invasively by ventriculography.
Results: The baseline prevalence of significant CAD was higher (68.6% vs. 55.5%; p = 0.006) in patients with T2DM (n = 137) than in non-diabetic subjects (n = 492); the baseline LVEF was similar in these two patient subgroups (65±15% vs. 67±15%; p = 0.253). Prospectively, significant CAD (HR = 2.07 [1.50-2.88]; p <0.001) and the LVEF (standardised HR = 0.79 [0.71-0.88]; p <0.001) after multivariable adjustment both proved significantly predictive of caridiovascular events in a mutually independent manner. The incidence of vascular events was significantly higher in patients with T2DM than in non-diabetic subjects (43.8% vs. 30.1%; p = 0.003). In analyses with respect to the diabetes status, the LVEF strongly and significantly predicted cardiovascular events in non-diabetic subjects (HR = 0.72 [0.62-0.82]; p <0.001) but not in patients with T2DM (1.00 [0.75-1.22]; p = 0.711). An interaction term LVEF*T2DM was significant (p = 0.047), indicating that the cardiovascular risk conferred by a low LVEF was significantly higher in non-diabetic subjects than in patients with T2DM. The presence of significant CAD proved significantly and independently predictive of vascular events both in non-diabetic subjects and in patients with T2DM (HRs 1.84 [1.26-2.67]; p = 0.001 and 2.45 [1.18-5.06]; p = 0.016, respectively).
Conclusion: From the results of this 8-year prospective cohort study we conclude that T2DM significantly modulates the cardiovascular risk conferred by a low left ventricular ejection fraction.

192

Predictors of incident heart failure in community-dwelling older adults with diabetes mellitus
S. Akter[1,2], K. Karatzidou[3], C. Adamopoulos[3], M. Mujib[4], Z. Hassan[5], L. Ali[1,2], A. Ahmed[6];
[1]Department of Biochemistry and Cell Biology, BIRDEM, Dhaka, [2]Dept of Biochemistry, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh, [3]Papageorgiou General Hospital, Thessaloniki, Greece, [4]University of Alabama at Birmingham, Birmingham, USA, [5]Department of Physiology & Molecular Biology, BIRDEM, Dhaka, Bangladesh, [6]Medicine, University of Alabama at Birmingham and VA Medical Center, Birmingham, USA.

Background and aims: Type-II diabetes mellitus (DM) is a major risk factor for heart failure (HF). However, little is known about the risk factors for HF in those with DM. We used public-use copies of the Cardiovascular Health Study (CHS) datasets, obtained from the United States National Institutes of Health, to examine the predictors of HF in older adults with DM.
Materials and methods: Of the 5795 CHS participants, ≥65 years, 5461were free of baseline HF. Of these, 862 had baseline DM (based on past history and baseline fasting blood glucose ≥126 mg/dL) and 963 had baseline coronary artery disease (CAD). Multivariable-adjusted Cox regression models were used to determine predictors of centrally-adjudicated incident HF among those with DM during over 12 years of median follow-up. Considering that DM is considered CAD-equivalent, we repeated our analysis in a cohort with baseline CAD.
Results: Participants with DM had a mean (±SD) age of 73 (±5) years, 50% were women, and 24% were African American. Those with CAD had a mean (±SD) age of 74 (±6) years, 45% were women, and 15% were African American. Incident HF occurred in 272 (32%) and 324 (34%) of participants with DM and CAD respectively. Significant predictors of incident HF among those with DM and in those with CAD are presented in Table.
Conclusion: Community-dwelling older adults with DM had similar incidence and risk factors for new-onset HF as those with baseline CAD. Management of modifiable risk factors such as smoking and systolic blood pressure may provide opportunities for reducing risk of incident HF among both high-risk populations.

Table. Predictors of incident heart failure in older adults with diabetes mellitus (DM) and without DM but with coronary artery disease (CAD)

Variable	With baseline DM		With baseline CAD	
	Adjusted HR (95% CI)	P value	Adjusted HR (95% CI)	P value
Age 75 year and older	1.53 (1.8-2.00)	0.001	1.77 (1.41-2.23)	<0.001
Female	0.89 (0.69-1.15)	0.383	0.71 (0.55-.91)	0.008
Current smoking	1.55 (1.02-2.36)	0.038	1.77 (1.24-2.51)	0.001
Systolic blood pressure, mm Hg	1.02 (1.02-1.03)	<0.001	1.01 (1.00-1.01)	0.005
Baseline coronary artery disease	2.20 (1.68-2.88)	<0.001	---	---
Baseline diabetes mellitus	---	---	1.71 (1.22-2.39)	0.002
Serum creatinine, mg/dL	1.25 (1.06-1.48)	<0.001	---	---
Serum uric acid, mg/dL	1.13 (1.04-1.23)	0.003	1.14 (1.06-1.23)	0.001
Left ventricular systolic dysfunction	2.13 (1.50-3.04)	<0.001	1.54 (1.17-2.02)	0.002

OP 33 HbA_{1c} for diabetes mellitus diagnosis: need for reassessment?

193

A comparison of performance from using two HbA_{1c} cut-points (a 'rule-in, rule-out' spectrum) and one HbA_{1c} cut-point to detect type 2 diabetes in a multi-ethnic cohort

S.A. Mostafa[1], K. Khunti[2], D.R. Webb[1], B. Srinivasan[1], L.G. Gray[2], M.J. Davies[1]; [1]Diabetes Research Unit, [2]Health Sciences, University of Leicester, United Kingdom.

Background and aims: HbA1c≥ 6.5% has been recommended as a diagnostic tool to detect people with Type 2 Diabetes Mellitus (T2DM). However, using HbA1c≥ 6.5% leads to discordance in people detected with T2DM from using an oral glucose tolerance test (OGTT). Therefore, using two HbA1c cut-points has been suggested to reduce the number of false positives/negatives: the first to 'rule out' T2DM (HbA1c ≤5.5%) and the second to 'rule in' T2DM (HbA1c≥ 7.0%). Those with HbA1c 5.6-6.9% could have T2DM, especially if 6.5-6.9%, and may need a further glucose test for diagnosis. The aim of this study was to compare detection rates for T2DM using (a) HbA1c≥ 6.5% or (b) the 'rule-out, rule in spectrum' and to determine the optimal cut-points in our multi-ethnic cohort.
Materials and methods: Analysis of 8696 previously undiagnosed primary care adults aged 40-75 years from the LEADER cohort, a combination of two systematic screening programmes. Participants underwent an OGTT and had HbA1c measured from 2002-2008 in Leicestershire, UK. T2DM was diagnosed according to WHO 1999 criteria.
Results: Use of an OGTT detected 291 (3.3%) people with previously undiagnosed T2DM. Using HbA1c≥6.5% to detect T2DM produced a sensitivity/specificity/positive predictive value (PPV)/negative predictive value (NPV) of 62.1%/97.7%/44.8%/98.9% in white Europeans and 78.9%/92.8%/36.2%/98.8% in south Asians. Using ROC curve analysis, the single optimal HbA1c cut-point for detecting T2DM was ≥ 6.1%, (sensitivity/specificity: 83.0%/87.8%) in white Europeans and ≥ 6.3% (sensitivity/specificity: 87.9%/85.5%) in south Asians. 'Rule-out, rule-in' spectrum: HbA1c ≤5.5% produced a high sensitivity/negative predictive value (NPV) of 98.4%/99.9% in white Europeans and 98.9%/99.7 in south Asians. HbA1c≥ 7.0% produced high specificity of 99.6% and 98.8% in white Europeans and south Asians respectively, however produced lower PPV of 76.0% and 68.1% respectively. Furthermore, 5115 (58.8%) people in the total cohort had HbA1c 5.6-6.9%, and 4793 (55.1%) people with HbA1c 5.6-6.4%. Using an alternate higher 'rule-out' cut-point of HbA1c ≤5.8% maintains a high sensitivity/NPV of 91.8%/99.6% in white Europeans and 97.9%/99.8% in south Asians; a lower 'rule-in' cut-point of HbA1c≥ 6.8% has a specificity/PPV of 99.4%/69.8% and 97.2%/53.6% in white Europeans and south Asians. The remaining spectrum of HbA1c 5.9-6.7% detects fewer people, n=2505 (28.2%).
Conclusion: The optimal HbA1c cut-point to detect T2DM studied was lower than HbA1c of 6.5% in both ethnic groups. Using a two cut-point 'rule-in, rule out' spectrum to detect T2DM appears to have better performance than using HbA1c≥ 6.5% in isolation in our multi-ethnic cohort. However, as over 50% of this cohort had HbA1c values between 5.6-6.9%, many people may require a subsequent glucose test on a second visit, involving fasting, which could be impractical to implement. Within our cohort, a better two cut-point spectrum of HbA1c ≤5.8% and HbA1c≥ 6.8% maintains high sensitivity/specificity/NPV and a reasonable PPV. Furthermore, using these cut-points, approximately one-quarter of the cohort would require a subsequent glucose test, which is more feasible to implement in clinical practice.

194

Moving to the new HbA_{1c} diagnostic criteria has a deep impact on prevalence of gluco-metabolic abnormalities among high-risk Spanish population

J.J. Cabre[1], B. Costa[1], F.X. Cos[1], F. Barrio[1], J.L. Piñol[1], C. Castell[2], J. Lindström[3], N. Barengo[4], J. Tuomilehto[4], DE-PLAN-CAT Research Group; [1]Primary Health Care Division, Jordi Gol Primary Care Research Institute, Reus & Barcelona, [2]Department of Public Health, Barcelona, Spain, [3]Diabetes Prevention Unit, Helsinki, [4]Department of Public Health, Helsinki, Finland.

Background and aims: Diabetes screening in risk individuals is usually based on the detection of hyperglycemia through an increase in fasting plasma glu-

cose (FPG) or 2-hour post-load glucose (2hPG) in the oral glucose tolerance test (OGTT). The American Diabetes Association (ADA) has recently authorized the use of A1C as a diagnostic criteria for diabetes and other glucose abnormalities. To investigate the concordance between conventional 2hPG and/or FPG diagnostic criteria and the proposed new A1C criteria for diabetes, results from an active public health program (DE-PLAN) in Catalonia (Spain) were used.

Materials and methods: Non-diabetic individuals aged 45-75 y. were evaluated by general practitioners in 18 primary health care centres. They have been first screened using the FINDRISC questionnaire. A 2-hour oral glucose tolerance test plus A1C test (NGSP/DCCT rules) were simultaneously performed yearly.

Results: By January 2010 a total of 2287 blood test results have been recorded corresponding to 1144 subjects: 65% women; age=61.4 years; BMI=29.9 kg/m²; 68% with a FINDRISC score ≥12 points (moderate, high or very high risk). Diagnoses by 2hPG were: 1482 (64.8%) normal glucose tolerance (95% CI: 62.8-66.7), 609 (26.6%) prediabetes (20.7-25.6) and 196 (8.6%) diabetes (7.7-11.2). FPG-based findings were: 1572 (68.7%) normal FPG (66.8-70.6), 652 (28.5%) prediabetes (26.7-30.4) and 63 (2.8%) diabetes (2.2-3.5). Findings by A1C were: 1906 (83.4%) normal A1C *[<5.7%]* (81.7-84.8), 350 (15.3%) prediabetes *[5.7-6.4%]* (13.9-16.8) and 31 (1.3%) diabetes *[≥6.5%]* (0.9-1.9). Among the 201 diabetic diagnoses according to either the 2hPG or the A1C criteria, only 26 (12.9%) were classified as diabetic with both criteria (2hPG and A1C, *k* value=0.29). Likewise, only 19 out of 75 diabetic diagnoses according to either the FPG or the A1C criteria (25.3%) were classified as diabetic with both FPG and A1C (*k*=0.39). No differences in main phenotypes (age, sex, BMI, WC and risk score) were found between subjects who remained and did not remain diabetic by both criteria glucose and A1C. The overlap index between prediabetes diagnoses (2hPG / FPG vs. A1C) was 20.3%/27.2% (*k*=0.16/0.28, respectively).

Conclusion: To apply the new A1C diagnostic criteria evidenced a dramatic decrease in diabetes prevalence among this high-risk population by the FINDRISC. Overall, prediabetes and diabetes-specific concordances were very poor. A1C alone seems to be not advisable to screen for gluco-metabolic abnormalities among the high-risk Spanish population.

195

Comparison of HbA_{1c} and OGTT in the diagnosis of diabetes in a high-risk population. The HUNT-DE-PLAN Study, Norway

K. Midthjell[1], C.M.Y. Lee[2], C. Platou[1], S. Colagiuri[2];
[1]Institute of Community Medicine and General Practice, HUNT Research Centre, Levanger, Norway, [2]Boden Institute of Obesity, Nutrition and Exercise, Sydney, Australia.

Background and aims: Due to more standardized methods of measuring HbA_{1c} and reports showing an association between diabetes complications and HbA_{1c} in persons without manifest diabetes, an HbA_{1c} of 6.5% has been introduced as a diagnostic criterion for diabetes. Those with HbA_{1c} 6.0-6.4% are recommended preventive measures. We wanted to compare the OGTT and HbA1c diagnostic criteria in persons defined at increased risk of diabetes.

Materials and methods: The third HUNT Survey was performed in 2006-2008, examining 50406 persons ≥20 years of age (54% of those invited). The population is almost exclusively Caucasian. All participants were asked to complete the FINDRISC questionnaire. In all 9.9% had a FINDRISC score of 15 or more corresponding to at least a 30% risk for diabetes in the next ten years. All defined in risk were invited to a follow-up study including an OGTT and HbA1c measurement. Glucose was measured in serum and HbA1c by a standard and continuously validated method, both at Levanger Hospital.

Results: In total 2645 persons participated in this follow-up study. The OGTT identified 254 (9.6%) with diabetes, 446 (16.9%) with impaired glucose tolerance (IGT) and 217 (8.2%) with impaired fasting glucose (IFG). Mean HbA_{1c} (SD) was 6.4 (0.7) for those with diabetes, 5.8 (0.5) for IGT and 5.8 (0.4) for IFG. The proposed new HbA1c diagnostic criterion defined 170 (6.5%) with diabetes and 17% (450) in the 6.0-6.4% zone. Of the 170 with HbA1c defined diabetes, 100 had OGTT defined diabetes and 167 of the 450 in the HbA1c risk zone had IGT/IFG.70 people had diabetes and 283 persons were at increased risk only by the HbA1c criterion, compared with to 154 with diabetes and 496 with IGT or IFG by the OGTT. Among those with diabetes according to WHO criteria 60.7% had an HbA1c below 6.5%.

Conclusion: The overlap between the 1999 WHO criteria and the proposed new HbA1c criterion for diabetes was poor in this geographically defined Caucasian population. The new criteria do not strictly define a risk zone, but the overlap between those with HbA1c 6.0-6.4% and those with IGT/IFG was also poor.

196

Diagnosis of abnormal glucose levels in patients at high risk for the development of diabetes: A comparison of the oral glucose tolerance test and measurement of HbA_{1c} following the American Diabetes Association recommendations 2010

E. Cosson[1,2], M. Nguyen[1,2], E. Hamo Tchatchouang[1,3], I. Banu[1,3], S. Chiheb[1,3], P. Valensi[1,3];
[1]Jean Verdier Hospital, Bondy, [2]UMR U557 INSERM U1125 INRA, Bobigny, [3]IMAGE Center, Bondy, France.

Background and aims: American Diabetes Association have published in 2010 precise recommendations (ADA 2010) about (i) the population to be screened for dysglycemia, (ii) the diagnostic criteria for intermediate hyperglycemia (IH) and diabetes which include glucose values during oral glucose tolerance test (OGTT) and A1c and (iii) the patients to be considered for metformin treatment (those with both impaired fasting glucose and impaired glucose tolerance, or those with A1c ≥6%). The aim of the study was to evaluate diagnostic strategy with OGTT and/or A1C criteria.

Materials and methods: A total of 1157 patients (962 women; body mass index 37.0±7.2 kg/m²; 41.2±13 years old) fulfilling the ADA 2010 criteria to be screened and who had not been diagnosed for diabetes previously underwent an oral glucose tolerance test (OGTT) and measurement of A1c. They were assessed for diabetes risk score (Findrisc and DESIR score) and UKPDS coronary risk score.

Results: Based on OGTT and A1c respectively, 76 and 113 patients had diabetes; 307 and 299 patients had IH; and 130 and 255 patients would have been eligible for treatment with metformin. The sensitivity/specificity of A1c ≥6.5% for the diagnosis of diabetes according to OGTT were 45.9/92.0%. In patients with A1c <6.5%, the sensitivity/specificity of A1c 5.7-6.4% for the diagnosis of IH were 59.9/56.2%. Diabetes risk scores and UKPDS risk score were the highest in the 130 patients with both an abnormal OGTT and an A1c ≥5.7%.

Conclusion: OGTT and A1c are both considered as relevant diagnostic criteria for dysglycemia as they correlate with retinopathy and the risk for developing diabetes. We show in a population who should be screened that choosing the A1c strategy rather than the OGTT strategy leads to diagnose more diabetes and to treat more patients with metformin, although the consistency of both diagnostic criteria is low (for example, 1/3 of the patients with A1c ≥6.5% have a normal OGTT). The patients who have the highest *a priori* risk of diabetes and cardiovascular disease are those with an abnormal OGTT associated with an A1c≥5.7%.

197

Hemoglobin A_{1c} in a population with pre-diabetes, diagnosed and previously undiagnosed diabetes

J.M. Boavida[1,2], L. Gardete-Correia[3], S. Massano-Cardoso[4], C. Mesquita[3], J.F. Raposo[3];
[1]Portuguese Society of Diabetology, Lisbon, [2]Portuguese Diabetes Programme, Directorate General Health, Lisbon, [3]Portuguese Diabetes Association, Lisbon, [4]Hygiene and Social Medicine Intitute, Coimbra, Portugal.

Background and aims: Diabetes is a serious public health problem with epidemic characteristics. Diabetes diagnosis is based on the values of fasting plasma glucose and on the Oral Glucose Tolerance Test (OGTT). Recently, determination of A1c has been proposed for the diagnosis of "pre-diabetes" and diabetes. To analyze the reliability of screening for "pre diabetes" and undiagnosed type 2 diabetes using A1c values. To obtain information regarding A1c distribution in a representative population sample including subjects without diabetes, with diagnosed and previously undiagnosed diabetes, and with "pre diabetes".

Materials and methods: A randomized study was performed to determine the prevalence of diabetes in Portugal (PREVADIAB) covering 5,167 people randomly selected across the country, according to the population distribution. Diabetes prevalence was 11.7% between 20 and 79 years (previously diagnosed and undiagnosed). A1c was determined in all subjects. A1c data

were analyzed according to the recommendations of the "International Expert Committee Report on the Role of the A1c Assay in the Diagnosis of Diabetes" ADA/EASD/IDF (diabetes >= 6.5% and "pre-diabetes" > 5.7% and <6.4%).
Results: Excluding people who had a previous diagnosis of diabetes, 96.8% (CI 95%: 96.5% to 97.5%) of the population had A1c <6.5%. When the remaining 3.2% with A1c >= 6.5 were tested with an OGTT, 65% had undiagnosed diabetes, 29% had "Pre-Diabetes" and 6% had no diabetes criteria. 30,0% of previously undiagnosed people had A1c levels <6.5% (CI 95%: 23.6% to 36.4%). Thus, this method would not have allowed the diagnosis of 30,0% of cases of diabetes. Looking at metabolic control in people with previously diagnosed diabetes, we found that 34% had A1c values under 6.5%, 69.7% had values <7% and 15.4% had values > 8%. Analyzing A1c values in people with Impaired Fasting Glucose (IFG), 29.9% had values >= 6.5% and 98% values <7%, while in people with Impaired Glucose Tolerance (IGT) 29.7% had values >= 6.5% and 99.2% <7%. According to the criteria proposed by the ADA/EASD/IDF and analyzing the total population of PREVADIAB we verified that in the group of people with A1c values, <5.7%, 2.9% of people had diabetes. With A1c between 5.7% and 6.4%, 13.9% of people had diabetes and A1c values >= 6.4%, 86.5% of people had diabetes. "Pre-diabetes" was present in the three levels, mainly in the group with A1c values between 5.7% and 6.4% (30.0% of the group).
Conclusions: Using A1c > 6.4% as a means of diagnosis, a large number of people without previous diagnosis of diabetes (30,0%) would not be diagnosed. In the population with A1c values between 5.7% and 6.4% we found that 13.9% had diabetes, 30.0% had "pre-diabetes" and 56.1% had normal glycoregulation. Thus we should be cautious using A1c for diagnosis. In our opinion, the use of fasting glucose and OGTT remains pertinent.

198

Discordance between fasting glucose-based and hemoglobin A_{1c}-based diagnosis of diabetes mellitus in Koreans

C.-H. Kim[1], H.-K. Kim[2], S.J. Bae[2], J.Y. Park[3], K.-U. Lee[3];
[1]Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Kyeonggi-do, [2]Health Promotion Center, Asan Medical Center, Seoul, [3]Internal Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea.

Background and aims: Recently, the International Expert Committee recommended that hemoglobin A1c (HbA1c) ≥ 6.5% to be included as a diagnostic criterion for diabetes mellitus. However, the degree of diagnostic agreement with the fasting glucose-based criteria may be different across ethnic groups and populations. The aim of this study was to examine the difference between using fasting plasma glucose (FPG) and HbA1c criteria in screening for diabetes in Korean asymptomatic health check-up recipients.
Materials and methods: We retrospectively analyzed clinical and laboratory data of 37,754 Korean adults (age 20-89 years, 41% women) which were recorded during regular health check-ups. After excluding subjects with previously diagnosed diabetes mellitus (n = 1,812) and significant anemia or hemoglobinopathies (n = 318), 35,624 subjects (21,201 men and 14,423 women) were categorized by FPG (126 mg/dL) and HbA1c (6.5%) cutoff values.
Results: Among the 35,624 subjects without known diabetes, 1143 (3.2%) patients were newly diagnosed as having diabetes using FPG criteria and 1019 (2.9%) patients by HbA1c criteria (Table 1). Thus, using HbA1c alone could detect slightly less (-9%) diabetic patients compared with using FPG alone. By combining both FPG and HbA1c criteria, 1493 (4.2%) patients previously unknown to have diabetes could be newly diagnosed. Therefore, about 30% more diabetic patients could be detected by including new HbA1c criteria in addition to FPG criteria. Among the 1493 newly diagnosed diabetic subjects, 473 (31.6%) met FPG criteria only (DM-FPG group), 350 (23.5%) met HbA1c criteria only (DM-A1c group), and 668 (44.9%) were diagnosed as diabetes by both criteria. When we compared the DM-FPG and DM-A1c group, DM-A1c group were significantly older (55.1 ± 9.4 vs. 53.4 ± 9.2 years, $P = 0.032$), and had lower blood hemoglobin concentration (14.6 ± 1.5 vs. 15.2 ± 1.3 mg/dL, $P < 0.001$). In contrast, DM-IFG group had higher systolic (123 ± 15 vs. 119 ± 13 mmHg, $P = 0.006$) and diastolic (78 ± 9 vs. 74 ± 9 mmHg, $P < 0.001$) blood pressure, fasting serum insulin level (11.5 ± 8.7 vs. 8.8 ± 5.5 mIU/L, $P < 0.001$) and HOMA-IR (3.81 ± 2.95 vs. 2.47 ± 1.57, $P < 0.001$).
Conclusion: There was significant discordance in diagnosing diabetes mellitus between the FPG- and HbA1c-based criteria. Our results support the notion that fasting glucose criteria may be better in detecting patients with hepatic insulin resistance, while HbA1c criteria may be more useful in patients with predominant impairment of postprandial glucose metabolism. Further studies are needed to know which criterion is better in predicting the risk of long-term vascular complications of diabetes.

Table 1. Prevalences (%) of newly diagnosed diabetes mellitus in health check-up recipients according to age groups by fasting plasma glucose (FPG) and HbA1c criteria

	20-29	30-39	40-49	50-59	60-69	70-89	Total
FPG	0.4	1.5	2.8	3.9	4.7	7.7	3.2
HbA1c	0.3	1.4	2.3	3.5	4.8	6.4	2.9
Combined	0.5	1.8	3.4	5.1	6.9	10.7	4.2

OP 34 Inflammation in insulin resistance

199

Effect of IL-1beta and TNFalpha inhibition on insulin secretion and metabolic control of type 2 diabetes patients with overweight or obesity

M. González-Ortiz[1,2], M.G. Ramos-Zavala[1], E. Martínez-Abundis[1,2], J.A. Robles-Cervantes[1], R. González-López[1], N.J. Santiago-Hernández[1]; [1]Medical Research Unit in Clinical Epidemiology, Mexican Institute of Social Security, [2]Physiology Department, University of Guadalajara, Jalisco, Mexico.

Background and aims: To compare the effect of IL-1β and TNFα inhibition on insulin secretion and metabolic control of type 2 diabetes patients with overweight or obesity.
Materials and methods: A randomized, double-blind, placebo-controlled clinical trial was carried out in 40 type 2 diabetes patients, aged between 40 to 60 years, BMI between 25 to 34.9 Kg/m², glucose between 126 to 200 mg/dl, A1C >7%, without pharmacological treatment. At beginning and at end of the study, BMI, blood pressures, a metabolic profile (fasting glucose, A1C and lipids), IL-1β and TNFα concentrations were measured, as well as, insulin secretion assessment using the hyperglycemic - hyperinsulinemic clamp technique. The patients were randomly assigned to receive diacerein (50 mg twice/day), an inhibitor of IL-1β and TNFα, or placebo for a period of 60 days. Statistical analyses were calculated with Mann-Whitney U and Wilcoxon tests. The study protocol was reviewed and approved by the hospital-based Ethic Committee and written informed consent was obtained from all volunteers.
Results: In both groups decreased the BMI (30.9 ± 2.5 vs. 29.8 ± 2.5 kg/m², p = 0.002 and 30.6 ± 2.6 vs. 29.8 ± 2.8 kg/m², p = 0.001; respectively placebo and diacerein groups) in the same magnitude, p = 0.756. Diastolic blood pressure (77 ± 8 vs. 75 ± 6 mmHg, p = 0.040), fasting glucose (145 ± 28 vs. 124 ± 19 mg/dl, p = 0.001), A1C (8.3 ± 1.0 vs. 7.0 ± 0.8%, p <0.001), IL-1β (26.4 ± 6.6 vs. 17.9 ± 2.7 pg/ml, p=0.005), and TNFα concentrations (18.2 ± 3.9 vs. 13.8 ± 2.7 pg/ml, p=0.003) decreased significantly with diacerin administration, as well as increasing in first (17.0 ± 10.6 vs. 21.8 ± 12.7 μU/ml, p = 0.002), late (36.6 ± 18.6 vs. 46.9 ± 22.5 μU/ml, p = 0.002) and total (29.9 ± 15.4 vs. 36.1 ± 16.6, p = 0.002) phases of insulin secretion were observed.
Conclusion: Inhibition of IL-1β and TNFα by means of diacerein administration improved insulin secretion and the metabolic control of type 2 diabetes patients with overweight or obesity.

200

CCR5 promotes adipose tissue inflammation and insulin resistance in obesity

T. Ota, H. Kitade, K. Sawamoto, H. Inoue, S. Kaneko;
Frontier Science Organization, Kanazawa University, Japan.

Background and aims: Adipose tissue macrophages (ATMs) play a critical role in obesity-induced inflammation and insulin resistance. Monocyte chemoattractant protein-1 (MCP-1) and its receptor CCR2 are important for ATM recruitment and the development of insulin resistance. However, deficiency of CCR2 or MCP-1 does not normalize obesity-induced ATM recruitment and insulin resistance. Therefore, other chemokine systems could also play a role in these processes. Recent reports have also shown that CCR5, a different CC chemokine receptor, and its ligands are upregulated in adipose tissue of human obesity. However, it is not known if CCR5 is involved in ATM recruitment and insulin resistance. Here, we investigated the role of CCR5 in obesity-induced adipose tissue inflammation and systemic insulin resistance by high fat (HF) feeding or leptin deficiency.
Materials and methods: We analyzed gene expression levels of several chemokines and their receptors in white adipose tissue (WAT) of genetically (ob/ob) and HF diet-induced obese (DIO) mice. To determine whether CCR5 is required for obesity-induced ATM recruitment and insulin resistance, we examined metabolic phenotype of CCR5-/- mice. In addition, we performed bone marrow transplantation (BMT) of CCR5-/- mice or wild type (WT) C57Bl/6J mice donor cells into irradiated WT recipient mice to generate myeloid cell specific chimeric mice.
Results: Expression of mRNA for CCR5 and its all ligands was markedly increased in WAT in both DIO mice (CCR5,11.1-; MIP-1α, 5.2-; MIP-1β, 5.2-; RANTES, 4.0-; MCP-2, 2.1-fold; all p<0.05 vs WT) and ob/ob mice (CCR5, 5.3-; MIP-1α,17.5-; MIP-1β, 19.9-; RANTES,4.9-; MCP-2,15.9-fold; all p<0.05 vs WT) at 15 weeks of age. Interestingly, upregulation of CCR5 and its ligands preceded ATM recruitment in DIO mice, and their expression levels were higher than MCP-1/CCR2 in ob/ob mice. CCR5-/- mice fed normal chow showed slightly better glucose tolerance. On a HF diet, CCR5-/- mice had decreased macrophage infiltration and crown-like structure formation in adipose tissue compared with WT mice at 20 weeks, even though weight and adipocyte size (191.5±9.3 vs 186.3±6.4 μm p=0.4) were similar. HF diet-induced insulin resistance and glucose intolerance were also significantly improved in CCR5-/- mice. These findings were associated with decreased inflammatory cytokine expression (TNFα and iNOS), reduction of endoplasmic reticulum stress evaluated by XBP-1 splicing, attenuation of MAPK (p38-MAPK, JNK) and NF-κB activation in adipose tissue, and improvement of hepatic steatosis. We next introduced CCR5 deficiency into ob/ob mice to generate double-knockout (DKO) mice. DKO mice were strikingly resistant to the development of both insulin resistance and fatty liver. DKO mice also had decreased ATM recruitment compared to ob/ob littermates. Importantly, mRNA expression for CCR5 and its ligands in adipose tissue was higher in stromal vascular fraction than adipocyte fraction from DIO mice at 15 weeks. Furthermore, BMT study revealed that chimeric mice lacking CCR5 in myeloid cells were protected from HF diet-induced hyperinsulinemia (CCR5-/-BMT 2.6±0.3 vs WT-BMT 5.1±1.1 ng/ml, p<0.05) and glucose intolerance.
Conclusion: Expression of CCR5 and its ligands is markedly increased in WAT of obese mouse models. Deficiency of CCR5 prevents insulin resistance induced by HF feeding or leptin deficiency. Therefore, CCR5 plays a crucial role in ATM recruitment and subsequent development of insulin resistance independently of MCP-1/CCR2.

Heat shock protein 60 stimulates the secretion of pro-inflammatory adipokines from human adipocytes and induces insulin resistance in human skeletal muscle cells

H. Sell[1], T. Märker[2], S. Famulla[1], A. Glöde[2], P. Zilleßen[2], C. Habich[2], J. Eckel[1];
[1]Institute for Clinical Biochemistry and Pathobiochemistry, [2]Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Adipose tissue is an endocrine active organ producing a variety of bioactive proteins. In the obese state expanded adipose tissue releases increased amounts of pro-inflammatory adipokines which mediate adipose tissue inflammation. It is well-known that obesity is a strong risk factor for the development of insulin resistance and a component of the metabolic syndrome which involves the crosstalk between adipose tissue and skeletal muscle. Adipokines released from enlarged fat cells are important mediators of this crosstalk by autocrine/paracrine and endocrine effects. The autologous stress protein heat shock protein 60 (Hsp60) is released from adipocytes and increased in serum of diabetic patients. This study is aimed to analyze the effects of Hsp60 on the release of adipokines from human adipocytes and to assess if Hsp60 affects insulin sensitivity of human skeletal muscle cells.
Materials and methods: Preadipocytes were isolated from subcutaneous adipose tissue of lean or overweight healthy women and differentiated *in vitro*. The release of pro-inflammatory adipokines after LPS and Hsp60 treatment was measured by a multiplex beads analyses. The specificity of Hsp60-binding to human adipocyte receptor structures was analyzed. *In vitro* differentiated skeletal muscle cells were incubated with Hsp60 concentrations ranging from 1 to 20 μg/ml. Insulin signaling and the induction of pro-inflammatory and stress pathways were analyzed by Western blotting.
Results: Unstimulated human preadipocytes and adipocytes secrete measurable amounts of TNFα, IL-6, IL-8, MCP-1 and RANTES. Hsp60 treatment leads to significantly increased secretion of TNFα (up to 168-fold), IL-8 (up to 7-fold) and RANTES (up to 9-fold) from preadipocytes as compared to untreated preadipocytes. As for mature adipocytes, Hsp60 stimulated the secretion of TNFα (up to 21-fold), IL-6 (up to 32-fold), IL-8 (up to 3-fold), MCP-1 (up to 6-fold) and RANTES (up to 8-fold) compared to unstimulated adipocytes. The specificity of Hsp60-Binding on human adipocytes could be demonstrated by binding assays. Binding of labeled Hsp60 could be inhibited by up to 69 % using unlabeled Hsp60, whereas ovalbumin was without effect. As human adipocytes express and release Hsp60, we tested the effect of this adipokine on skeletal muscle cells. Hsp60 activates pro-inflammatory and stress signaling in skeletal muscle cells in a dose-dependent way. Hsp60 significantly increases the phosphorylation of NF-κB, JNK and ERK1/2 up to 2-

to 3-fold over the control level. Hsp60 also induces insulin resistance on the level of insulin-stimulated Akt and GSK3 phosphorylation in a dose-dependent manner with significant inhibition being observed at concentrations from 5 to 20 μg/ml of Hsp60 which reflects pathophysiological concentrations.
Conclusion: We demonstrate for the first time that treatment of human preadipocytes and adipocytes with Hsp60 results in increased release of various pro-inflammatory adipokines in a dose- and differentiation-dependent way. In skeletal muscle cells Hsp60 activates pro-inflammatory signaling pathways and leads to impaired insulin signaling. Therefore, Hsp60 might be a factor contributing to adipose tissue inflammation and obesity-associated insulin resistance.

Communication between insulin-resistant skeletal muscle and beta cells
K. Bouzakri[1], P. Ribaux[1], T. Berney[2], M.Y. Donath[3], P.A. Halban[1];
[1]Department of Genetic Medicine and Development, CMU, Geneva, [2]Cell Isolation and Transplantation Center, Division of Surgical Research, Department of Surgery, University Hospital, Geneva, [3]Division of Endocrinology and Diabetes, Department of Internal Medicine, University Hospital, Zurich, Switzerland.

Background and aims: Obesity and type 2 diabetes mellitus are characterized by an overlapping phenotype of insulin resistance with a relative deficiency in insulin secretion underlying hyperglycemia in type 2 diabetes. Systemic inflammation is another common feature, raising the hypothesis that elevated cytokine levels may contribute to peripheral insulin resistance and decreased beta cell functional mass. In healthy humans, TNF-α infusion induces skeletal muscle insulin resistance. We now explore the potential communication between insulin-resistant skeletal muscle and beta-cells.
Materials and methods: Human skeletal muscle cells were cultured for up to 24h with or without (control) 20 ng/ml TNF-α to induce insulin resistance. mRNA expression for cytokines was analysed after 8h by hybridising cDNA to low-density oligo-nucleotide arrays. Conditioned media (test: TNF-α-CM; control: C-CM) were collected and candidate cytokines were measured by antibody array. Human and rat primary beta-cells were used to explore the impact of exposure to conditioned media for 24h on apoptosis (TUNEL assay), proliferation (BrdU incorporation), short-term insulin secretion, and key signalling protein phosphorylation and expression. Data are mean+/-SE.
Results: Muscle cells (n=4) treated for 8h showed an increase in expression of 19 cytokine and chemokine genes (confirmed and quantified by RT-qPCR) with increased amounts of 13 cytokines after 24h in TNF-α-CM vs. C-CM. Both TNF-α-CM and TNF-α alone added to C-CM at the start of the beta-cell culture decreased glucose-stimulated insulin secretion to a similar extent. However, only TNF-α-CM also increased human and rat beta-cell apoptosis by 6.22+/- 2.1 and 6.14+/- 0.9 -fold respectively ($p< 0.05$) and decreased proliferation of rat beta-cells (1.08 +/- 0.15 vs. 8.2 +/- 1.7 % BrdU positive cells, TNF-α-CM vs. C-CM, $p<0.01$). In rat beta-cells, 1h of glucose stimulation (16.7 mM) induced phosphorylation of proteins from the insulin signalling pathway including Akt, AS160, other Akt substrates, and ERK, an effect prevented by prior culture for 24h with TNF-α-CM. Both TNF-α-CM and TNF-α added to C-CM decreased IRS-2 protein by approx. 60% but only TNF-α-CM also decreased IRS-2 mRNA by 42 +/- 5 % vs. C-CM ($p<0.05$). Interestingly, both CM and TNF-α-CM increased IRS-1 protein and mRNA expression. In order to identify which mechanism was involved in the specific effects of TNF-α-CM and potentially attributable to insulin-resistant muscle cytokines, rat beta-cells were pre-treated with GLP-1, IL1-Ra or IL6 blocker (AF-227-NA and Sant 7). Both GLP-1 and IL1-Ra partially protected against the TNF-α-CM evoked increased in apoptosis but not the decreased proliferation.
Conclusion: Taken together these results show that induction of insulin-resistance in human skeletal muscle by TNF-α leads to secretion of myokines which impact negatively on beta-cell proliferation and survival. The identification of these myokines and their molecular targets on beta-cells opens the possibility for new therapeutic strategies for preservation of functional beta-cell mass in type 2 diabetes.

IL-6 stimulated TLR-4 gene expression via mTOR and STAT3 in human skeletal muscles myotube and human skeletal muscle of IGT subject
S.-E. Choi[1], T.H. Kim[1], E.S. Ha[1], S.Y. An[1], Y.J. Jung[1], E.K. Kim[1], M.S. Lee[1], S.J. Han[1], H.J. Kim[1], D.J. Kim[1], Y. Kang[2], K.-W. Lee[1];
[1]Endocrinology and Metabolism, [2]Institute for Medical Science, Ajou University School of Medicine, Suwon, Republic of Korea.

Insulin resistance is associated with chronic inflammation, and many inflammatory cytokines and signaling pathways are involved. In this study we investigated the cytokines and mechanisms involved in the induction of insulin resistance in human skeletal muscle. We recruited 10 IGT subjects and 10 control subjects. Whole-body insulin-mediated glucose uptake was determined using a euglycemic hyperinsulinemic clamp test. Muscle biopsies were obtained from the vastus lateralis muscle. We determined levels of inflammatory cytokine, TLR gene expression, and insulin signaling using immunoblotting. We examined the mechanisms underlying TLR-4 gene expression using a human myotube culture system. Fasting blood glucose was significantly higher in IGT subjects than the controls. HbA1c showed a tendency to be higher in IGT subjects ($p=0.059$). Although there was no difference in HOMA beta cell function between the two groups, glucose utilization rates were significantly lower in the IGT group. Levels of IL-6, TNF-α, and TLR-4 was significantly increased in the IGT group, but TLR-2 was not. We studied which inflammatory cytokines induce TLR-4 gene expression using IL-6, TNF-α, free fatty acid, and high glucose. TLR-4 gene expression increased significantly in human skeletal muscle myoblasts treated with IL-6. To determine the main signaling pathway for IL-6-induced TLR-4 gene expression, we examined several signaling factors associated with IL-6 signaling pathways. We found that the active forms of signal transducer and activator of transcription3 (STAT3) was increased in the IGT group as compared with controls (mTOR: 183.22 ± 13.01 vs. 100 ± 12.63, $p < 0.05$; STAT3: 170.3949 ± 18.11 vs. 14.64, $p < 0.05$). Stattic (STAT3 inhibitor) markedly inhibited TLR-4 gene expression. We suggest IL-6 induction of TLR-4 gene expression via STAT3 is one of the main mechanisms underlying insulin resistance in human skeletal muscle.

Toll-like receptor 2 knockout mice present iNOS-dependent insulin resistance
A.M. Caricilli[1], P.K. Picardi[1], L.L.F. de Abreu[1], M. Ueno[1], P.O. Prada[1], S.M. Hirabara[2], R. Curi[3], J. Carvalheira[1], L.A. Velloso[1], M.J.A. Saad[1];
[1]UNICAMP, Campinas, [2]UNICSUL, São Paulo, [3]USP, São Paulo, Brazil.

Background and aims: There are evidences that the activation of JNK, IKK and iNOS pathways are associated with the reduction of the insulin sensitivity, but only recently it has been shown that those pathways can be integrated in the insulin resistance by membrane receptors, such as the Toll-like Receptors (TLRs). Studies in our laboratory show that mice with an inactivating mutation of TLR4 are protected from diet-induced obesity and activation of IKKβ and JNK. It is possible that other TLRs participate in this phenomenon. TLR2 is a good candidate, because it is activated by saturated fatty acids. However, no study has characterized the role of TLR2 in the insulin resistance of animal models. Therefore, the goal of the present study is to investigate the role of TLR2 on insulin resistance of mice.
Materials and methods: We investigated weight gain, insulin sensitivity and signaling in liver, muscle and white adipose tissue in TLR2 knockout (KO) mice and their controls, both fed with a standard chow. The glucose utilization was studied through euglicemic-hyperinsulinemic clamp, the protein signaling through Western Blotting, serum insulin, IL-6 and TNF-α through ELISA, oxygen consumption through an indirect open circuit calorimeter and glucose uptake by the soleus muscle was determined in vitro using 2-deoxy-D-[2,6-3H] glucose. In order to inhibit the expression of JNK and iNOS, we used SP600125 (30mg/kg body weight) and l-N6-(l-iminoethyl) lysine (l-NIL; 80 mg/kg body weight). All procedures were approved by the ethics committee at the Sytate University of Campinas.
Results: The animals were similar in concern to the weight gain, however TLR2 KO mice had a decreased oxygen consumption and a decreased UCP1 expression comparing with their controls. Moreover, TLR2 KO mice presented decreased glucose tolerance and decreased insulin sensitivity. The insulin signaling was also alterated in these animals, because the activation of the insulin receptor and of AKT was reduced. IKK activation was reduced in TLR2 KO mice, which was accompanied by the decreased serum concentra-

tion of IL-6 and TNF-α comparing with the controls, while the phosphorylation of JNK was increased in muscle and liver, suggesting that other proteins might be involved in the modulation of the insulin signaling, leading to an increased activation of JNK. In order to elucidate this question, we studied proteins associated with the endoplasmic reticulum (ER) stress, since they activate JNK, and observed an increased phosphorylation of PERK and an increased expression of IRE-1α, which are associated with the ER stress. However, when inhibiting the expression of JNK and iNOS, we observed that only the inhibition of iNOS was able to improve the insulin sensitivy, suggesting that the insulin resistance in these animals is iNOS-dependent.
Conclusion: Although we have found many activated mechanisms that have the potential of inducing insulin resistance in TLR2 KO mice, only one was capable of reversing this state - the iNOS pathway. Therefore, TLR2 KO mice present iNOS-dependent insulin resistance.

Fork-head box transcription factor, FoxO1 inhibits glucose-regulated insulin gene expression in pancreatic beta cells by direct binding to the promoter region
G. Meur[1], Q. Qian[2], G. Da Silva Xavier[1], T. Tsuboi[2], C. McKinnon[2], L.M. Fletcher[2], J.M. Tavaré[2], G.A. Rutter[1];
[1]Division of Diabetes, Endocrinology and Metabolism, Imperial College, London, [2]Department of Biochemistry, University of Bristol, United Kingdom.

Background and aims: Glucose and insulin stimulate preproinsulin (PPI) gene expression in pancreatic beta cells through mechanisms which are only partly defined. Pancreatic duodenum homeobox-1 (Pdx1) is a major transactivator of PPI whose action is antagonised by the fork-head box member protein, FoxO1. The effect of FoxO1 is thought to be largely due to inhibition of Pdx1 expression. However, we have also noted that a potential binding site also exists in the 5' flanking region of the rodent, and intron 2 of the human, PPI genes. Here we explore whether FoxO1 directly binds to this site to regulate insulin gene expression and examine the intracellular signalling pathways involved.
Materials and methods: Adenoviruses expressing wild type and a constitutively active (S256A) FoxO1-GFP and wild type Pdx1 were generated by standard techniques. Silencing of FoxO1 was achieved after 48 h of transfection of SiRNAs (10nM, Smart Pool) with Lipofectamine RNAiMAX in MIN6 beta cell lines. Chromatin immunoprecipitation was carried out after 24 h of CA-FoxO1 viral transduction, using a monoclonal anti-GFP antibody and CHIP grade protein G agarose. Real-time FoxO1 translocation was studied using a Nipkow spinning disc confocal microscope. The mRNA level was measured by qRT PCR using an ABI Fast Real-time PCR system normalised to endogenous cyclopholin. Insulin promoter-luciferase assays were carried out using a Stop and Glo, dual-luciferase kit. Statistical analyses of significance were done by Student's *t* test or ANOVA.
Results: Culturing of MIN6 beta cells at low (3mM versus 30mM) glucose led to a 2-3 fold decrease in PPI and Pdx1 mRNA levels. Constitutively active FoxO1-GFP over-expression led to a decrease in insulin and Pdx1 gene expression even at high glucose while silencing (~75%) of FoxO1 abolished the effects of low glucose. The effects of FoxO1 over-expression on PPI mRNA levels were still observed in the presence of over-expressed Pdx1 though both were present in the nucleus, and consistent with the direct action of FoxO1 on the insulin gene promoter. Chromatin immunoprecipitation using an anti-GFP antibody revealed direct binding of FoxO1 to a region located -768 to -141bp upstream of the transcriptional start site. FoxO1 over-expression inhibited the activity of an insulin promoter-reporter (luciferase) construct bearing this region and the latter inhibition was retained after co-expression of Pdx1, but lost in a truncated construct lacking the putative FoxO1 binding site. Confocal imaging revealed that wild type FoxO1-GFP translocated from the nucleus after 30-60 min of exposure to high glucose and this shift was blocked by a pharmacological inhibitor of phosphatidyl inositol 3' kinase (PI 3-kinase, LY294002) but not by inhibitors of glycogen synthase kinase 3 (GSK3 beta, SB216763 and SB415286).
Conclusion: We show here that FoxO1, which is regulated through a PI 3-kinase dependent signalling pathway, has a direct binding site on rodent insulin gene promoter. This newly identified mechanism may contribute to the regulation of endogenous Insulin and Pdx1 gene complimenting an effect on Pdx1 promoter described previously. Further dissection of this pathway may provide new therapeutic approaches to regulating the insulin gene in type 2 diabetes.

Carbohydrate-Responsive Element-Binding Protein (ChREBP) activity is regulated by Ca^{2+} ions in pancreatic beta cells via soluble resistant-related calcium binding protein (Sorcin)
N.A. Noordeen, G. Meur, P. Patel, G.A. Rutter, I. Leclerc;
Dept. Cell Biology / Div. Diabetes, Endocrinology & Metabolism, Imperial College, London, United Kingdom.

Background and aims: We have recently shown that ChREBP is an important mediator of pancreatic beta cell glucolipotoxicity. ChREBP activation by

high glucose increases the expression of the lipogenic genes liver-type pyruvate kinase (L-PK) and fatty acid synthase (FAS) and inhibits the expression of ARNT/HIF1-β . We have also shown previously that Ca^{2+} influx is necessary for ChREBP activation in these cells. However, the precise molecular mechanism(s) through which ChREBP activity may be regulated by Ca^{2+} is unknown.
Materials and methods: A yeast two-hybrid screen was performed using ChREBP as a bait and the Matchmaker Gal4 Two-Hybrid System 3 (Clontech) with an in-house MIN6 pancreatic β cell library. Mammalian cell transfection was carried out using Lipofectamine 2000, and cells were imaged using a Zeiss Axiovert 200M microscope fitted with a PlanApo x63 oil-immersion objective. Confocalilty was achieved using a Nipkow spinning disc under the control of Volocity™ 4.0 (Improvision) software. An EGFP-ChREBP chimaera was generated by in-frame fusion of the corresponding cDNAs. Sorcin-specific siRNAs were purchased from Dharmacon. Chromatin immunoprecipitation was carried out using an in-house rabbit polyclonal anti-ChREBP antibody.
Results: Sorcin, a penta EF hand Ca^{2+} binding protein, was identified as a ChREBP interacting partner by yeast two-hybrid analysis. We confirmed that sorcin and ChREBP interacted in INS-1(832/13) and MIN6 β cells by co-immunoprecipitation and that they also co-localised in the cytosol in a punctiform pattern in cells maintained in 3 mM glucose, as revealed by confocal microscopy. However, the extent of ChREBP and sorcin colocalisation was markedly reduced when cells were maintained at elevated (30 mM) glucose concentrations, where ChREBP staining became apparent in the nucleus. Moreover, ChREBP binding to the L-PK promoter, assessed by chromatin immunoprecipitation, was increased at low glucose concentrations following sorcin inactivation by RNA interference. As the apparent physical interaction of sorcin with ChREBP implied that ChREBP may be regulated by intracellular Ca^{2+}, we tested the ability of ChREBP to respond to elevated intracellular levels of these ions. Using live cell imaging of a GFP-tagged ChREBP construct, we found that ChREBP translocated into the nucleus within 5 - 7 min. of cell depolarization with 50 mM K^+ and activated Ca^{2+} influx. Finally, demonstrating the likely importance of sorcin in retaining ChREBP in the cytosol, sorcin silencing significantly inhibited insulin secretion from MIN6 β cells.
Conclusion: These results demonstrate that sorcin is a physiologically relevant molecular binding partner from ChREBP, and define a role for sorcin in β cell function and insulin secretion. We propose a model wherein, at low glucose concentrations, sorcin sequesters ChREBP in the cytosol. Elevated glucose concentrations, which trigger Ca^{2+} influx, lead to conformational changes in sorcin which release ChREBP and allow it to translocate into the nucleus to regulate the transcription of genes involved in lipid synthesis. The up-regulation of these target genes may then contribute to gluco-lipotoxicity, and hence diminished beta cell function and survival, in the context of type 2 diabetes.

Beta cell specific c-Kit receptor over-expression improves beta cell growth and function
R. Wang[1], S.-P. Yee[2], J. Li[1];
[1]Physiology & Pahrmacology, Children's Health Research Institute, the University of Western Ontario, London, Canada, [2]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, USA.

Background and aims: One of the major defects in diabetes is the loss of insulin producing cells in the pancreas. The reasons for beta-cell loss are not well understood. We previously focused on determining factors responsible for the maintenance of beta-cell mass and function and have demonstrated that the c-Kit receptor and its ligand, stem cell factor (SCF), are important for both rodent and human pancreatic islets. These results show that c-Kit is not only a marker of beta-cell precursors but is also critical for beta-cell proliferation, maturation, function and survival *in vitro*. Study on the *c-Kit*$^{Wv/+}$ mice further showed that the mutant male mice displayed early onset of diabetes. However, a better understanding of the underlying mechanisms is necessary prior to the development of novel physiologically relevant cell-based approaches to treat and manage diabetes. The aim of the present study is to examine whether a beta-cell specific c-Kit overexpression would have physiological and functional implications in beta-cell development and function.
Materials and methods: A beta-cells specific over-expression c-Kit [RIP-c-Kit(h)] transgenic mouse model in *C57BL/6J* background was generated followed by the characterization of beta-cell proliferation and function.
Results: We found that the beta-cell specific c-Kit transgenic mice display relatively large body mass and normal fasting blood glucose level compared to the control littermates. However, a significant improved glucose tolerance in the beta-cell c-Kit transgenic mice at both 4 and 8 weeks of age was observed ($p<0.05$). Morphometric analysis revealed a significant increase in the islet number and size ($p<0.01$) at 4 weeks of age. Increase beta-cell mass in beta-cell c-Kit transgenic mice along with an increase in beta-cell proliferation, Pdx-1 and Nkx6.1 expression compared with controls ($p<0.05$).
Conclusion: Our results demonstrate that c-Kit receptor tyrosine kinase is involved in the regulation of glucose metabolism and contributes to the maintenance of beta-cell function.

Mitochondria distinguish between fast and slow cytosolic Ca^{2+} oscillations in pancreatic beta cells
A.I. Tarasov[1], M.A. Ravier[1,2], E.A. Bellomo[1], G.A. Rutter[1];
[1]Department of Medicine, Imperial College London, United Kingdom, [2]INSERM, Montpellier, France.

Background and aims: The normal pulsatility of insulin secretion from pancreatic beta cells, critical for maintenance of glucose homeostasis, is lost in type 2 diabetic patients. Mitochondrial Ca^{2+} uptake has been suggested to be involved in the control of oxidative metabolism and ATP generation which, via the closure of ATP-sensitive K^+ channels, may underlie fluctuations in the electrical activity of the beta cell plasma membrane. Whether Ca^{2+} influx into mitochondria can occur rapidly enough to contribute to the polarisation of the plasma membrane during glucose-induced bursts of electrical activity, or to slower oscillations in plasma membrane potential (V_m), is unknown. Here, we have combined optical imaging of targeted probes and patch clamp electrophysiology to monitor cytoplasmic $[Ca^{2+}]$ ($[Ca^{2+}]_c$), intramitochondrial $[Ca^{2+}]$ ($[Ca^{2+}]_m$), and V_m simultaneously in single living beta cells. The relationship between these parameters was studied in response to glucose or other stimuli.
Materials and methods: Mouse beta cells were infected with an adenovirus encoding the ratiometric GFP-based mitochondrial Ca^{2+} sensor, pericam. V_m was manipulated using the perforated-patch patch-clamp technique. The dynamics of Ca^{2+} changes in the cytosol (Fura-Red) and mitochondria (pericam) were imaged simultaneously using appropriate excitation wavelengths (490 and 410 nm respectively) and emission filters.
Results: Glucose (17 vs 3 mM) induced slow (2-5 min period) oscillations in $[Ca^{2+}]_c$. The onset of each oscillation was tracked by changes in $[Ca^{2+}]_m$, with the changes delayed by ~10s. Each glucose-induced increase of $[Ca^{2+}]_c$ was preceded by depolarization of the plasma membrane. The imposition of depolarizations by extracellular K^+ was able to mimic the glucose-induced oscillations of Ca^{2+} in both compartments, indicating that mitochondrial Ca^{2+} uptake occurred as a result of the $[Ca^{2+}]_c$ increase. Likewise, acetylcholine-mediated Ca^{2+} mobilization from intracellular stores prompted increases in $[Ca^{2+}]_m$ and these were also delayed compared to the $[Ca^{2+}]_c$ increases. For a given $[Ca^{2+}]_c$ rise, peak $[Ca^{2+}]_m$ values were larger after cell membrane depolarization than after Ca^{2+} mobilization. To explore whether $[Ca^{2+}]_c$ changes elicited by rapid membrane depolarizations could be sensed by mitochondria we next imposed trains of action potentials, mimicking those provoked by glucose, by voltage clamping the cell membrane. Such trains (23 pulses to 0 mV in 6 s imposed in 15 s intervals) led to increases in $[Ca^{2+}]_c$, which were maximal after the first burst, and partially recovered between bursts. By contrast, $[Ca^{2+}]_m$ did not increase detectably until the third burst in this protocol, and did not increase at all when the interburst interval was increased to >30 s.
Conclusion: We show that Ca^{2+} accumulation by beta cell mitochondria is dependent upon the duration and frequency of $[Ca^{2+}]_c$ pulses. These results suggest that: (a) the filtering out by mitochondria of $[Ca^{2+}]_c$ oscillations with sub-threshold frequency may contribute to the steep dependency of insulin secretion upon glucose concentration; (b) mitochondrial Ca^{2+} uptake and release are not a prerequisite for plasma membrane bursting electrical activity; (c) deranged uptake of Ca^{2+} by mitochondria may contribute to defective insulin secretion in some forms of type 2 diabetes.

Impaired pancreatic beta cell Ca^{2+} dynamics and function in premature ageing

L. Li[1], A. Trifunovic[2,3], M. Köhler[1], J. Petrovic-Berglund[1,4], N.-G. Larsson[2,5], P.-O. Berggren[1];
[1]The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, [2]Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden, [3]CECAD Cologne - Excellent in Aging Research at the Institute for Genetics, University of Cologne, Germany, [4]Department of Cell Biology, Duke University Medical Center, Durham, USA, [5]Max Planck Institute for Biology of Ageing, Cologne, Germany.

Background and aims: People over age 65 have a significantly increased risk for type 2 diabetes. In ageing humans, only those whose beta-cells fail to compensate for insulin resistance develop diabetes. However, the ageing of beta-cells is poorly understood. Here we, for the first time, demonstrates a clear coupling between ageing and impaired pancreatic beta-cell function and thereby glucose homeostasis in mice with premature ageing induced by accumulation of mitochondrial DNA (mtDNA) mutations.
Materials and methods: We used homozygous knock-in mice expressing a proofreading-deficient form of the catalytic subunit of mtDNA polymerase γαμμα. This mutant polymerase γαμμα induces error-prone mtDNA synthesis, which, in turn, leads to accumulation of somatic mtDNA mutations with increasing age and a reduced lifespan and premature onset of ageing-related phenotypes. We performed glucose and insulin tolerance tests in animals. Cytochrome c oxidase and succinate dehydrogenase activities were measured by enzyme histochemical double staining of cryostat sections from pancreas. In isolated islets, measurements of glucose-stimulated changes in insulin release, mitochondrial membrane potential and cytoplasmic free Ca2+ concentration ([Ca2+]i) were performed.
Results: Compared to wild-type littermate control mice, the mtDNA mutator mice develop impaired glucose tolerance ($p<0.05$) due to progressive mitochondrial respiratory chain dysfunction in pancreatic islets and subsequent deficiency in glucose-stimulated insulin secretion ($p<0.01$). Both δελτα rhodamine 123 fluorescence, a probe to measure mitochondrial membrane potential, and δελτα peak [Ca2+]i values were decreased in islets obtained from mtDNA mutator mice after stimulation by 11 mM glucose ($p<0.001$ and $p<0.01$). We further demonstrate that the progressive decline in pancreatic beta-cell function in mice with premature-ageing phenotypes is associated with a slower frequency ($p<0.05$) and decreased amplitude ($p<0.001$) of glucose-stimulated oscillations in [Ca2+]i. The latter findings are likely to be accounted for by down-regulated PLC/InsP3-mediated Ca2+ mobilization from intracellular stores and decreased beta-cell Ca2+ influx over the plasma membrane.
Conclusion: This study demonstrates that an age-related deterioration in [Ca2+]i signaling serves as a link between impaired beta-cell function and premature ageing in mtDNA mutator mice. It also suggests that enhancement in beta-cell Ca2+ signaling can be a potential target for the development of novel pharmacological regimens in the treatment of diabetes in the ageing population.

Loss of anti-apoptotic Bcl-x_L or Bcl-2 enhances beta cell glucose signalling

D.S. Luciani, S.B. Widenmaier, F. Taghizadeh, X. Hu, J.D. Johnson;
Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

Background and aims: In many cell types, including pancreatic beta-cells, Bcl-2 and Bcl-x_L have been demonstrated to preserve mitochondrial integrity and suppress apoptosis under a variety of cellular stress conditions. Whether these important pro-survival proteins also regulate beta-cell physiology in vivo or in vitro under normal conditions is not known. In this study we used a combination of genetic and pharmacological loss-of function approaches to test the hypothesis that Bcl-2 and Bcl-x_L impact beta-cell energy metabolism, calcium homeostasis and insulin secretion.
Materials and methods: Beta-cell function and glucose homeostasis were studied in vivo and following conditional deletion of Bcl-x in adult beta-cells by tamoxifen-injection of Bcl-$x^{flox/flox}$;Pdx1-CreER (Bcl-x KO) and littermate Bcl-$x^{flox/flox}$ (Bcl-x WT) control mice. Glucose signalling was assessed in islets and dispersed beta-cells from Bcl-2 knockout, heterozygous and wild-type littermate mice. Small molecule antagonists were used to assess the impact of acute Bcl-2/Bcl-x_L inhibition on mitochondrial physiology, cellular ATP/ADP, calcium signalling and insulin secretion of beta-cells in vitro.
Results: Quantitative real-time PCR and western blot confirmed the near complete loss of Bcl-x_L expression and protein in islets from inducible Bcl-x KO mice. Loss of islet Bcl-x resulted in a moderate improvement of glucose tolerance in 10-12 week old mice within days of tamoxifen administration. The cellular ATP-to-ADP ratio of Bcl-x KO islet cells was markedly increased in the presence of both basal and stimulatory glucose. Moreover, cytosolic calcium responses were significantly enhanced in glucose-stimulated islets and dispersed beta-cells from both Bcl-x_L and Bcl-2 deficient animals relative to their respective controls. In accordance with these findings, acute treatment of normal mouse and human islet cells with Bcl-2/Bcl-x_L antagonists in the presence of 3 mM glucose enhanced basal glucose-dependent respiration and induced mitochondrial calcium fluctuations within minutes. This raised ATP/ADP and triggered K_{ATP} channel- and voltage-dependent calcium influx and insulin secretion. Sustained Bcl-2/Bcl-x_L inhibition resulted in beta-cell death but detailed time-course analyses demonstrated the induction of apoptosis to be temporally and causally disconnected from the observed physiological responses.
Conclusion: Our findings demonstrate that anti-apoptotic Bcl proteins exert a tonic suppression of beta-cell metabolic signalling and thus work at the interface of beta-cell survival and physiology. Further study of these survival-regulating proteins and the molecular mechanisms of their metabolic functions may help identify factors to preserve the functional beta-cell mass required to maintain glucose homeostasis.

The endocannabinoid system links gut microbiota to adipogenesis

P.D. Cani[1], D. Naslain[1], F. Bäckhed[2], C.S. Reigstad[2], D.M. Lambert[1], N.M. Delzenne[1], G.G. Muccioli[1];
[1]LDRI, Univeristé Catholique de Louvain, Brussels, Belgium, [2]University of Gothenburg, Sweden.

Background and aims: Obesity is characterized by a massive expansion of the adipose tissue associated with a low-grade inflammation. Recently, we and others have proposed that gut microbiota would favour the occurrence of inflammation, insulin resistance and metabolic diseases associated with obesity. We have demonstrated a connection between the gut microbiota, fat mass, gut permeability and inflammation associated with higher plasma LPS levels (metabolic endotoxaemia). The endocannabinoid-system (eCB) plays a major role in the development of the inflammation and metabolic disorders associated with obesity via mechanisms not fully understood. Interestingly, LPS is known to stimulate eCB system tone. Therefore, we postulate that the higher plasma LPS levels and eCB system-tone found in obesity could act as key mechanisms leading to gut barrier disruption and altered adipogenesis.
Materials and methods: To determine the contribution of gut microbiota on the regulation of the intestinal and adipose tissue eCB-system tone (CB_1 mRNA, FAAH mRNA, AEA) in both physiological and obese conditions, we investigated selective (prebiotics, high-fat), drastic (antibiotics, germ-free mice) modulation of the gut microbiota and bacteria-host interaction (*Myd88*$^{-/-}$) models. To investigate the role of the eCB-system tone, we blocked the CB_1 receptor with a specific and selective antagonist (SR141716A) in obese *ob/ob* mice, or we mimicked the higher eCB-system tone observed during obesity by chronic (4-weeks) infusion of a CB receptor agonist (HU-210). We investigated *in-vivo* and *in-vitro* intestinal permeability, adipocyte differentiation (PPAR-γ, aP2, C/EBP-α) and lipogenesis (SREBP-1c, ACC, FAS) and the occurrence of inflammation (plasma LPS, cytokines) in the different models.
Results: Obese mice (genetic and nutritional models) are characterized by a higher intestinal and adipose tissue eCB system tone (higher AEA content and CB_1 mRNA expression, lower FAAH mRNA). We found that the gut microbiota directly controls the intestinal eCB system-tone in all five models of gut microbiota modulation. We found *in-vitro* and *in-vivo* that the activation of the intestinal eCB-system increases gut permeability (higher plasma LPS and plasma Dextran-FITC, alteration of tight junctions proteins ZO-1 and Occludin). We demonstrated that the blockade of the CB_1 receptor reduced plasma LPS levels by a mechanism linked to the improvement of these markers. At the adipose tissue level, we show both *in-vitro* and *ex-vivo* that both eCB system and gut microbiota regulates adipogenesis, by increasing markers of differentiation (PPAR-γ, aP2, C/EBP-α) and lipogenesis (SREBP-1c, ACC, FAS). In addition, we found that LPS acts as a key regulator on the endocannabinoid and PPARγ-driven adipogenesis.
Conclusion: First, we demonstrate that the peripheral (intestine and adipose tissue) eCB-system tone is under the control of the gut microbiota. Second, we demonstrate that eCB-system controls gut barrier function and therefore endotoxaemia. Third, we provide evidence that adipogenesis is under the control of the gut microbiota, through the modulation of the gut and adipose tissue endocannabinoid systems. These data indicate that gut microbiota determines adipose tissue physiology through LPS-eCB system regulatory loops and may play a critical role in the adipose tissue plasticity during obesity.

Depot-specific induction of transdifferentiation, inflammation and apoptosis via cannabinoid type 1 receptor blockade

I. Wagner, N. Perwitz, M. Drenckhan, H. Lehnert, J. Klein;
Internal Medicine, Universität zu Lübeck, Germany.

Background and aims: The endocannabinoid system is a major component in the control of energy metabolism. CB1-receptor blockage induces weight loss and reduces the risk to develop the metabolic syndrome with its associated cardiovascular complications. These effects are mediated by central and peripheral pathways. Interestingly weight loss is mainly achieved by a reduction of visceral fat mass. Therefore we investigated fat depot-specific differences on adipocyte differentiation, inflammation, and oxidative metabolism in CB1-receptor knockout cells.
Materials and methods: We used newly generated inguinal and epididymal adipose cell lines from CB1-R knockout mice. Differences in differentiation were measured by fat specific oil red o staining and quantitative RT-PCR-based mRNA expression analysis of key differentiation markers. Induction of apoptosis was evaluated by using a cell death detection ELISA and performing protein analysis of p53 phosphorylation. Inflammation markers were quantified on RNA level. For analyzing the process of transdifferentiation we measured oxygen consumption and mitochondrial biogenesis.
Results: Differentiation was reduced in visceral adipocytes from CB1-receptor knockout mice as compared to wildtype controls. All markers of late differentiation, including AP2, GLUT 4 and PPAR gamma were decreased in these CB1-R-KO cells. Moreover, the inhibitory preadipocyte factor, Pref-1, was elevated. Furthermore, we found a significant induction of apoptosis (increased by 51%) in these cells from the visceral fat depots. In contrast, subcutaneous cells from CB1-R knockout mice showed an accelerated differentiation as well as a reduced induction of apoptosis (decreased by 41%). Inflammation was increased in visceral fat cells, as analyzed by the expression pattern of IL-6 (+357%), MCP-1 (+326%), TNF α (+371%), whereas in subcutanous adipocytes these markers were declined by -60%, -26%, -32% respectively. In addition, subcutaneous CB1-R knockout cells were more sensitive towards a conversion into a brown fat phenotype. UCP-1 expression in these cells was significantly elevated by 176% in preadipocytes and 285% in fully differentiated adipocytes. Moreover, PGC-1 α expression was augmented by 152% and by 140%, respectively. Finally, we found an increase in mitochondrial biogenesis demonstrated by mitochondrial fluorescence staining and RNA expression pattern of TFAM and NRF-1 in these cells. In line with these data, there was also an increase in oxygen consumption by 83% in subcutaneous preadipocytes as well as an 92% enhancement in fully differentiated cells compared to wildtyp controls.
Conclusion: In conclusion, we found depot-specific effects on differentiation, apoptosis, inflammation and oxidative metabolism in CB1-receptor knockout cells. Visceral adipocytes showed a lack of differentiation and an enhancement of apoptosis. In contrast to visceral fat cells, subcutaneous cells expressed an antiinflammatory cytokine profile and were more sensitive towards a conversion into a brown fat cell phenotype. Thus, CB1 receptor-mediated pathways differentially target adipose tissue depots to a dual effect that minimizes cardiometabolic risk, on the one hand, by diminishing fat, and that enhances thermogenesis in subcutaneous adipocytes, on the other.

Portal IL-6 determines the effect of fat tissue transplantation on glucose homeostasis

J.M. Rytka[1,2], S. Wueest[1,2], E.J. Schoenle[1], D. Konrad[1,2];
[1]Division of Diabetology und Endocrinology, University Children's Hospital Zurich, [2]Zurich Center for Integrative Human Physiology, University of Zurich, Switzerland.

Background and aims: Visceral obesity has been associated with insulin resistance, however the molecular mechanisms relating visceral fat accumulation and hepatic insulin resistance (portal theory) are still not well known. The portal theory implicates increased drainage of pro-inflammatory cytokines and lipids from portal drained adipose tissue directly to the liver. We applied herein a novel adipose tissue transplantation approach to investigate a potential effect of adipose tissue localization and in particular of venous drainage (caval versus portal) on glucose metabolism. Moreover, we hypothesized that IL-6 is a major contributor to hepatic insulin resistance associated with visceral fat accumulation.
Materials and methods: Epididymal fat pads of six weeks old C57Bl6J donor mice were transplanted either to the mesenterium (portal venous drainage) or to the peritoneum (caval venous drainage) of healthy littermates. Sham-operated mice were used as control. After five weeks of transplantation glucose metabolism was assessed by glucose tolerance test (2g/kg body weight) and by hyperinsulinemic-euglycemic clamp.
Results: Mice receiving a portal-drained fat transplant developed impaired glucose tolerance compared to mice receiving a caval-drained transplant ($p< 0.001$) and to sham-operated ($p<0.01$) mice. In portal transplanted mice, glucose infusion rate (GIR) and insulin-mediated inhibition of hepatic glucose production (HGP) during hyperinsulinemic-euglycemic clamp was reduced compared to sham-operated mice ($p< 0.05$) demonstrating the development of hepatic insulin resistance in portal transplanted mice. This was also con-

firmed by reduced insulin-stimulated Akt phosphorylation ($p< 0.01$) in livers of portal transplanted mice. In contrast, hepatic lipid content and Kupffer cell activation was not different. Interestingly, Fas-ligand and interleukin-6 mRNA expression was increased in portal transplanted fat pads. Moreover, IL-6 levels of portal transplanted mice were elevated in portal compared to systemic plasma samples whereas no difference was found in sham-operated mice. Intriguingly, mice receiving a portal drained IL-6-deficient fat transplant showed normal glucose tolerance and hepatic insulin sensitivity. In addition, expression of pro-inflammatory cytokines was significantly reduced in IL-6-deficient transplants.
Conclusion: These results demonstrate an important role for venous drainage of adipose tissue on glucose homeostasis. In addition, IL-6 seems to play a major role in the development of hepatic insulin resistance associated with visceral fat accumulation.

Hyperactivation of inflammasome-mediated caspase-1: a new mechanism underlying increased inflammatory activity in visceral adipose tissue
T.B. Koenen, R. Stienstra, B. van Tits, M.G. Netea, C.J. Tack, A.F.H. Stalenhoef, J. de Graaf;
General Internal Medicine, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: Abdominal adipose tissue, stored viscerally (VAT) or subcutaneously (SAT), is metabolically active and secretes a wide variety of adipokines and cytokines. It has been suggested that VAT possesses more pro-inflammatory properties characterized by an enhanced release of cytokines as compared to SAT. The pro-inflammatory trait of VAT may account for its stronger correlation with insulin resistance, relative to SAT. The inflammatory IL-1 family members IL-1β and IL-18 are increased in obese subjects and negatively affect insulin signaling. The inactive pro-forms of both cytokines are processed into active IL-1β and IL-18 by a cysteine protease called caspase-1. Activation of this enzyme is mediated by the inflammasome, which involves formation of a complex between NOD like receptors and the adapter protein ASC. In this study, we assessed the presence of the inflammasome in human adipose tissue and tested whether inflammasome-dependent caspase-1 activation is more dominant in abdominal VAT compared to SAT.
Materials and methods: Paired abdominal SAT and VAT biopsies were obtained from ten mildly obese subjects (BMI: 25-28 kg/m^2; aged 40-60 years). Intact adipose tissue fragments were immediately cultured for 24 hours from both depots after which medium, RNA, and protein lysates were collected to determine the expression of the inflammasome components and the secretion levels of pro-inflammatory cytokines.
Results: *Ex-vivo* experiments using adipose tissue explants cultures revealed a higher release of bioactive IL-1β (10-fold; $P < 0.05$) and IL-18 (4-fold; $P < 0.05$) from VAT compared to SAT. The increased secretion of both cytokines was significantly reduced when caspase-1 activity was blocked by the specific inhibitor pralnacasan. Although caspase-1 protein was expressed in both adipose tissue depots, western blot analyses and caspase-1 activity assays revealed a 3-fold ($P <0.05$) up-regulation of active caspase-1 protein in VAT in line with the enhanced production of IL-1β and IL-18. In addition to the augmented caspase-1 activity, protein levels of the inflammasome complex members ASC and the Nod like receptor NLRP3 were significantly higher in VAT. Fractioning of VAT into mature adipocytes and stromal vascular cells revealed that caspase-1 gene expression mainly originates from adipocytes, while ASC was found to be more expressed in the stromal vascular cells. Concurrent with the enhanced bioactive IL-1β secretion, IL-6 and IL-8 release was also induced (3-fold; $P < 0.05$ and 4-fold; $P < 0.05$, respectively) in the VAT explants while adiponectin secretion was two times lower ($P < 0.05$).
Conclusion: Our results show that NLRP3 inflammasome components and caspase-1 are present in human abdominal adipose tissue and are highly activated in VAT compared to SAT, resulting in an enhancement of IL-1β and IL-18 secretion. These findings imply that inflammasome-dependent caspase-1 activation contributes to the pro-inflammatory status of VAT.

The role of TGF-beta/Smad3 signalling in the pathogenesis of obese fat tissue
Y. Tsurutani, M. Fujimoto, M. Takemoto, K. Yokote;
Department of Diabetes, Metabolism, and Endocrinology, Chiba University Graduate School of Medicine, Chiba, Japan.

Background and aims: Obesity is serious problem because it causes many kind of life-style related illness, such as type2 diabetes, hypertension, and dyslipidemia. In recent years, obesity is recognized to closely associate with inflammation, because hypertrophic visceral adipose tissue secretes a variety of inflammatory cytokines that lead to insulin resistance. TGF-β has a wide range biological effect, differentiation, proliferation, immunomodulation, and so on. We have previously reported the role of TGF-β on atherosclerosis and diabetic nephropathy, using mice lacking Smad3, a major mediator of TGF-β signaling. TGF-β is known to have inhibitory effect for adipocytogenesis, but the detail molecular mechanism is not fully understood. On the other hand, several studies have shown that cross-talk between TGF-β/Smad3 and Wnt-β-catenin signaling, also known to have inhibitory effect for adipocytogenesis, plays important roles in the regulation of cell differentiation. In this study, we aimed to clarify the role of TGF-β/Smad3 signaling in the pathogenesis of obese fat tissue, and investigate the role of cross-talk between TGF-β/Smad3 and Wnt/β-catenin signaling in adipocytogenesis.
Materials and methods: (1) In order to clarify the expression of TGF-β/Smad3 signaling in obese fat tissue, we isolated epididymal white adipose tissue of 12-week old obese *ob/ob* mice and wild type (WT) mice, and analyzed the expression of mRNA and protein related to TGF-β/Smad3 signaling. (2) To clarify whether TGF-β inhibits adipocytogenesis dependent on Smad3, WT and Smad3 KO (KO) mouse embryonic fibroblasts (MEFs) were induced to differentiate into adipocyte with or without 1 ng/ml TGF-β. (3) To clarify the role of cross-talk between TGF-β/Smad3 signaling and Wnt-β-catenin signaling in adipocytogenesis, WT and KO MEFs were stimulated with 1 ng/ml TGF-β, and then evaluated the translocation of β-catenin into nucleus. Moreover, HW preadipocytes were infected with retrovirus carrying empty vector or cby, an antagonist of β-catenin, and then differentiated into adipocytes with or without 1 ng/ml TGF-β. (4) To clarify the role of TGF-β/Smad3 signaling *in vivo*, eight-week-old WT and KO mice were fed high fat diets for 8 weeks. The food intake and body weight were recorded. After 8 weeks, we performed insulin tolerance test and isolated epididymal WAT for histological and genetic analyses.
Results: (1) mRNA and protein expression of TGF-β, and phosphorylation of Smad3 were increased in the epididymal WAT of *ob/ob* mice. (2) TGF-β suppressed adipocyte differentiation on WT MEF, but this inhibitory effect was attenuated on KO MEF. (3) TGF-β promoted translocation of β-catenin into nucleus on WT MEF, but this effect was attenuated on KO MEF. On the other hand, TGF-β suppressed adipocyte differentiation almost completely not only on empty vector infected HW cells but also on cby-infected HW cells. (4) Despite the amount of food intake was similar between two groups, the percent increase in the body weight was significantly larger in KO mice. KO mice were more insulin-sensitive than WT mice. WAT from KO displayed a larger number of adipocytes with a smaller cell diameter.
Conclusion: TGF-β is highly expressed in obese fat tissue, and it inhibits adipocytogenesis via Smad3 and contributes to development of insulin-resistance. TGF-β emphasizes Wnt-β-catenin signaling, but its inhibitory effect on adipocytogenesis may be not dependent on Wnt-β-catenin signaling.

PI3Kγ in non-hematopoietic cells plays a major role in the promotion of obesity, inflammation and glucose intolerance
G. Solinas[1], R. Marone[2], B. Becattini[1], F. Zani[1], A. Dulloo[1], J.-P. Montani[1], F. Preitner[3], M.P. Wymann[2];
[1]Department of Medicine, Physiology, University of Fribourg, [2]University of Basel, [3]Center for Integrative Genomics, University of Lausanne, Switzerland.

Background and aims: Obesity is associated with a state of chronic low-grade inflammation (metabolic inflammation), which is believed to play an important role in the pathogenesis of obesity and type-2 diabetes. Metabolic inflammation is characterized by leukocyte infiltration into obese adipose tissue, and polarization of T-cells and macrophages toward a more pro-inflammatory cellular population. The lipid kinase phosphoinositide 3-kinase γ (PI3Kγ) has previously been shown to be central in leukocyte chemotaxis

in different models. Furthermore PI3Kγ was shown to play a major role in β-adrenergic receptors signaling within cardiomyocytes, and in angiotensin II signaling in vascular cells. Therefore PI3Kγ is a likely candidate signal transducer at the interface between inflammation and metabolism. In this study we investigated the role of PI3Kγ in diet-induced obesity, metabolic inflammation, and insulin resistance.
Materials and methods: C57BL/6J mice (wt) and mice with a targeted Pi3kγ locus (Pi3kγ-/-) were exposed to a high-fat diet (60% of calories from fat) for 16 weeks. Body weight was measured weekly to determine growth curves. Analysis of body composition, energy balance, in-vivo and ex-vivo calorimetry were performed. To test the role of PI3Kγ in glucose homeostasis and insulin sensitivity we performed glucose tolerance test, insulin tolerance test, and hyperinsulinemic-euglycemic clamp. To learn about the cell-type implicated in the metabolic action of PI3Kγ we have generated mice lacking PI3Kγ either in hematopoietic or non-hematopoietic cells by adoptive transfer. To test the role of the kinase dependent and independent functions of PI3Kγ we have investigated mice expressing a mutated form of PI3Kγ where its kinase function is selectively blocked (Pi3kγKD/KD). Gene expression profiling was performed by DNA microarrays, and by real-time PCR.
Results: When placed on chow diet, wt and Pi3kγ-/- mice display a similar phenotype. However, when fed with high-fat diet Pi3Kγ-/- mice are resistant to diet-induced obesity, mainly because of increased energy expenditure. Insulin and glucose tolerance were markedly improved in Pi3kγ-/- animals versus wt mice, and hyperinsulinemic-euglycemic clamp revealed a four-fold increase in insulin sensitivity in Pi3kγ-/- mice compared to controls. Metabolic inflammation was also markedly decreased in Pi3kγ-/- mice compared to wt mice. Bone marrow transplantation experiments mapped the role of PI3Kγ in diet-induced obesity,-inflammation, and -glucose intolerance in the non-hematopoietic compartment. When placed on high-fat diet Pi3kγKD/KD mice also showed a leaner phenotype, improved glucose homeostasis, and decreased inflammation compared to wt mice.
Conclusion: We demonstrate here for the first time that the PI3Kγ activity in non-hematopoietic cells plays a major role in the promotion of diet-induced obesity, metabolic inflammation, and insulin resistance by a molecular mechanism involving its kinase activity.

Thirty years of prospective nationwide incidence of childhood type 1 diabetes: the accelerating increase by time tends to level off in Sweden
Y.T. Berhan[1], I. Waernbaum[2], T. Lind[1], A. Möllsten[1], G.G. Dahlquist[1];
[1]Clinical Sciences, Pediatrics, [2]Statistics, Umea University, Sweden.

Background and aims: A rising incidence in childhood type-1 diabetes (T1D) has been reported from many countries during the last 20 years. Second to Finland, Sweden has the highest reported nationwide incidence of T1D in the world (>40/100.000). Over a 20 year period (1978 - 1997) the incidence of T1D among ages <15 yrs was almost doubled in Sweden, with the largest increase among children aged 0-5 yrs. The change over time has been partly explained by changes in lifestyle causing rapid early growth and weight development. In the present 30 yr follow up (1978 - 2007) of the Swedish Childhood Diabetes Register we describe the current time trend by age, sex and birth cohort, and analyze the changes in incidence using statistical models. We also aim to discuss the possibility to predict numbers of new cases of childhood onset T1D using generalised models over long periods of time. For discussion we also examine possible correlations between time trend in T1D incidence and indicators that mirror calorie-intake.
Materials and methods: The Swedish Childhood Diabetes Registry has recorded cases of childhood onset T1D (0-14yrs) since 1 July 1977 with a high level of coverage (96-99% of cases). This study is based on 14 721 incident cases of childhood onset T1D occurring 1 Jan 1978-31 Dec 2007. Incidence numbers were calculated after extracting population data from Statistics Sweden. Official population projections were used to predict numbers of new cases in Sweden in 2017, 2027 and 2037. Generalized additive models were fitted for Poisson distributions and the impact of calendar year at onset in five years age groups, sex and interaction terms were tested. Model coefficients with significant goodness of fit were used for the prognosis of the trends in incidence. Finally a coefficient of determination was calculated to determine the extent to which incidence of child hood onset T1D and yearly soft drink consumption could be related.
Results: Age and sex specific incidence rates varied from 21·6 (95 % CI 19·4 - 23·9) during 1978-1980 to 43·9 (95 % CI 40·7 - 47·3) during 2005-2007. Cumulative incidence shifted to younger age at onset over the first 22 years, but from the birth year 2000 a reversed trend was seen. Using a model including all calendar years, age and sex the predicted number of incident cases may more than triple the next 30 years period (648 in 2007 and 2294 in 2037). An ecological analysis using soft drink consumption as a marker for eating habits and high energy intake showed a strong correlation with incidence rate in Sweden (R^2= 0·84).
Conclusions: Childhood T1D increased dramatically and shifted to younger age at onset the first 22 years of the study period, but since year 2000 for the first time we report a reversed trend. The predicted almost tripling of incident cases over the next 30 years is thus probably an overestimation. No distinct conclusions can be made from the ecological analysis, but the strong correlation between increasing soft drink consumption and increasing trend of T1D add an interesting contribution to the discussion.

The changing natural history of type 1 diabetes: contrasts between those diagnosed in the 1960s and 1970s
T.J. Orchard, R.G. Miller, T. Costacou;
Epidemiology, University of Pittsburgh, USA.

Background and aims: Individuals with type 1 diabetes (T1D) face a number of different complications, or outcomes, and thus it is important to view, from a management perspective, a broad combination of major outcomes of diabetes (MOD). Little is known concerning the cumulative risk of MOD for childhood onset T1D and to what extent this may have declined with improved care.
Materials and methods: To examine these changes, data from the 22 year historical prospective Pittsburgh Epidemiology of Diabetes Complications study of childhood onset (<17 years) T1D diabetes were used. Participants,

diagnosed between 1960 and 1980 at Children's Hospital of Pittsburgh, were grouped by year of diabetes diagnosis (1960-1969, n=321 and 1970-1980, n=368). MOD was defined as diabetes-related death, CAD (MI, revascularization), stroke, end-stage renal disease, amputation or blindness. Cumulative incidence estimates (figure) were calculated using Weibull accelerated failure-time modeling.
Results: By 25 years of diabetes duration, 34% (110) of individuals from the 1960s cohort had experienced such events (5% had died, 6% had CAD, 2% stroke,12% ESRD, 8% blindness, 1% amputation) while for the 1970s cohort only 18% had suffered a MOD (3% had died, 2% had CAD, <1% stroke, 2% ESRD, 9% blindness, 2% amputation). These observed cumulative incidences were close to those predicted using Weibull models, which estimated that 31% (95% CI 27.4, 35.8) of the 1960s cohort and 20% (95% CI 16.7, 23.9) of the 1970s cohort would have an MOD event by 25 years of T1D duration (p=0.0001). The majority of the care for the 1960s cohort was before the advent of self-monitoring of blood glucose and HbA1c testing, while the reverse is true of the 1970s cohort.
Conclusion: While these results suggest encouraging falls in many components of MOD, it is striking that no reduction is seen for blindness or amputation, which together now account for 60% of MOD events in the first 25 years of T1D in the 1970s cohort as opposed to only 27% in the 1960s. Further attention should be paid to the total morbidity burden of those with T1D and to understanding why blindness and amputation are not being delayed or prevented.

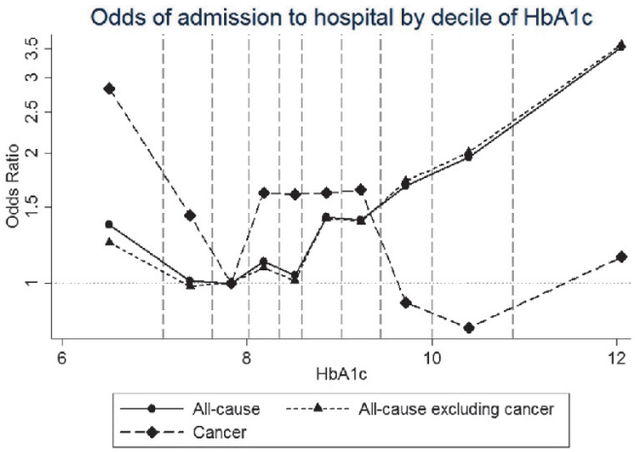
HbA_{1c} levels and hospital admission in people with type 1 diabetes
L. Govan, The Scottish Diabetes Research Network Epidemiology Group; Public Health and Health Policy, University of Glasgow, United Kingdom.

Background and aims: There has been recent concern that very tight glycaemic control might be associated with an increase in morbidity in people with diabetes. We assessed the relationship between deciles of HbA1c and hospital admissions in patients with type 1 diabetes.
Materials and methods: The Scottish Care Information - Diabetes Collaboration (SCI-DC) is a dynamic national register of diagnosed cases of diabetes in Scotland. These data were linked to centralised data on hospital admissions from Information Services Division (ISD) of NHS National Services. We identified 24,760 people with type 1 diabetes during January 2005 to December 2007 and include 19,777 patients with complete recording of covariates. Patients were divided into deciles according to levels of HbA1c. All-cause admission to hospital was the primary outcome. Logistic regression models were used to estimate the association between HbA1c and all cause admissions expressed with decile 3 (mean HbA1c 7.8%, range 7.6%-8.0%) as referent and adjusted for potential confounding factors including age, sex, previous vascular disease, creatinine, body mass index and diabetes duration.
Results: 8.1 % of people had HbA1c <7.0% and 16.2% under 7.5%. There was a J-shaped relationship of HbA1c to all hospital admissions with highest likelihood of admission (adjusted odds ratio 3.54, 95%CI 3.04-4.12) in the highest HbA1c decile (12.1%; 10.8-18.4%) but also increased admissions (adjusted OR 1.36, 95%CI 1.13-1.64) in the lowest HbA1c decile (6.5%; 4.4-7.1%). Cancer admissions showed a broadly inverse relationship with HbA1c (adjusted OR 2.38, 95%CI 1.33-6.03) in the lowest decile of HbA1c, see Figure. Vascular admissions showed a positive relationship with HbA1c with significantly higher likelihood of admission in HbA1c deciles 7 through 10 (9.03-18.4%). Likelihood of vascular admission was not significantly increased in the lowest decile of HbA1c (adjusted OR 1.10, 95%CI 0.65-1.87) and an increase in all cause admissions remained even after excluding admissions due to cancer and hypoglycaemia (adjusted OR 1.26, 95%CI 1.07-1.49).
Conclusion: Low and high mean HbA1c values were associated with increased admission to hospital with lowest rates of admission for any cause in deciles 2 through 5 (HbA1c 7.1-8.7%) People with the lowest levels of HbA1c had an increase in cancer admissions and this likely reflects reverse causality in this observational dataset. However, an increase in admissions remains even after exclusion of cancer and hypoglycaemic admissions. Overall the likelihood of admissions increases markedly with HbA1c and the highest levels of HbA1c marks out a group with high likelihood of admission and attendant hospital costs.



220

Time trends of mortality in patients diagnosed with type 1 diabetes below 30 years between 1970-1999 in Finland
V. Harjutsalo[1,2], C. Forsblom[1,3], P.-H. Groop[1,3];
[1]Folkhälsan Institute of Genetics, Folkhälsan Research Centre, Biomedicum Helsinki, [2]National Institute of Health and Welfare, Diabetes Prevention Unit, Helsinki, [3]Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, Finland.

Background and aims: Despite of great advances in the diabetes care, type 1 diabetes (T1D) is still associated with a premature mortality due to both acute and long-term diabetic complications. The aim of this study was to assess long-term time trends in mortality among patients diagnosed with early-onset (0-14 years) and late-onset (15-29 years) T1D in Finland. In addition, we aimed to study causes of deaths addressing the changes in the mortality over time.
Materials and methods: Individuals diagnosed with T1D during 1970-1999 (n=17,306) were identified from the Finnish nationwide population-based registers. Vital status and causes of deaths were obtained from the Finnish Cause of Death Register until the end of 2007. Patients were stratified into subcohorts by the year of diagnosis: 1970-74, 1975-79, 1980-84, 1985-89, 1990-94 and 1995-99. Cumulative mortalities were evaluated using Kaplan-Meier method. Crude mortality (per 100,000 person-years) and standardized mortality rates (SMR) were calculated. Time trend evaluation in the SMRs was performed by means of Poisson regression modeling.
Results: A total of 1,338 deaths were observed during 370,733 person-years of follow-up giving an all-cause mortality rate of 361 (342-382). The crude mortality was higher in the late-onset than in the early-onset cohort; 531 vs 245. However, the SMR was similar, 2.9 (2.6-3.1) in the early-onset and 2.7 (2.6-2.9) in the late-onset cohort. Women had higher SMR in both cohorts, 3.8 (3.4-4.1) and 3.5 (3.0-4.0), compared to men, 2.5 (2.3-2.6) and 2.4 (2.2-4.7). Overall cumulative mortality at 35 years of duration of diabetes was 17.9% (17.0-18.8). There was no beneficial development in the long-term prognosis by diagnosis years. However, a decreasing trend was seen in the 20-year cumulative mortality in the early-onset cohort from 4.7% (3.7-5.8) to 4.3% (3.3-5.2), 3.6% (2.8-4.5) and 2.7% (1.9-3.4) in the subcohorts 1970-74, 1975-79, 1980-84 and 1985-89. The SMR at 20 years duration of diabetes decreased

from 2.6 (2.0-3.2) to 1.5 (0.8-2.2) from 1970-74 subcohort to 1985-89 (p for trend 0.07). There was, however, an inverse trend in the late-onset cohort with corresponding rates 4.4% (3.3-5.6), 5.9% (4.6-7.1), 6.5% (5.1-7.8) and 7.9% (6.4-9.4). The SMR increased from 1.3 (1.0-1.7) to 2.7 (2.0-3.3) from 1970-74 to 1985-89 (p for trend 0<0.001). At 20-years of duration of diabetes chronic diabetic complications explained 38% of the deaths in the 1970-74 subcohort decreasing to 17% in the 1985-89 subcohort among those with early-onset diabetes. In the late-onset cohort mortality decreased from 58% to 26%. The proportion of alcohol and drug related deaths was high in the early-onset diabetes, appr. 25%, while it increased to 39% in the late-onset cohort. SMR for alcohol-related deaths was 4.4 (3.1-5.7) and 2.7 (2.2-3.3) in the early and late-onset cohorts and was equal for men and women. SMR for suicides was significant only in women with early-onset diabetes, 3.3 (1.9-4.7).
Conclusion: We found improvement in survival of people with early-onset T1D. On the contrary, individuals with late- onset T1D showed worse survival after the 1980s compared to the 1970s. Reduction in chronic diabetic complications was, however, replaced by alcohol- and drug-related mortality.

Intensive glucose control is renoprotective in type 2 diabetes: New analyses from ADVANCE

S. Zoungas[1], J. Chalmers[1], A. Patel[1], M. Marre[2], C.E. Mogensen[3], L. Billot[1], Q. Li[1], M.E. Cooper[4], on behalf of the ADVANCE Collaborative Group;
[1]The George Institute for International Health, The University of Sydney, Australia, [2]Hôpital Bichat-Claude Bernard and Université Paris 7, France, [3]Aarhus Sygehus, Denmark, [4]Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Background: Blood glucose is an important determinant of kidney disease among patients with type 2 diabetes. In these analyses we determine the effects of intensive glucose lowering, targeting an HbA1c of less than or equal to 6.5%, a level below the currently recommended targets, on a range of renal outcomes among 11,140 patients who had type 2 diabetes and participated in the Action in Diabetes and Vascular disease: preterAx and diamicroN-MR Controlled Evaluation (ADVANCE) study.
Methods: Patients were randomly assigned to intensive glucose control based on the use of gliclazide MR and other therapy as required to achieve an HbA1c level less than or equal to 6.5%, or standard glucose control. Treatment effects on total renal events, new or worsening nephropathy, new-onset microalbuminuria (UACR 30 to 300 g/mg), new-onset macroalbuminuria (UACR >300 g/mg), progression of albuminuria by at least 1 stage (from normoalbuminuria to either micro- or macroalbuminuria or from micro- to macroalbuminuria) and regression of albuminuria by at least 1 stage, were assessed.
Results: After a median follow-up of 5.0 years, the mean HbA1c level achieved in the intensive control group was 6.5% as compared with 7.3% in the standard control group. As compared to standard glucose control, intensive glucose control reduced the risk for total renal events by 11% (95% CI =(5%-17%), *P*<0.001), new or worsening nephropathy by 21% (95% CI, 7-34%,p=0.006), new-onset microalbuminuria by 9% (95% CI, 2-5%, p=0.018), new-onset macroalbuminuria by 30% (95% CI, 15-43%, P<0.001) and progression of albuminuria by 10% (95% CI, 2-16%, p=0.028). In patients with albuminuria at baseline, regression by at least one stage occurred in 62% of intensively treated patients, with the majority achieving normoalbuminuria. Compared to standard glucose control, intensive glucose control increased regression of albuminuria by 15% (95% CI, 5-26%, P<0.002). Effects of active treatment on total renal events were consistent across subgroups defined by median HbA1c level at baseline (p for interaction>0.1).
Conclusion: The gliclazide MR-based intensive glucose control regimen, aiming for an HbA1c level less than or equal to 6.5% in patients with established type 2 diabetes, provided renal benefits including regression or normalisation of albuminuria. This renoprotection, is evident even among those with initial HbA1c levels < 7% and we could not identify an HbA1c threshold below which renal benefit was lost.

Prevention of microalbuminuria in type 2 diabetes (ROADMAP Trial)

H. Haller[1], E. Ritz[2], L. Ruilope[3], T. Rabelink[4], G. Viberti[5], for the ROADMAP Steering Committee;
[1]Medical School Hannover, [2]University of Heidelberg, Germany, [3]Hospital 12 de Octubre, Madrid, Spain, [4]Leiden University Medical Center, Netherlands, [5]King's College London School of Medicine, United Kingdom.

Background and aims: Microalbuminuria is an early sign of diabetic nephropathy and increased cardiovascular risk. We investigated whether early treatment with an angiotensin receptor blocker (ARB) in diabetic subjects with normal albumin excretion delays the occurrence of microalbuminuria and concomitantly recorded cardiovascular and renal events.
Materials and methods: We studied 4,447 patients with type 2 diabetes and at least one additional cardiovascular risk factor in a randomized, double-blind, multicentre, controlled, and event-driven (onset of microalbuminuria) trial. They received either 40 mg olmesartan or placebo once daily for a median duration of 3.2 years. In both groups, additional antihypertensive drug treatment (except ACE inhibitors or ARBs) was used to reach the target blood pressure of <130/80 mmHg.

Results: Baseline eGFR, blood pressure and cardiovascular disease (CVD) risk profiles were comparable in both groups. Nearly 80% of the subjects in the olmesartan group and 71% in the placebo group achieved target blood pressure at month 48. Kaplan-Meier analysis showed a cumulative incidence of microalbuminuria of 8.2% (n=178) with olmesartan and 9.8% (n=210) with placebo which represents a risk reduction of 23% (HR: 0.77; 95.1% CI: 0.63 to 0.94; p= 0.01) in favour of subjects receiving olmesartan. At study end eGFR was lower in the olmesartan-treated subjects (80.1 vs. 83.7 mL/min/1.73 m^2, p<0.001). In both groups 23 subjects had a doubling of the baseline serum creatinine. Overall cardiovascular morbidity and mortality rate was low and similar between groups with cardiovascular morbidity events in 81 (3.6%) and 91 (4.1%) patients, and total mortality in 26 (1.2%) and 15 (1.7%) on olmesartan and placebo, respectively (p> 0.1). Cardiovascular mortality however was higher (15 (0.7%) vs. 3 (0.1%); p= 0.01) in the olmesartan group, possibly due to hypotensive episodes in subjects with pre-existing CVD.
Conclusion: In subjects with type 2 diabetes and excellent blood pressure control early treatment with the ARB olmesartan showed a significant risk reduction regarding the 'time to onset of microalbuminuria'. ClinicalTrials.gov ID no.: NCT00185159.

Renin angiotensin system blockade is effective in preventing microalbuminuria in hypertensive but not normotensive people with type 2 diabetes; further analysis of the DIRECT Programme
R.W. Bilous[1], H.-H. Parving[2], T.J. Orchard[3], R. Klein[4], M. Porta[5], J. Fuller[6], A.-K. Sjolie[7], N. Chaturvedi[8];
[1]Academic Centre, James Cook University Hospital, Middlesbrough, United Kingdom, Rigshospitalet, Copenhagen, Denmark, [3]Epidemiology, University of Pittsburgh, [4]Ophthalmology, University of Wisconsin School of Medicine, Madison, USA, [5]Internal Medicine 1, University of Turin, Italy, [6]Epidemiology, University College, London, United Kingdom, [7]Ophthalmology, Odense University Hospital, Denmark, [8]International Centre for Circulatory Health, Imperial College, London, United Kingdom.

Background and aims: Renin angiotensin system (RAS) blockade prevents microalbuminuria in people with type 2 diabetes (T2DM) at high cardiovascular risk. However, most of these studies measured albumin:creatinine ratio on a single spot urine to define microalbuminuria. Using multiple timed overnight collections the DIRECT Programme could not demonstrate a benefit of RAS blockade on the development of persistent (3 of 4 consecutive samples > 20 μg/min) microalbuminuria. We re-analysed our data using the less stringent microalbuminuria definition of a single value >20μg/min to be more consistent with previous studies.
Materials and methods: 1905 people with T2DM and mild/moderate retinopathy were randomised to Candesartan (titrated to 32mg/d) or placebo. At baseline all were normoalbuminuric (median albuminuria 5.5 (IQR 3.5,8.5) μg/min. 62% were hypertensive (mean BP at entry 139/79 mmHg) and 38% normotensive (BP < 130/85, mean 123/75 mmHg). Subjects collected 2 timed overnight urine collections annually for at least 4 years.
Results: The adjusted risk (Hazard Ratio - HR) and (95% CI) for microalbuminuria for Candesartan versus placebo was 0.80 (0.67,0.96) p = 0.016. This beneficial effect was similar in normotensive (HR 0.81 (0.61,1.09) p = 0.166) and hypertensive (0.79 (0.63,0.99) p = 0.037) individuals at baseline although remaining statistically significant only in the latter. In contrast, no beneficial effect of Candesartan was seen using our more stringent definition of persistent microalbuminuria (HR 0.80(0.58,1.11); 0.66(0.40,1.09) ; and 0.91 (0.60,1.40) for the entire group, normotensive and hypertensive subjects respectively; p = NS for all.
Conclusion: Candesartan is effective at preventing microalbuminuria in people with T2DM and hypertension using the looser definition of a single positive sample. No effect was seen in people with T2DM and normal blood pressure. These results highlight the need for careful and standardized definitions of early nephropathy in intervention trials.

Aldosterone reduction during 24 weeks of treatment with aliskiren or placebo added to losartan in patients with type 2 diabetes and nephropathy, an AVOID substudy
F. Persson[1], H.-H. Parving[2,3], J.B. Lewis[4], E.J. Lewis[5], N.K. Hollenberg[6];
[1]Steno Diabetes Center, Gentofte, [2]Medical Endocrinology, Rigshopitalet, Copenhagen, [3]Faculty of Health Sciences, Aarhus University, Denmark, [4]School of Medicine, Vanderbilt University, Nashville, [5]Medical Center, Rush University, Chicago, [6]Brigham and Women's Hospital, Harvard Medical School, Boston, USA.

Background and aims: Aldosterone suppression reduces albuminuria in diabetic and non-diabetic patients, and is known to improve cardiorenal prognosis. This study assessed the effects on urinary aldosterone, plasma renin activity (PRA) and plasma renin concentration (PRC) of direct renin inhibition with aliskiren (ALI) in combination with the ARB losartan (LOS) and optimal antihypertensive therapy in the Aliskiren in the EValuation of PrOteinuria In Diabetes (AVOID) study.
Materials and methods: In the AVOID study, 599 patients aged 18-85 years with hypertension and diabetic nephropathy received 6 months' ALI (150 mg force titrated to 300 mg after 3 months) or PBO added to LOS 100 mg and optimal antihypertensive therapy. Study exclusion criteria comprised non-diabetic kidney disease, urinary albumin:creatinine ratio (UACR) >3500 mg/g, eGFR <30 ml/min/1.73 m^2 and serum potassium >5.1 mmol/l. Urinary aldosterone, PRA and PRC were measured at baseline of the double-blind period and after 24 weeks in a subset of 133 patients.
Results: ALI added to LOS provided large reductions from baseline in urinary aldosterone compared with adding PBO (−24% vs. −4%, p=0.017) at week 24. There was no significant difference between the aliskiren and placebo groups in the proportion of patients with aldosterone breakthrough (ALI 35%, PBO 46%, p=0.199). There was no correlation between change in urinary aldosterone levels and change in UACR or change in systolic blood pressure (SBP). ALI treatment reduced PRA by 90% at 24 weeks (p<0.001); PBO treatment had no significant effect. PRC increased by 228% from baseline with ALI and decreased by 17% with PBO (p<0.001).
Conclusion: Adding ALI to LOS and optimal antihypertensive therapy provided significant, long-term reductions in urinary aldosterone beyond those provided by ARB and optimal antihypertensive therapy. Reduction in PRA by ALI treatment may be a potential mechanism behind the reduction in urinary aldosterone levels.

Acute administration of the GLP-1 receptor agonist, Exenatide, restores impaired central responses to food ingestion in type 2 diabetes

Y. Nathan[1], S. Lee[2], T. Evans[3], S. Coates[3], L.J. Reed[4], M.J. Brammer[2], F.O. Zelaya[2], S.A. Amiel[1];
[1]Diabetes Research Group, King's College London, [2]Brain Image Analysis Unit, Institute of Psychiatry, [3]Paxton Green Health Centre, [4]Institute of Psychiatry, London, United Kingdom.

Background and aims: An appetite control system that allowed continued eating when food is available would be of evolutionary advantage in a hunter-gatherer lifestyle but would predispose to obesity in the modern world. Incretins, such as GLP-1, are secreted by the gastrointestinal tract in response to food ingestion and are involved in the satiety response that terminates eating. Incretin responses to food ingestion are abnormal in obesity and Type 2 diabetes (T2DM) and incretin-based therapies can deliver weight loss and improved diabetic control. The aim of our study was to use the GLP-1 receptor agonist Exenatide to explore the central control of appetite and satiety in people with T2DM, using functional magnetic resonance imaging (fMRI) and the food cue of food image viewing.
Materials and methods: 12 subjects with lifestyle ± metformin treated diabetes (age 55.0 ± 1.8 yrs, BMI 31 ± 1.7, HbA1c 7.1 ± 0.2%) underwent 4 fMRI brain scans, while observing images of food and non-food shown in a block design paradigm, after overnight fast. Satiety and hunger were assessed by visual analogue scales before and after both ingestion and image viewing. On two occasions, subjects consumed a mixed meal (554kcals) as 200 mls chocolate ice cream (FED studies); on two they took 50 mls water to mimic the physical actions of ingestion (FASTED), prior to image viewing. A single subcutaneous injection of either an active GLP-1 receptor agonist (10 mcg Exenatide), or placebo was given immediately prior to each scan. Scans were done in random order with subject and investigator blinded to the nature of the injection. Changes in blood oxygenation level dependent (BOLD) signal collected during image viewing were analysed with XBAM software. Brain regions with changes in activation in response to food image viewing, shown by changes in BOLD signal, were compared using sum of squares (SSQ). Data from 12 healthy volunteers, age 25± 1.2 yrs, BMI 22±0.8 were available for comparison.
Results: Subjects felt more hungry after water in the fasted state (p=0.01), an effect reduced by Exenatide (p<0.01). Visual cortical activation occurred in all subjects and conditions, with BOLD signal change in response to food and non-food images (p=0.9). In contrast, distinctive BOLD signal changes showed activation in the ventral tegmental area (VTA) in T2DM patients observing food images when FED, which were not present FASTED (p=0.036). The activation was reduced in FED by Exenatide (p<0.02 vs FASTED placebo), to a degree not different from the FED non-diabetic data (p=0.70). The T2DM FED response to food image viewing was not different from the non-diabetic FASTED state (p=0.13).
Conclusion: The VTA is central to perception of the reward value of food and in animal studies its responses are affected by insulin. Its activation pattern in T2DM after eating is different from in health, resembling the healthy response to food cues in the fasted state. Acute elevation of incretin action, by Exenatide, restores the reward circuitry response of the early T2DM in the fed state towards normal. The T2DM activation pattern indicates a failure of satiety and would be expected to encourage prolonged eating. Such a mechanism may contribute to obesity in people with insulin resistant diabetes.

Abnormal reward processing towards appetizing food in obesity

L. Nummenmaa[1], J. Hirvonen[2], J. Hannukainen[2], A. Karmi[2], P. Nuutila[2];
[1]Department of Biomedical Engineering and Computational Science, Aalto University, Espoo, [2]Turku PET Centre, Finland.

Background and aims: Comparative studies have identified an interconnected network comprising of subcortical and frontocortical regions in various aspects of reward processing. This reward circuit plays a key role in guiding appetitive behaviours, and its dysfunctions have been associated with obesity. The aim was to study brain metabolism of glucose and the processing of anticipatory food reward in obesity.
Materials and methods: The brains of 19 morbidly obese (age 46±10 years, BMI 43.9±3.7 kg/m^2) and 16 lean individuals (age 48±10 years, BMI 24.1±2.1 kg/m^2) were studied with 2-[^{18}F]fluoro-2-deoxyglucose positron emission tomography (PET) during euglycemic hyperinsulinemia, and with functional magnetic resonance imaging (fMRI) while anticipatory food reward was induced by repeated presentations of appetizing and bland food pictures.
Results: We found that in obese individuals glucose metabolic rate (GMR) of the caudate nucleus was elevated when compared to controls (4, 8, 4, T = 3.97, p = .03 SVC), but not in any other a priori region of interest. Responses to all foods (appetizing and bland) were higher in obese patients than in controls in the left inferior occipital gyrus (-39, 59, -8, T = 3.76, p < .005, unc.), left amygdala (-30, -10, -27, T = 3.89, p < .005, unc.), right posterior cingulate cortex (8, -38, 19, T = 3.84, p < .005, unc.), and right postcentral gyrus (56, -16, 30, T = 3.81, p < .005, unc.). However, responses were lower in obese than in lean subjects in the left superior frontal gyrus (-24, 49, 4, T = 3.95, p < .005, unc.). Obese patients showed elevated functional responses to appetizing vs. bland food viewing compared with controls specifically in the right caudate nucleus, whereas they had lowered functional responses in the left insula, lateral frontal cortex, superior parietal lobule, right orbitofrontal cortex and superior temporal gyrus. The evaluation of functional connectivity of the caudate nucleus revealed that obese patients showed significantly larger coupling between right caudate nucleus and right basolateral amygdala (33 -5 -16, T = 3.92, p < .005, unc.), primary somatosensory cortex (39, -13, 32, T = 3.63, p < .005) and posterior insula (30, 14, 18, T = 3.47, p < .005) than lean control subjects. This abnormal connectivity was specific to obesity, since no task-dependent changes in connectivity while viewing appetizing vs. bland foods were observed in the whole study group.
Conclusion: We found that obese individuals had increased hemodynamic responses in the caudate while viewing appetizing vs. bland foods, and increased amygdala responses to both appetizing and bland foods. Moreover, while viewing appetizing vs. bland foods the functional connectivity of the caudate nucleus and amygdala was increased in the obese vs. lean individuals. Conversely, insular cortex showed elevated responses to appetizing vs. bland foods in lean vs. obese individuals. These data show that adiposity is associated with caudate nucleus's elevated baseline activity, responses to appetizing foods as well as functional connectivity with amygdala and insula while viewing appetizing and bland foods. The elevated amygdala responses to foods and increased amygdalo-striatal connectivity and high tonic GMR in obese patients could be the critical mechanism which would explain overeating in obesity.

MRI-measured cerebral microbleeds and their relation to cognitive functioning and cerebral activity in patients with longstanding type 1 diabetes mellitus

E. van Duinkerken[1,2], M.P. Wattjes[3], F.J. Snoek[2], E.H. Serné[4], M. Klein[2], C.J. Stam[5], R.G. IJzerman[1], F. Barkhof[3], M. Diamant[1];
[1]Diabetes Centre / Department of Internal Medicine, [2]Department of Medical Psychology, [3]Department of Radiology, [4]Department of Internal Medicine, [5]Department of Clinical Neurophysiology / MEG Centre, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Only recently an increased occurrence of cerebral microbleeds (CMB), a magnetic resonance imaging (MRI) marker of vascular fragility, was reported in type 2 diabetic patients, in particular in those with proliferative diabetic retinopathy (DRP), relative to non-diabetic subjects. Here, we explored the relationship of CMBs, cognitive functions and functional brain connectivity, using MRI, neuropsychological assessment and magnetoencephalography (MEG), respectively, in a sample of patients with type 1 diabetes (T1DM) with and without microangiopathy and controls.
Materials and methods: Forty-eight T1DM patients with microangiopathy, 43 T1DM patients without microangiopathy and 42 healthy controls underwent MRI imaging using susceptibility-weighted imaging (SWI) to detect CMBs and neuropsychological assessment to measure cognitive performance. Blood was drawn and cortical communication was recorded by MEG.
Results: Nineteen participants (14.3%) showed one or more CMBs on SWI, of whom 11 had T1DM with microangiopathy (9.0%), 3 were T1DM patients without microangiopathy (2.3%) and 4 were controls (3.0%). Those with CMBs were older (45.8 vs 39.3 P = 0.007). CMBs were mainly located in the

temporal and frontal areas. There were no statistically significant more CBMs in the whole diabetes group compared to controls (P > 0.05), however, a significant linear trend across the 3 groups was observed (P = 0.035). Adjustment for age, gender, hypertension and depressive symptoms yielded significantly more CMBs in T1DM participants with microangiopathy as compared to T1DM patients without microangiopathy and healthy controls (both P > 0.05). Adjusting for either diabetes duration or diabetes age-of-onset, did not change the results. Interestingly, individuals with CMBs did not show cognitive impairments (P > 0.05), but demonstrated lower cortical communication in the lower alpha-band (8 - 10 Hz) compared to all individuals without CMBs (P < 0.05). Per group analyses yielded the same pattern of changes in cerebral communication, albeit in different frequency bands, with preserved cognitive functions. In T1DM patients the presence of CMBs was significantly correlated with later-onset of diabetes (P < 0.05).
Conclusion: Taking into account the relatively small number of patients affected, the results indicate that CMBs are more prevalent in T1DM patients with microangiopathy and are related with changes in cerebral communication. CMB presence was not associated with impaired cognitive functioning, but related to older age at diabetes onset. We hypothesize that the observed changes in cortical communication may reflect a restructuring of neural networks in order to compensate for structural damage, thus allowing cognitive functions to be temporarily spared. Whether CMBs are a marker of future cognitive decline, and whether these abnormalities are diabetes-specific, remains to be determined in large-scaled longitudinal studies.

Comparison of neuropsychological testing and 99mTc-HMPAO brain SPET findings in patients with diabetes mellitus type 1 and type 2
M. Migra[1], M. Kutlák[1], A. Lacko[2], P. Galajda[1], M. Mokan[1];
[1]1. Internal Clinic, Faculty Hospital in Martin, [2]Internal Clinic, Central Military Hospital, Ružomberok, Slovakia.

Background and aims: Diabetes mellitus is a chronic metabolic disease characterised by macrovascular and microvascular complication. Although the evidence of cognitive deterioration in diabetic individuals is well known, the neuroanatomical substrate of subscribed changes remains uncertain. Evaluate and localise the resting alterations in brain microcirculation and compare them with affected cognitive domains.
Materials and methods: We examined 47 patients, 20 individuals with T1DM (13 men, 7 women), average age 37 ± 12,7 years, 27 individuals with T2DM (14 women, 13 men), average age 60 ± 9,2 years. Diabetic patients were compared with control group composed of 40 non-diabetic age-related individuals. Written consent was obtained from all patients prior the study. Patients performed battery of neuropsychological testing including 9 tasks covering 5 cognitive domains. Individuals underwent 99mTc-HMPAO brain SPET. Vascular and metabolic determinants were recorded. Collected data were analysed using nonparametric statistic methods.
Results: Compared to control group we found in type 1 diabetics changes in working memory, mental flexibility, mental recording, vigilance and information processing (p = 0,01) without significant correlation to gender, age, metabolic compensation or duration of diabetes (p > 0,05). In type 2 diabetes we discovered deterioration of short time memory, mental flexibility, information processing (p < 0,01) correlated with duration of diabetic disease more than 10 years (p = 0,01). Brain SPET revealed hypoperfusion on microcirculatory level in 65 % of T1DM group (thalamus and basal ganglia 30 %, temporal lobe 20 %, parietal lobe 40 %, cerebellum 25 %, occipital lobe 10 %, frontal lobe 10 %). In T2DM cohort was hypoperfusion in 81 % patients (parietal lobe 64 %, temporal lobe 36 %, occipital lobe 27 %, cerebellum 18 %, thalamus and basal ganglia 9 %. In frontal lobe we have seen both hypoperfusion and hyperperfusion in 32%) related to age and duration of diabetes. Comparing the results of neuropsychological testing to brain SPET findings in both diabetic groups we found anatomically equivalent correlation only in verbal memory test, digit span test backwards and Stroop test C.
Conclusion: We confirmed expected cognitive changes in diabetic individuals, which did not correlate with brain SPET findings in all cognitive domains. Therefore we suggest multidimensional patomechanism including changes in perfusion, neurotransmitters and neuronal metabolism.

OP 40 The diabetic patient in the hospital

Mean glucose during ICU admission is related to mortality by a U-shaped curve; implications for clinical care
J.H. DeVries[1], S.E. Siegelaar[1], J. Hermanides[1], H.M. Oudemans-van Straaten[2], P.H.J. van der Voort[2], R.J. Bosman[2], D.F. Zandstra[2];
[1]Internal Medicine, Academic Medical Centre, [2]Intensive Care Medicine, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands.

Background and aims: Reducing hyperglycaemia at the ICU reduces mortality but recently the optimal glucose target range has become unclear. We investigated in which way glucose regulation, defined as mean achieved glucose concentration during admission, is associated with ICU mortality, thereby trying to reconcile the conflicting data from the Leuven and NICE-SUGAR trials.
Materials and methods: We performed a retrospective database cohort study including patients admitted to a 20-bed medical/surgical ICU in a teaching hospital between January 2004 and December 2007. 5983 patients were eligible for analysis after excluding readmissions, patients with a withholding care policy and patients with only one glucose value measured. From this population we randomly selected 2435 patients with a surgical/medical ICU admission ratio of 55/45%, to enable comparison with the Leuven and NICE-SUGAR populations. All patients were treated for hyperglycaemia using a fully computerized tight glucose algorithm targeting for glucose values between 4.0 and 7.0 mmol/l. The cohort was subdivided in deciles and logistic regression analysis was performed adjusted for age, sex, severity of disease and admission duration to assess the odds ratio of ICU mortality per glucose stratum.
Results: A median (IQR) of 12 (8-14) glucose values per admission day per patient was collected. The total population and the random sample were comparable regarding all baseline characteristics. We observed a U-shaped relation between mean glucose and mortality, with high mortality in the lowest and highest glucose-stratum, 21.3% and 27.6% respectively. Mean glucose values <7.0 mmol/l and >9.0 mmol/l were associated with significantly increased ICU mortality compared with the stratum with the lowest mortality (OR 2.06-4.24 and 2.33-6.70 respectively; Figure). Limitations of the study were its retrospective design and possible incomplete correction for severity of disease.
Conclusion: Mean glucose during ICU admission is related to mortality by a U-shaped curve. A 'safe range' of mean glucose regulation might be defined between 7.0 and 9.0 mmol/l. The U-shaped curve may help to explain the increased mortality in the intensively treated group of the NICE-SUGAR study but not the low mortality in the intensively treated groups of the Leuven studies. According to these findings and awaiting further studies we recommend treating hyperglycaemia at the ICU in a moderately intensive way, targeting for mean glucose values between 7.0 and 9.0 mmol/l and avoiding hypoglycaemia.

Accuracy and reliability of continuous glucose monitoring at the ICU; a head to head comparison of two subcutaneous glucose sensors in cardiac surgery patients

S.E. Siegelaar[1], T. Barwari[1], J. Hermanides[1], W. Stooker[2], P.H.J. van der Voort[3], J.H. DeVries[1];
[1]Internal Medicine, Academic Medical Centre, [2]Cardiothoracic Surgery, Onze Lieve Vrouwe Gasthuis, [3]Intensive Care Medicine, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands.

Background and aims: Both hyperglycaemia and hypoglycaemia are common during intensive care unit (ICU) stay and are associated with increased mortality. Continuous glucose monitoring (CGM) is a promising tool to assist glucose control but the accuracy and reliability of these devices in critically ill patients is uncertain. We studied two different CGM devices post-operatively in cardiac surgery patients in an investigator initiated trial.
Materials and methods: Two CGM devices (Guardian RT, Medtronic Minimed; FreeStyle Navigator, Abbott Diabetes Care) were placed subcutaneously in the abdominal area in 60 patients before surgery. Both devices were calibrated simultaneously upon arrival at the ICU after surgery. Further calibrations were performed according to manufacturers' instructions. An arterial blood glucose value was measured with an AccuChek device as a reference value every two hours. Mean absolute difference (MAD) between reference and sensor glucose values was calculated in six 5 minute intervals after the time of the reference glucose, to assess a possible delay for the CGM devices.
Results: In total, 1017 reference glucose values were measured. Of those, 77.8% could be paired with a Guardian and 91.8% with a Navigator glucose value. Missing values indicate technical problems with the device. Median (IQR) MAD was significantly smaller for Navigator compared to Guardian glucose measurements at the first and second interval (0.11 [0.08-0.16] and 0.10 [0.08-0.16] compared to 0.14 [0.11-0.18] and 0.14 [0.11-0.17], p=0.05 and p=0.001, Wilcoxon signed ranks test; figure). The lowest MAD of the Navigator was observed in the second interval, 5-9 minutes after reference glucose. The MAD of the Guardian was lowest after 15-19 minutes. Only for the Guardian there was a significant decrease over time indicating a delay (p=0.01, repeated measures ANOVA). For glucose values ≤6 mmol/l median (IQR) MAD was lower for the Navigator in all intervals, however not significantly (interval 1: Navigator 0.13 [0.10-0.33], Guardian 0.26 [0.17-0.41], p=0.24). The limited number of values ≤6 mmol/l (n=121) could have limited the power of this sub-analysis.
Conclusion: We report that the FreeStyle Navigator CGM system performed better than the Guardian RT in accuracy as well as reliability in post-operative cardiac surgery patients during ICU stay. Remarkably, the MAD of both sensors was quite good as compared to reported data for outpatients. Based on our results we conclude that this device can be used in this group of ICU patients characterized by relatively low disease severity scores and low mortality rates. Whether or not the use of CGM improves glycemic control and mortality has needs further research.

Intensive care unit (ICU) glucose monitoring measured in plasma using mid-infrared spectroscopy

G. Lim[1], C. Calentine[1], J. Gable[1], L. Nosek[2], T. Heise[2];
[1]Optiscan Biomedical Corporation, Hayward, USA, [2]Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany.

Background and aims: There are increasing calls for a highly accurate, automated system to enable tight glycemic control and avoid hypoglycemia in an ICU setting. The OptiScanner (model 5000) is a glucose monitor based on mid-infrared spectroscopy that draws blood samples (120 µl) and measures plasma glucose concentration approximately every 15 min. The goal of this study was to validate the performance of the OptiScanner at different glycemic levels in a healthy diabetic patient population.
Materials and methods: Sixty people (50 males, age 49 (18-65) years, BMI 29.7 (21.4-40.1 kg/m^2)) with type 1 (n=18) or type 2 (n=42) diabetes were connected to an OptiScanner. Their blood glucose concentrations were kept in a euglycemic (75-180 mg/dl), hypoglycemic (180 mg/dl) range by iv administrations of insulin and glucose. Each OptiScanner blood sample was automatically withdrawn from a forearm vein. Blood samples for reference measurements using the YSI 2300 were withdrawn from the same arm within 60 seconds of the OptiScanner draw and analyzed immediately.
Results: The aggregate data points (1155 paired readings between the OptiScanner and the YSI 2300) were within ISO standard, with 98.6% of the glucose values within +/-20% above 75 mg/dL and +/- 15 mg/dl below this value. A Clark Error Grid analysis showed a total of 1139 points (98.6%) in Zone A. Points outside of A exceeded the A zone boundary by an average of 4.3% and a maximum of 26.4%. The total coefficient for variance was 6.4%. The total r^2 was 0.99.
Conclusion: These preliminary results show that the OptiScanner is highly accurate in a healthy diabetic population.

Randomised study of basal bolus insulin therapy in the inpatient management of patients with type 2 diabetes undergoing general surgery (RABBIT 2 Surgery)

G.E. Umpierrez[1], D. Smiley[1], S. Jacobs[1], L. Peng[2], A. Temponi[1], C. Newton[1], D. Umpierrez[1], P. Mulligan[1], D. Olson[1], M. Rizzo[3];
[1]Medicine-Division of Endocrinology, Emory University, [2]Department of Biostatistics, Emory University Rollins School of Public Health, [3]Department of Surgery, Emory University, Atlanta, USA.

Background and aims: This randomized multicenter trial compared the efficacy and safety of a basal/bolus regimen to sliding scale regular insulin (SSI)

in non-ICU patients undergoing general surgery. Study outcomes included differences in daily BG levels and a composite of hospital complications including postoperative wound infection, pneumonia, respiratory failure, acute renal failure, and bacteremia.
Materials and methods: A total of 211 patients (age: 58±11 yr, admission BG: 190±92 mg/dl, A1C: 7.72±2.2%, ±SD) with a BG between 140-400 mg/dl and a history of T2DM >3 months were randomized to glargine + glulisine (Gla+Glu, n=104) or SSI (n=107). Total daily dose of Gla+Glu was started at 0.5 U/kg, given half as glargine once daily and half as glulisine before meals. SSI was given 4 times/day for BG >140 mg/dl.
Results: The mean daily BG level after the 1st day of Gla+Glu vs. SSI was 145±32 mg/dl and 172±47 mg/dl, respectively, p<0.01. The percentages of BG readings <140 mg/dl were higher in Gla+Glu than SSI (53±30% vs 31±28%, p<0.001). We observed significant difference between groups in the frequency of the composite outcome (24.3% and 8.6% in the SSI and Gla+Glu, respectively; P=0.003). There were no differences in mortality (1% vs 1%); however, there were reductions with Gla+Glu as compared with SSI in wound infection (2.9% vs 10.3%), pneumonia (0% vs 2.8%), and acute renal failure (3.8% vs 10.3%), p=0.05, 0.24, 0.10. Compared to SSRI group, Gla+Glu reduced the number of post-surgical ICU admissions (19.6% vs 12.5%, p=0.159) and ICU length of stay (3.2±2 vs 1.2±0.6 days, p=0.003). A BG <70 mg/dl was reported in 23.1% of patients (1.9 % of BG readings) in the Gla+Glu and in 4.7% (0.3% of BG readings) in the SSI group, p<0.001; but only 3.8% of patients in the Gla+Glu and 0% in SSI had a BG <40 mg/dl (p=0.057).
Conclusion: In summary, treatment with glargine once daily plus glulisine before meals improved glycemic control and reduced hospital complications compared to SSI in general surgery patients with T2DM. Our study indicates that basal/bolus insulin regimen is preferable to SSI in the hospital management of general surgery patients with T2DM. NCT00596687.

OP 41 Deregulation of fatty acid handling, obesity and diabetes

233

Effect of different dietary fat quantity and quality on skeletal muscle fatty acid handling in subjects with the metabolic syndrome
A. Jans[1], A.M.J. van Hees[1], I.M.F. Gjelstad[2], A.C. Tierney[3], U. Risérus[4], C.A. Drevon[2], H.M. Roche[3], E.E. Blaak[1];
[1]Human Biology, Maastricht University, Netherlands, [2]Department of Nutrition, University of Oslo, Norway, [3]Nutrigenomics Research Group, University College Dublin, Ireland, [4]Department of Public Health and Caring Sciences, Uppsala University, Sweden.

Background and aims: Insulin resistance is characterized by disturbances in lipid metabolism and increased fat storage in 'non-adipose tissues' like skeletal muscle (SM). The aim of this study was to investigate whether SM gene expression and the lipid content and the fatty acid (FA) profile of the SM lipids are affected by diets with different fat quantity and quality in subjects with the metabolic syndrome (MetS, NCEP criteria).
Materials and methods: 84 subjects (age 57.3±0.9y, BMI 30.9±0.4kg/m2, 42men/42women) were randomly assigned to one of four isoenergetic diets: high-SFA (HSFA); high-MUFA (HMUFA) and two low-fat, high-complex carbohydrate (LFHCC) diets, supplemented with 1.24 g/day of long chain n-3 PUFA (LCn-3) or control for 12 weeks. Insulin sensitivity (SI) was determined by a insulin modified intravenous glucose tolerance test. SM biopsies were taken before and after the intervention to determine expression of genes involved in lipid metabolism. In a subgroup (n=25, all men) muscle TAG, DAG, free FA (FFA), and phospholipid content, their fractional synthetic rate (FSR) as well as lipid composition were determined. The people in the subgroup consumed (before and after dietary intervention) a high-fat mixed meal (2.6MJ, 61E% fat) with 200 mg [U-13C]-palmitate added. Muscle biopsies were taken before and four hours after the meal. The FSR per lipid fraction was calculated by dividing the change in 13C-enrichment (at 4h postprandial minus baseline) in each fraction by the change in 13C-enrichment in the precursor pool (FFA). The study protocol was approved by the local Medical Ethical Committee of the Maastricht University.
Results: Expression of genes involved in lipogenesis (SREBP1c, SREBP2, ChREBP and ACC2) were downregulated after 12-weeks on HMUFA (mean fold change (FC) of -1.3) and on LFHCC LCn-3 (mean FC -1.7) in insulin resistant (IR) subjects (below the median of SI), whereas insulin sensitive (IS) subjects showed the opposite effect (mean FC +1.6 at both diets). HMUFA diet caused reduced DAG content (paired t-test p=0.027) and tended to decrease the FSR in TAG (p=0.055) and DAG (p=0.066). LFHCC LCn-3 diet reduced the muscle TAG content (p=0.032) and tended to increase percentage saturation of DAG (p=0.064).
Conclusion: Both HMUFA and LFHCC LCn-3 promoted a reduction of lipogenic genes in IR subjects with the MetS. In a subgroup HMUFA and LFHCC LCn-3 reduced DAG or TAG content, respectively, suggesting that these diets may reduce muscle fat accumulation by affecting the balance between fat storage and oxidation.

Adipokines promote lipotoxic effects of low levels of palmitic acid but not oleic acid by reducing fatty acid oxidation and increasing diacylglycerol
A. Taube[1], B. Platzbecker[1], A. Schober[1], G. van Echten-Deckert[2], M. Bosma[3], J. Weiss[1], K. Jeruschke[1], K. Eckardt[1], J. Eckel[1];
[1]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, [2]Kekulé-Institute LIMES Membrane Biology and Lipid Biochemistry, University of Bonn, Germany, [3]Department of Human Biology, Maastricht University, Netherlands.

Background and aims: Skeletal muscle insulin resistance is an early defect in the pathogenesis of type 2 diabetes mellitus. Numerous studies have shown that elevated plasma free fatty acid (FA) levels as well as intramyocellular lipid accumulation are positively correlated with the incidence of insulin resistance. Furthermore, it is accepted that adipose tissue functions as a secretory organ releasing various adipokines. Aim of this study was to investigate combined effects of adipokines with physiological concentrations of free FA on human skeletal muscle metabolism. Furthermore, possible differences of saturated and unsaturated FA were to be analysed.

Materials and methods: Differentiated primary human skeletal muscle cells (SkMC) were incubated with adipocyte-conditioned media (CM) for 24 h, while oleic acid (OA, 100 µmol/l) or palmitic acid (PA) were added for the final 18 h of incubation. Subsequently, SkMC were lysed for Western Blot analysis, incubated with ^{14}C-FA for FA oxidation, fixed for microscopic examination, or analysed using thin layer chromatography (TLC).
Results: Incubation of SkMC with CM increased the expression of FA transport protein CD36 (2-fold, n=3), while isolated adipokines failed to produce the same effect. Electron microscopic examination showed profound accumulation of lipid droplets after incubation with OA and CM, while there were no lipid droplets observed after treatment with PA alone or combined with CM. However, mitochondrial morphology was noticeably altered after treatment with PA. Analysis of the lipid droplet coating protein ADRP revealed a significantly increased expression after incubation with OA and CM (2-fold, n=6). FA oxidation was found to be reduced after incubation with PA and CM (by 72%), while incubation with CM (34%), OA (23%), and OA in combination with CM (33%, n≥5) caused a more moderate effect. Additionally, treatment of SkMC with a higher FA concentration (300 µmol/l) yielded a more severe reduction of FA oxidation by ~90% after treatment with PA and CM. TLC analysis revealed a significantly increased diacylglycerol (DAG) content (3-fold, n≥3) after incubation with PA and CM.
Conclusion: The results of this study indicate that physiological levels of FA, which are described to not affect SkMC metabolism, have deleterious effects in combination with adipokines. Hence, it may be speculated that adipokines rather than FA may play a more crucial role in mediating insulin resistance, since they not only increase FA uptake but also seem to interfere with FA metabolism. Furthermore, these results support the notion that saturated FA like PA are more detrimental than unsaturated FA like OA. While OA seems to increase the potential of the cell to store excess lipids in lipid droplets by increasing the expression of ADRP, PA seems to impair mitochondrial integrity and in combination with adipokines leads to incomplete FA oxidation and concurrent accumulation of DAG. Thus it may be assumed that already at an early stage of weight gain, when lipolysis has not yet contributed to increased plasma free FA levels, there might be lipotoxic damage to skeletal muscle cells.

235

Splanchnic balance of free fatty acids, endocannabinoids and lipids in subjects with NAFLD

A. Kotronen[1], J. Westerbacka[1], B.A. Fielding[2], J. Wahren[3], L. Hodson[2], T. Seppänen-Laakso[4], T. Suortti[4], J. Arola[1], R. Hultcrantz[3], S. Castillo[4], K.N. Frayn[2], M. Oresic[4], H. Yki-Järvinen[1];
[1]University of Helsinki, Finland, [2]University of Oxford, United Kingdom, [3]Karolinska Hospital, Stockholm, Sweden, [4]VTT Technical Research Centre of Finland, Espoo, Finland.

Background and aims: Animal studies suggest that endocannabinoids could contribute to the development of non-alcoholic fatty liver disease (NAFLD). In addition, NAFLD has shown to be associated with multiple changes in lipid concentrations in liver biopsies. There are no data on splanchnic free fatty acid, glycerol, ketone body, endocannabinoid and lipid fluxes *in vivo* in subjects with NAFLD.
Materials and methods: We performed hepatic venous catheterization studies in combination with [$^2H_2$]palmitate infusion in the fasting state and during a low-dose insulin infusion (0.5 mU/kg min) in nine subjects with various degrees of hepatic steatosis as determined using liver biopsy. Splanchnic balance of endocannabinoids and individual lipids was determined using Ultra Performance Liquid Chromatography coupled to mass spectrometry.
Results: Splanchnic free fatty acid (FFA) extraction during the euglycemic hyperinsulinemia correlated with liver fat content (r=0.75, p=0.05). Concentrations of the endocannabinoid anandamide were higher in arterialized (91±33 µmol/l basally) than in hepatic venous (51±19 µmol/l, p<0.05) plasma. Fasting arterial (r=0.72, p=0.031) and hepatic venous (r=0.70, p=0.037) concentrations of anandamide were positively related to liver fat content. Analysis of fluxes of 85 different triglycerides showed that the fatty liver overproduces saturated triglycerides. In the plasma FFA fraction in the basal state, the relative amounts of palmitoleate and linoleate were lower and those of stearate and oleate higher in the hepatic vein than in the artery. Absolute concentrations of all non-triglyceride lipids were comparable in arterialized venous plasma and the hepatic vein both in the basal and insulin-stimulated states.
Conclusion: FFA extraction during hyperinsulinemia correlates with liver fat content, consistent with data showing defects in insulin action on lipolysis to contribute to liver fat. The human fatty liver takes up anandamide and overproduces triacylglycerols containing saturated fatty acids, which might reflect increased *de novo* lipogenesis.

Fatty acid class influences spillover from chylomicrons into plasma nonesterified fatty acids

R.H. Nelson, A. Smailovic, D. Vlazny, J.M. Miles;
Endocrinology, Mayo Clinic, Rochester, USA.

Background and aims: The mechanism by which diets high in polyunsaturated fatty acids (PUFA) reduce cardiovascular risk is not known. Lipoprotein lipase (LPL) mediates dietary fat storage in adipose tissue via its action on chylomicron triglycerides, but a portion of LPL-generated fatty acids are released directly into the plasma nonesterified fatty acid (NEFA) pool via a process known as spillover. The present study was undertaken to determine whether there are differences in spillover among different classes of fatty acids.
Materials and methods: Twelve lean, healthy adults were studied after a 5 day controlled diet and an overnight fast. Volunteers consumed ~15 mL of a liquid meal, consisting of a commercial dietary supplement and [1-^{13}C] tripalmitin, [1-^{13}C] triolein and [9,10-^{3}H] trilinolein, every 15 minutes for 6 hours. [1-^{14}C] palmitate, [U-^{13}C] oleate and [U-^{13}C] linoleate were infused intravenously for 2 h. Blood samples were taken for NEFA concentrations, tracer enrichment and specific activity, as well as chylomicron and total triglyceride concentration. Systemic rate of appearance (R_a) and spillover were calculated for each fatty acid using steady state assumptions.
Results: Total NEFA concentrations were 114±11 µmol/L during meal absorption. Plasma oleate concentration was significantly higher than palmitate or linoleate concentrations (41±5 vs 23±3 and 29±3 µmol/L, respectively; p<0.05 for both). The R_a of palmitate was significantly lower than the R_a of either linoleate or oleate (0.4±0.03 vs 0.8±0.07 and 0.8±0.06 µmol/kg/min, respectively, both p < 0.001). Clearance of linoleate was higher than that of either palmitate or oleate (32±3 vs 21±3 and 22±2 mL/kg/min, respectively; p < 0.03 for both). Fractional spillover among the 3 groups was 40±4% v 38±3% v 23±2% for palmitate, oleate and linoleate respectively. The difference between linoleate compared to palmitate and oleate was significant (p<0.01 for both comparisons). There was no difference between palmitate and oleate spillover.
Conclusion: These data show a significant difference in spillover of chylomicron linoleate during meal absorption in normal subjects compared to the other two most abundant dietary fatty acids. The low spillover of linoleate indicates comparatively efficient storage of this fatty acid and thus less availability for ectopic fat accumulation in tissues such as liver and skeletal muscle. The relationship between this finding and the apparent reduction in cardiovascular risk associated with PUFA-enriched diets will require further study.

Resistin and adipocyte fatty acid binding protein are linked in type 2 diabetes mellitus and atherosclerosis

C. Höbaus[1], M. Grujicic[1], M. Ursli[1], T. Hoertenhuber[1], N. Reinprecht[1], F. Höllerl[1,2], G. Schernthaner[2], R. Koppensteiner[1], G.-H. Schernthaner[1]; [1]Angiology, Medical University of Vienna, [2]Medicine I, Rudolfstiftung, Vienna, Austria.

Background and aims: Systemic atherosclerosis is the co-morbidity of type 2 diabetes mellitus (T2D). Patients with T2D have increased body weight and adipokine production. The adipokines resistin and adipocyte fatty acid binding protein (AFABP) have each been linked to T2D and atherosclerosis. Recently, a direct influence of resistin on AFABP has been demonstrated in cell culture of human endothelial cells, whereas respective experiments in knockout mice failed. We investigated the interrelationship of resistin and AFAB in a cohort study of human individuals.
Materials and methods: Resistin and AFABP serum levels were investigated in 168 patients (61 female, 107 male) with systemic atherosclerosis. All patients suffered from peripheral arterial disease (PAD); 76 patients showed additional coronary or cerebral artery disease. Oral glucose tolerance tests (oGTT) were performed in all patients. Resistin and AFABP were obtained by commercially available ELISA (BioVendor, Modrice, Czech Republic). Inter-assay coefficient of variation (CV) and intra-assay CV were 7.8% and 4.8% for resistin and 6.5%, and 2.9% for AFABP. Students' unpaired t-test, univariate and multivariate regression modeling were applied as appropriate. Skewed data were lg10 transformed to render the distribution normal for parametric tests. Normal data are given as mean±STD, non-parametric data as median (25%;75%). In multivariate analysis, change of beta (D-beta) over 10%, were considered as confounding.
Results: According to oGTT, we had 51 subjects with normal glucose metabolism (NGM), 35 subjects with pre-diabetes (PRED, impaired fasting glucose/glucose tolerance), and 82 subjects with overt T2D. Resistin levels did not differ (NGM vs PRED vs T2D 6.5±1.7 vs 7.02±2.9 vs 7.26±2.5 ng/ml; p=0.195). AFABP levels were significantly higher in diabetes (NGM vs PRED vs T2D 29 (16;39) vs 30 (20;41) vs 33 (23;45) ng/ml; p=0.035). By univariate regression resistin was associated with AFABP in all patients (beta=0.308; p<0.001). Subgroup analysis revealed that the association was based on T2D (beta=0.392; p<0.001). Since recent papers have suggested an association between diabetes, hypertension and resistin in mouse models, data of the T2D subgroup were tested for confounding by multivariate modeling. Linear regression revealed that the effect of resistin on AFABP is not affected by the subjects' blood pressure (systolic D-beta=1%; diastolic D-beta=2%), but is attenuated with increasing number of anti-hypertensive medication taken by the patient (D-beta=11%). Vice versa, alternative linear regression models showed that the association of AFABP on resistin is not affected by the subjects' blood pressure (systolic D-beta=1%; diastolic D-beta=0%) or hypertension medication (D-beta=1%). Furthermore, this association of resistin on AFABP or AFABP on resistin was not attenuated by body mass index in multivariate models (D-beta=1% and D-beta=4%). The severity of atherosclerosis showed no effect on resistin and AFABP levels.
Conclusion: This is the first study to demonstrate an association of the adipokines resistin and AFABP in patients with systemic atherosclerosis. This association was due to the existence of diabetes, but not pre-diabetes. Whether hypertension is interrelated with resistin and AFAB in patients with or without diabetes needs to be investigated.

Asymmetric dimethylarginine does not contribute to endothelial dysfunction in subjects with abnormalities of glucose regulation

D. Lucchesi[1], L. Pucci[1], R.M. Bruno[2], L. Ghiadoni[2], E. Storti[1], E. Russo[1], C. Bianchi[1], G.A. Daniele[1], S. Taddei[2], G. Penno[1], S. Del Prato[1], M.C. Stuhlinger[3], R. Miccoli[1];
[1]Endocrinology and Metabolism, [2]Internal Medicine, University of Pisa and Azienda Universitaria Ospedaliera Pisana, Pisa, Italy, [3]Division of Cardiology, University of Innsbruck, Austria.

Background and aims: Asymmetric dimethylarginine (ADMA), an endogenous inhibitor of endothelial nitric oxide synthase (eNOS), has been associated with endothelial dysfunction and atherosclerosis. Increased plasma levels of ADMA have been described in diabetic subjects with nephropathy or cardiovascular disease. Studies assessing ADMA levels in people with uncomplicated type 1 or type 2 diabetes report conflicting results.
Materials and methods: Circulating levels of ADMA, SDMA (symmetrical dimethylarginine) and L-arginine (L-arg) together with brachial artery endothelium-dependent flow-mediated dilation (FMD) and endothelium-independent dilation by 25 μg sublingual glyceryl trinitrate (GTN) were evaluated in 26 subjects with normal glucose tolerance (NGT), 34 with pre-diabetes (IFG or IGT, pre-DM) and 18 newly diagnosed type 2 diabetics (newT2DM) identified through OGTT. Plasma concentrations of ADMA, SDMA and L-arg were determined simultaneously by high-performance liquid chromatography. FMD and GTN were assessed by high-resolution ultrasound and computerized edge detection system.
Results: Groups showed similar distribution for gender, smoking habits, BMI, waist circumference, dBP, total and LDL cholesterol, apoA1 and apoB, fibrinogen, and fasting insulin. Namely, there were no differences in eGFR and cystatin C. Age (55±5, 53±8 vs 48±9 years, p=0.01), fasting and post-load OGTT glucose, glucose area under the OGTT curve (AUCgluc), HbA1c (6.0±0.4, 6.5±0.6 vs 5.5±0.4%, p<0.0001) and triglycerides were higher in pre-DM and newT2DM than in NGT; HDL cholesterol was lower. In pre-DM, sBP (127±13) was in between NGT (118±15) and newT2DM (137±15 mmHg, p=0.0005). GTN decreased (Δ% 9.9±3.4, 8.8±3.3 and 7.4±3.9, m±sd; p=0.081) with significant differences between NGT and newT2DM (p=0.025). FMD was lower in newT2DM (Δ% 4.4±3.3, m±sd) and in pre-DM (Δ% 6.0±2.8) compared with NGT (Δ% 7.9±3.6, p=0.0017). L-arg levels were similar in NGT (97.5±20.0) and pre-DM (97.1±20.6), lower in newT2DM (81.2±18.9 μmol/l, p=0.015). ADMA progressively reduced from NGT (1.33±0.96 μmol/l) to pre-DM (1.02±0.79 μmol/l, p=0.14 vs NGT) and newT2DM (0.72±0.53 μmol/l, p=0.017 vs NGT; ANOVA, p=0.05). SDMA was similar in NGT (1.78±0.74) and pre-DM (1.56±1.02, p=0.31), reduced in newT2DM (0.97±0.35 μmol/l, p=0.002 vs NGT, p=0.02 vs pre-DM; ANOVA, p=0.006). No association was observed between ADMA (or SDMA) and eGFR or cystatin C. No correlation emerged between ADMA and FMD (r=0.14, p=0.23) with a weak one between ADMA e GTN (r=0.29, p=0.014). By multiple regression, AUCgluc (p=0.002) and sBP (p=0.047), but not ADMA were inversely related with FMD. AUCgluc, inversely, (p=0.024) and ADMA (0.044) correlated with GTN.
Conclusion: We suggest that uncomplicated newT2DM and subjects with pre-DM have lower circulating ADMA than nondiabetic control subjects, in presence of impaired endothelium-dependent flow-mediated dilation. ADMA levels are not related to endothelial function. In these subjects with early abnormalities of glucose regulation, endothelial dysfunction seems not a result of eNOS inhibition by ADMA.

239

Vascular inflammation stratified by C-reactive protein and LDL-cholesterol levels: analysis with ^{18}F-Fluorodeoxyglucose positron emission tomography

H.Y. Choi, J.H. Kim, M.J. Cho, Y.J. Kim, C.R. Eun, S.Y. Yang, H.J. Yoo, H.Y. Kim, J.A. Seo, S.G. Kim, N. Kim, S.H. Baik, D.S. Choi, K.M. Choi; Endocrinology and Metabolism, Korea University College of Medicine, Seoul, Republic of Korea.

Background and aims: ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography (PET) is a promising imaging technique for the assessment of vascular inflammation within atherosclerotic plaques. Inflammatory biomarkers, such as high sensitivity C-reactive protein (hsCRP), have been suggested as independent predictors of cardiovascular events that add prognostic information beyond conventional risk factors. Recently, the justification for the use of statins in primary prevention: an intervention trial evaluating rosuvastatin (*JUPITER*) study has demonstrated that rosuvastatin significantly reduces the incidence of major cardiovascular events in asymptomatic individuals with low LDL-C levels, but increased hsCRP levels, a population that is currently not recommended to receive statin therapy.
Materials and methods: We examined vascular inflammation, represented as the target-to-background ratio (TBR) measured using FDG-PET scans in 120 healthy subjects without history of cardiovascular diseases, who had been stratified into four groups according to hsCRP *(cut-point, 2mg/L)* and low-density lipoprotein cholesterol (LDL-C) levels *(cut-point, 130mg/dL)*. We also determined the correlation between circulating levels of other emerging inflammatory markers, such as lipoprotein-associated phospholipase A_2 (Lp-PLA_2), monocyte chemoattractant protein-1 (MCP-1), and vascular inflammation assessed by FDG-PET. Lastly, we compared the factors which determine TBR and carotid intima-media thickness (IMT).

Results: Maximum TBR levels of the high hsCRP, low LDL-C group were significantly higher than those of the low hsCRP, low LDL-C or low hsCRP, high LDL-C group, even though there were no significant differences in IMT. TBR values were associated with various cardiovascular risk factors, including hsCRP, which had the strongest positive correlation with TBR. However, Lp-PLA_2 or MCP-1 levels were not independently associated with TBR values. Multiple stepwise regression analyses showed that hsCRP and diastolic blood pressure were independent decisive factors for maximum TBR, whereas age, diastolic blood pressure, and LDL-C were factors which determined the maximum IMT.
Conclusion: Vascular inflammation measured using FDG-PET was increased in healthy individuals without hyperlipidemia, but with elevated hsCRP.

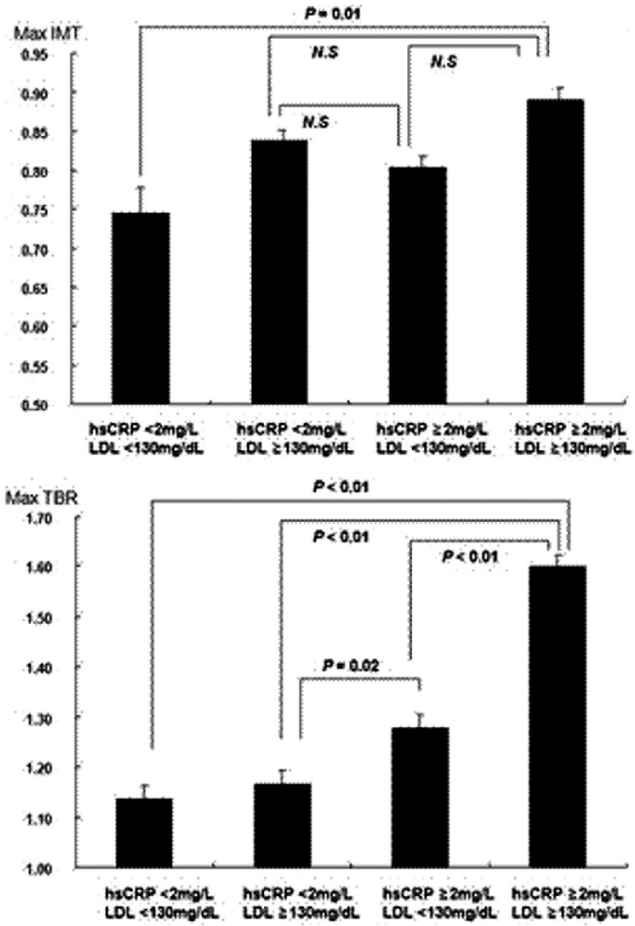

Figure 1. Maximum intima-media thickness (IMT) (A) and maximum target-to-background ratios (TBR) (B) by stratified groups according to high sensitivity C-reactive protein (hsCRP) and low-density lipoprotein cholesterol (LDL-C) levels. P-value represents pair-wise comparison based on Bonferroni's multiple comparison procedure under analysis of covariance (ANCOVA) adjusted for age, gender and BMI. *N.S*, non-significant.

240

High serum LPS-activity is associated with features of the metabolic syndrome in patients with type 1 diabetes

M. Nymark[1,2], C. Forsblom[1,2], P.-H. Groop[1,2], M. Lehto[1,2], on behalf of the FinnDiane Study Group;
[1]FinnDiane, Folkhälsan Insitute of Genetics, [2]Department of Medicine, Division of Nephrology, Helsinki, Finland.

Background and aims: Long duration of diabetes, poor glycemic control and the metabolic syndrome (MetS) increase the risk for diabetic complications (retinopathy, neuropathy and nephropathy). We have recently shown that elevated serum levels of bacterial endotoxins are associated with the development of diabetic kidney disease in Finnish Type 1 diabetic (T1D) patients. In addition to kidney failure, lipopolysaccharide (LPS) infusion in human or in mice induces also insulin resistance, fasting hyperglycemia, and obesity, which all are features of the MetS. In the present study, we wanted to investigate whether serum LPS-activity is associated with MetS in T1D patients with normal albumin excretion.
Materials and methods: Serum LPS activity was analysed in 624 T1D patients and 220 nondiabetic control subjects (Limulus amoebocyte lysate chromogenic end point assay, Hycult Biotechnology). T1D patients were divided into quartiles according to their LPS activity. MetS was assessed according to National Cholesterol Education Program (NCEP) criteria which included waist circumference, triglycerides, HDL-cholesterol, and blood pressure or antihypertensive medication. All patients fulfilled the criteria for hyperglycemia. Three out of five criteria were required for the diagnosis of MetS. A metabolic score (1-5) was calculated based on the number of criteria each patient fulfilled. Data is presented as mean (standard deviation) or median [inter quartile range] as appropriate.
Results: LPS was significantly higher in patients with T1D than healthy controls [57 (50-69) vs. 53 (39-68), p≤0.001]. In T1D patients, comparison was made between the highest (q4) and lowest (q1) LPS quartiles. Patients in q4 had a higher HbA_{1c}, BMI, waist, triglycerides, cholesterol, diastolic blood pressure and lower HDL-cholesterol and insulin sensitivity (eGDR) compared to patients in q1. The overall frequency of MetS was 28% among all T1D patients. Patients belonging to the highest LPS quartile q4 had significantly higher frequency of MetS compared to patients in q1 (Table 1).
Conclusion: In the present study, we show that about one third of T1D patients with normal albumin excretion fullfill the criteria for MetS. Features of the MetS are more often found in T1D patients with high serum LPS-activity. These results indicate that Gram-negative bacterial infections could also play a significant role in the development of MetS. We believe that MetS patients with elevated levels of bacterial endotoxins may carry the highest risk for the development of not only micro- but also macrovascular complications.

Dapagliflozin vs glipizide in patients with type 2 diabetes mellitus inadequately controlled on metformin: 52-week results of a double-blind, randomised, controlled trial

M. Nauck[1], S. Del Prato[2], K. Rohwedder[3], M. Elze[4], S. Parikh[5];
[1]Diabetes Centre, Bad Lauterberg, Germany, [2]University of Pisa, Italy, [3]AstraZeneca, Wedel, Germany, [4]ClinResearch, Koeln, Germany, [5]AstraZeneca, Wilmington, USA.

Background and aims: Glipizide (GLIP) is commonly used as an add-on to metformin (MET), but is associated with weight gain and hypoglycaemia. Dapagliflozin (DAPA) is a selective inhibitor of sodium-glucose cotransporter 2 that inhibits renal glucose reabsorption in an insulin-independent manner. DAPA is a potential therapy to reduce hyperglycaemia in T2DM, and has been associated with weight loss. We tested the efficacy, safety and tolerability of DAPA vs GLIP as add-on to MET in patients with T2DM.
Materials and methods: This randomized, double-blind, active-controlled, parallel-group, multicentre trial (D1690C00004) included patients with T2DM inadequately controlled with oral antidiabetic drugs (OADs) including MET (HbA_{1c} 6.5-10.0%). Prior to randomization, as needed, OADs other than MET were discontinued and MET dose was up-titrated to the nearest of 1500, 2000, or 2500 mg/day, before an 8-week (wk) stabilization period. After a 2-wk placebo lead-in, patients (≥18 years) were randomized to DAPA (n=406, starting 2.5 mg/d) or GLIP (n=408, starting 5 mg/d) added to open-label MET for 52 wk. For the first 18-wk study drugs were up-titrated (GLIP to ≤20 mg/d; DAPA to ≤10 mg/d) until fasting plasma glucose <6.1 mmol/L or to the max tolerated dose. The dose at the end of titration was maintained for a further 34 wk. Down-titration was allowed at any point in cases of recurrent hypoglycaemia. Primary endpoint was change from baseline in HbA_{1c} at 52 wk, tested for non-inferiority of DAPA vs GLIP with a predefined margin of 0.35%. Secondary endpoints included change in body weight and number of subjects reporting hypoglycaemic episodes. There was no preplanned statistical analysis for other adverse events (AEs).
Results: Mean baseline HbA_{1c} was 7.72%. At the end of the titration period, 86.9% of DAPA and 72.5% of GLIP patients were taking max doses. Adjusted mean changes from baseline in HbA_{1c} at 52 wk were -0.52% (95% CI -0.60, -0.44) for DAPA and -0.52% (95% CI -0.60, -0.44) for GLIP (difference [95% CI] = 0.00 [-0.11, 0.11]), confirming non-inferiority. DAPA led to weight loss (change from baseline at 52 wk -3.2 kg) vs weight gain (1.4 kg) with GLIP (difference [95% CI] = -4.7 kg [-5.1, -4.2]; p<0.0001). Significantly more patients experienced weight loss of ≥5% from baseline with DAPA (33.3%) vs GLIP (2.5%) (p<0.0001). There were reductions in systolic and diastolic blood pressure (nominal p<0.0001) and improvement in HDL (nominal p<0.0001) in DAPA vs GLIP. More patients had hypoglycaemic episodes with GLIP (40.8%) vs DAPA (3.5%) (p<0.0001). Overall AEs were similar across groups. Serious AEs were 8.6% in DAPA and 11.3% in GLIP. Actively solicited events suggestive of urinary tract infection (UTI) were 10.8% and 6.4% for DAPA vs GLIP. Actively solicited events suggestive of genital infection (GI) were 12.3% (5.3% male, 21.1% female) and 2.7% (0.4% male, 5.4% female) for DAPA vs GLIP. One UTI led to discontinuation in each of the DAPA and GLIP arms. Three cases of GI led to discontinuation in the DAPA arm.
Conclusion: In T2DM inadequately controlled with OADs including MET, the addition of DAPA was non-inferior to GLIP in improving HbA_{1c} at 52 wk, resulted in significant weight loss and significantly fewer hypoglycaemic episodes vs GLIP, and was generally well tolerated, with a tendency to more UTIs and GIs.

MK-0941, a novel glucokinase activator (GKA), lowers HbA_{1c} in type 2 diabetes (T2DM) but lacks glycaemic durability

G.E. Meininger, Y. Shentu, Y. Chen, Q. Yu, D. Sheng, B.J. Musser, M. Alba, B.B. Zhang, E.M. Migoya, J. Ehrhart, K.D. Kaufman, B.J. Goldstein;
Merck, Rahway, USA.

Background and aims: GKAs are allosteric activators of the GK enzyme that bind to the same region as naturally-occurring GK activating mutations in humans. GKAs are being developed as novel potential treatments for patients (pts) with T2DM. Preclinical studies with the GKA MK-0941 showed robust glucose-lowering effects both acutely and chronically (up to 9 mo) in association with hypoglycaemia (Hypo) in fasted and fed non-diabetic animals. MK-0941 was evaluated in Phase (Ph) I studies, including those up to 4 wks in pts with T2DM, as monotherapy, add-on to metformin (MET), and add-on to insulin glargine (IG). In these studies, MK-0941 was generally well-tolerated, with no significant treatment-related effects on ECGs, vital signs, or lab measures, and was shown to have a duration of action of ~4 hrs. On the background of IG, MK-0941 showed robust glucose-lowering, with a reduction in 24-hr weighted mean glucose (WMG) of ~2.7 mmol/L relative to placebo (pbo). These data supported continuing development of MK-0941 with Ph II studies in pts with T2DM.
Materials and methods: MK-0941 was evaluated in 3 randomized, double-blind Ph II trials:
• 007, a 54-wk, pbo-controlled study in 587 pts on ongoing IG therapy (± MET ≥1500 mg/d), comprising an initial 14-wk, dose-ranging (10 - 40 mg TID) period followed by an additional 40-wk period during which all pts were to be up-titrated as tolerated to 40 mg or pbo TID;
• 017, a 6-wk, active-controlled study in 143 pts on going MET (≥1500 mg/d), with patients randomized to MK-0941 (up to 40 mg TID) or glimepiride (GLIM; up to 8 mg QD);
• 018, a 20-wk, pbo-controlled, MK-0941 dose-titration (up to 40 mg TID) study in 68 pts on ongoing IG therapy.
The primary endpoint was change from baseline in HbA_{1c} (007 and 018) or 24-hr WMG (017).
Results: In 007, at Wk 14, all MK-0941 doses studied significantly improved HbA_{1c} and 2-hr postmeal glucose (PMG) vs. pbo, with maximal pbo-subtracted changes from baseline in HbA_{1c} (baseline HbA_{1c} ~9.0%) and 2-hr PMG of -0.8% and -2.1 mmol/L, respectively. No significant effect on FPG was observed at any dose vs. pbo. Unexpectedly, efficacy results up to 30 wks demonstrated a lack of durability in glycaemic control (despite dose up-titration of MK-0941 after Wk 14), a phenomenon not predicted based on earlier studies. MK-0941 was associated with an increased incidence of Hypo relative to pbo that was, in part, managed with down-titration of MK-0941. In 017, 6-wk treatment with MK-0941 or GLIM added to ongoing MET resulted in similar changes in 24-hr WMG from baseline and incidences of Hypo. In 007 and 017, statistically significant increases in serum triglycerides (~15% median percent increase from baseline) and the proportion of pts meeting criteria for predefined limits of change for BP measures were observed. These safety findings were not seen in preclinical or Ph I studies. In 018, change in HbA_{1c} from baseline at Wk 20 was not significantly different between MK-0941 and pbo when added to IG. The incidence of Hypo was numerically higher with MK-0941.
Conclusion: In Ph I studies, MK-0941 showed promise as an investigational agent for T2DM. This expectation was not borne out in 3 longer-term, Ph II studies. It is unknown if the efficacy and safety profiles observed with MK-0941 were compound-specific or mechanism-based. In light of the above, a better understanding of the GK mechanism and its downstream metabolic effects are needed to determine whether GK activation is a viable treatment target.

A selective GPR40 agonist, TAK-875, augments glucose-dependent insulin secretion without affecting glucagon secretion in isolated rat and human islets

H. Yashiro[1], Y. Tsujihata[1], K. Takeuchi[1], M. Hazama[1], P. Rorsman[2];
[1]Pharmaceutical Research Division, Takeda Pharmaceutical Company Limited, Osaka, Japan, [2]The Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom.

Background and aims: GPR40 is a G protein-coupled receptor dominantly expressed in pancreatic β cells, and is involved in free fatty acid-induced insulin secretion. TAK-875 is a GPR40-selective agonist that improves glucose control in type-2 diabetic animal models by stimulation of glucose-dependent insulin secretion. We examined the effects of TAK-875 on insulin and glucagon secretion, and on intracellular Ca^{2+} ($[Ca^{2+}]_i$) in pancreatic β- and α-cells using both human and rat intact islets.
Materials and methods: Rat and human islets were isolated by collagenase digestion. Secreted insulin and glucagon were measured using radioimmunoassay. Gene expression levels were quantified by TaqMan PCR. For $[Ca^{2+}]_i$ measurement, isolated islets were loaded with fluorescent indicator fluo-4-AM and monitored by confocal microscopy during perifusion experiments.
Results: In static incubation, TAK-875 augmented insulin secretion from rat islets at high (16 mmol/l) but not at low (1 mmol/l) glucose. The glucose-de-

pendent insulinotropic action of TAK-875 was also shown in islet perifusion experiment: TAK-875 enhanced both 1st and 2nd phase insulin secretion at high glucose but was without effect at low glucose. In human islets, expression of GPR40 was comparable to that of GLP-1R or ABCC8 (SUR1), and TAK-875 enhanced glucose-dependent insulin secretion to the same extent as GLP-1 in static incubation experiment. In both rat and human islets TAK-875 was without effect on glucagon secretion at both low and high glucose. Measurements of $[Ca^{2+}]_i$ in intact rat and human islets showed that TAK-875 enhanced glucose-induced $[Ca^{2+}]_i$ in β cells. In contrast to β cells, α cells showed oscillatory $[Ca^{2+}]_i$ response at low glucose which was suppressed by high glucose concentration. The addition of TAK-875 at high glucose did not affect α-cell oscillatory $[Ca^{2+}]_i$ in rat islets, whereas it augmented the inhibitory effect of glucose in human islets.
Conclusion: These data indicate that TAK-875 potentiates glucose-dependent insulin secretion via direct stimulation of $[Ca^{2+}]_i$ in β cells of both rat and human islets. TAK-875 does not increase glucagon secretion or $[Ca^{2+}]_i$ in both rat and human α-cells. We conclude that the glucose-lowering action of TAK-875 principally results from its capacity to stimulate insulin secretion. The fact that it only stimulates insulin secretion at elevated glucose levels without affecting glucagon secretion may offer additional advantages by minimizing the risk of hypoglycaemia.

244

ZGN-201 (ZGN), a methionine aminopeptidase 2 (MetAP2) inhibitor, durably eliminates excess body fat in obese mice through regulation of fat metabolism and food intake
T.E. Hughes, A.J. Nichols, J.E. Vath;
Zafgen, Incorporated, Cambridge, USA.

Background and aims: MetAP2 inhibitor treatment reduces body weight (BW), reduces food intake, and increases fat oxidation in obese mice; however the mechanism(s) leading to weight loss have not been elaborated. We evaluated the effects of a 9 month treatment with ZGN on body weight and metabolic parameters in obese mice.
Materials and methods: Age-matched male C57BL/6J mice were maintained on standard chow or a 60% high fat diet for 12 weeks to induce obesity (DIO; mean BW 39.9 g) prior to treatment for 9 months. After matching on the basis of body weight, animals were assigned to either HFD (DIO; n=15 mice) or HFD supplemented with ZGN-201 to provide a daily dose of ~1 mg/kg (ZGN; n=15 mice). A group of lean age-matched chow-fed mice were studied for comparison (CHOW; n=15 mice). Food consumption was assessed every two days for groups of three animals per cage. Body weights were assessed for each animal every other day. Plasma glucose and beta-hydroxybutyrate concentrations were measured by standard colorimetric assays. Insulin was measured by ELISA. Gene expression analysis was performed in liver using quantitative RQ-PCR, and levels were corrected for expression of 18S rRNA.
Results: During the first 4 weeks of treatment with 1 mg/kg ZGN p.o., mice lost all excess BW (loss of 9.4±0.7g vs a gain of 5.0±0.4g for control (DIO) mice, p<0.01), driven by a 30% reduction in food intake during days 3 - 12 of treatment (p< 0.01). Once a BW nadir was reached on day 28 (23% BW loss, p<0.01), food intake returned to a level 13 percent below DIO (0.81g vs. 0.94g/mouse-day, p<0.01) and was stable for the following 8 months, during which time the ZGN treated animals remained weight stable. Following 9 months, BW of ZGN mice were 43% lower than DIO (32.5±0.8 vs 57.1±1.7g, p<0.01). Fasting plasma glucose (6.8±0.4 vs 11.2±0.8 mmol/L, p<0.01) and insulin (34±17 vs 380±34 pmol/L, p<0.01) were reduced by ZGN and plasma β-hydroxybutyrate was increased (1.5±0.1 vs 1.0±0.1 mEq/L, p<0.05) relative to DIO, a consistent feature of MetAP2 treatment. Gene expression analysis revealed a down-regulation of key lipid synthesis genes in liver for ZGN vs DIO or age-matched CHOW mice. The insulin- and carbohydrate-responsive genes acetyl CoA carboxylase 1 and 2, fatty acid synthase, stearoyl CoA desaturase 1, and SREBP1c all were down-regulated by 58, 77, 80, 99, and 74%, respectively vs. DIO (all p<0.005), and by 31, 71, 74, 98, and 43%, respectively vs. CHOW (ZGN vs. CHOW, all p<0.05).
Conclusion: Hyperinsulinemia in the setting of diet-induced obesity activates fatty acid biosynthesis and transport pathways, reduces adipose lipolysis, and suppresses ketone body synthesis leading to enhanced triglyceride storage. MetAP2 inhibition appears to be well-tolerated and shows promise as a strategy to reverse hyperinsulinemia and other obesity-associated metabolic adaptations while driving rapid weight loss.

OP 44 Impact of education on glycaemic outcome

245

Patient education: impact on care outcomes, resources consumption and absenteeism. International Diabetes Management Practices Study (IDMPS) data
J.J. Gagliardino[1], P. Aschner[2], S.-H. Baik[3], J. Chan[4], H. Ilkova[5], A. Ramachandran[6];
[1]CENEXA (UNLP-CONICET), La Plata, Argentina, [2]Endocrinology Unit, Bogota, Colombia, [3]Division of Endocrinology, Seoul, Republic of Korea, [4]Department of Medicine and Therapeutics, Shatin, Hong Kong, [5]Department of Internal Medicine, Istanbul, Turkey, [6]India Diabetes Research Foundation, Chennai, India.

Background and aims: Achievement of diabetes treatment goals greatly depends on the patient´s active and efficient participation in the control and treatment of the disease. Even when evidence has demonstrated the value of education to obtain such participation, in many places education is considered an additional cost rather than an important component of diabetes care. This study measures diabetes care indicators and resources consumption in a population of educated and non educated persons with type 2 diabetes.
Materials and methods: The IDMPS is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, Middle East and Latin America. Data were collected from people with type 1 and 2 diabetes (≥18 years) seen in current medical practice in yearly cycles (2-week cross-sectional recruitment period followed by a 9-month longitudinal period for type 2 patients) for 5 years. IDMPS was performed in compliance with the Helsinki Declaration and Good Clinical Practice Standards. We currently report and compare results from 11384 people with type 2 diabetes (educated *vs.* non educated, 5692 in each group, paired by age, gender and diabetes duration) recruited during the second cross-sectional period (November and December 2006). Data were analyzed using the Wilcoxon and the chi^2 tests for continuous and categorical variables, respectively.
Results: The mean age ± SD for both groups was 57.7 ± 11.1 (53.1% female), with an average BMI of 28 ± 5.2 and 8 ± 7 years of diabetes duration. Educated patients had significantly (p< 0.001) higher figures of people with normal BMI (28.3 *vs.* 24.4%), diastolic BP <80 mm Hg (36.5 *vs.* 32.3%), HbA1c < 7.0% (38.1 *vs.* 35.8%), LDL-c < 100 mg/dL (39.5 *vs.* 33%) and triglyceride < 150 mg/dL (52.7 *vs.* 49%). The percentage of complications was low in both groups (<20%), but the educated group had significantly lower values of people with proteinuria (16.6 *vs.* 18%) and foot ulcer (2.4 *vs.* 3.5%). Visits of educated patients to specialists increased by 21%, as well as insulin treatment (40%), fasting (10%) and postprandial (52%) SMBG performance. Absenteeism was 15% lower in educated patients.
Conclusion: These data, one of the largest reported on education of people with type 2 diabetes, demonstrate that education can significantly improve treatment outcomes, with a low increase in resources consumption and a decrease in absenteeism. They also show that education is an efficient tool to improve diabetes care quality with low impact on resources consumption and additional positive impact on productivity, particularly important for developing countries that bear the heaviest part of the global diabetes epidemic.

The effects of a structured educational programme (DAFNE) for individuals with type 1 diabetes on DKA admissions
H. Kahal[1], J.D. Ng[1], D.M. Mellor[1], V. Bansiya[1], A. Rigby[2], S.L. Atkin[3], J. Patmore[1];
[1]Department of Diabetes and Endocrinology, Hull Royal Infirmary, [2]University of Hull, [3]Academic Diabetes, Endocrinology and Metabolism, Hull York Medical School, United Kingdom.

Background and aims: In the UK national diabetes audit 2007/2008, around 10% of people with type 1 diabetes had an episode of Diabetic Ketoacidosis (DKA) within 5 years. Structured education programmes for individuals with Type 1 diabetes are acknowledged as an effective means of delivering skills based training to improve knowledge of diabetes. They aim to influence behaviour and to optimise self management and reduce negative outcomes. Locally we deliver DAFNE, Dose Adjustment for Normal Eating, as a 5 day programme for individuals with type 1 diabetes. DAFNE was introduced in our centre in 2005. The aim of our study was to assess the effects of attend-

ing DAFNE on DKA admissions to an acute University Teaching Hospital in the UK.
Materials and methods: A retrospective review of all individuals with type 1 diabetes who attended a DAFNE course between Oct 2005 and July 2008. Only patients who lived locally and subsequently would have been admitted acutely to our hospital in a case of DKA were selected. We used the hospital coding system to detect all DKA admissions for the same group between Oct 2002 and July 2009.
Results: A total of 236 patients attended the DAFNE course. DKA admissions are summarized in table 1. DKA admission rate in the first year before DAFNE was 0.113 admissions/person/year (95% CI=0.073, 0.165) compared to 0.069 admissions/person/year (95% CI= 0.039, 0.112) in the first year after DAFNE. Relative risk reduction 39% (95% CI= 0, 78%); P= 0.05. For the group of patients with any DKA admission (n= 24), median duration of follow up of 24 months (range 15 - 44) before and after attending DAFNE, DKA admission rate was 2.375 admissions/person/year (95% CI= 1.789, 3.0777) before Vs 1.166 admissions/person/year (95% CI= 0.775, 1.686) after DAFNE. 212 patients had no DKA admissions before or after DAFNE within the same period of follow up.
Conclusion: Attending structured education (DAFNE) resulted in significant reduction in hospital DKA admission rate for individuals with type 1 diabetes. This suggests that offering a structured education might be a productive strategy in reducing DKA admissions in type 1 diabetes.

Table 1. DKA admissions in relation to DAFNE

Time in relation to DAFNE course	2nd year before	1st year before	1st yr after	2nd yr after
No. of DKA admissions	31	26	16	11
No. of patients with data available	217	230	236	163

PRODIACOR: Educative interventions improve clinical and metabolic outcomes and optimise treatment costs in an Argentinean population with type 2 diabetes

G. Pfirter[1], S. Lapertosa[2], M. Villagra[2], J.E. Caporale[1], C. Gonzalez[3], C. Clark Jr.[4], J.J. Gagliardino[1], on behalf of the PRODIACOR Group;
[1]CENEXA (UNLP-CONICET), La Plata, [2]Hospital Vidal, Corrientes, [3]UBA, Buenos Aires, Argentina, [4]Indiana University School of Medicine, Indianapolis, USA.

Background and aims: PRODIACOR is a randomized controlled clinical trial implemented in a primary care setting (Corrientes city, Argentina) aimed at measuring the impact of educative interventions upon quality of care of people with type 2 diabetes (T2DM) and to measure the cost-effectiveness of such interventions.
Materials and methods: 36 primary care physicians and 468 persons with T2DM were randomized at physician level and allocated to 4 groups: 1) patients but not physicians received an education programme, 2) physicians but not patients received an education programme, 3) both physicians and patients received an education programme, and 4) control group (physicians/patients received no education but education material and data feedback). Patients from all groups received complete coverage of drugs and supplies; clinical, metabolic and therapeutic indicators were recorded. Educated physicians attended 4 interactive theoretical-practical modules and received a manual with all the algorithms for diagnosis, control and treatment of T2DM. Educated patient attended 4 weekly teaching units and a reinforcing session after 6 weeks, with a focus at improving health behaviour. Educational material included an individual log-booklet to record the self-monitored data (blood glucose and body weight) and a book with the main contents of the programme. Every patient - irrespective of his group allocation - received a check-book which served 2 purposes: a) as a reminder system for medical visits and laboratory test performance, and b) as a data collection system (record of laboratory tests, consultations or prescriptions for drugs or devices). Physicians monitored and recorded clinical data and data collection was monitored twice a year. We currently report baseline and 3-year follow-up data.
Results: The population age was (Mean±SD) 63±9 years (66% female) and diabetes duration was 10±8 years. After the 3-year follow up we recorded no significant changes in BMI but significant improvements (p<0.001) in all groups in systolic (142±17 *vs.* 134±15 mmHg) and diastolic (87±11 *vs.* 80± 9 mmHg) blood pressure, FBG (8.0±2.5 *vs.* 7.2±2.2 mmol/L), HbA1c (7.8±1.5 *vs.* 7.1±0.8%) and total cholesterol (4.7±0.9 *vs.* 4.4±0.7. mmol/L). All these changes were significantly larger in the intervention groups. The percentage of patients at target for all these parameters was significantly (p<0.01) larger in these groups. In the educated groups, we also recorded a significant increment in combined against oral monotheraphy (42 *vs.* 30%) and insulin use (15 *vs.* 9%). Drug consumption and strips for blood glucose represented 64 and 83% of the total care cost at baseline and 3-year follow up, respectively. This cost increased (113%) in the control group while it significantly decreased (11 to 20%) in the intervention groups, particularly in the patient/physician educated group.
Conclusion: Educative interventions implemented at a primary care level to people with T2DM improved the clinical and metabolic outcomes and optimized the use of drugs for DM and other associated cardiovascular risks factors, decreasing the total costs.

An integrated hospital-community diabetes education network based on self-management school and Telecom

Z.L. Sun[1], L.L. Liu[1], B. Xie[2], C.P. Ju[1], H. Jin[1], Q.S. Lu[1];
[1]Department of Endocrinology, Zhongda Hospital, Southeast University, [2]Medical School, Southeast University, Nanjing, China.

Background and aims: It was shown from new data that China became the global epicentre of the diabetes epidemic with 92.4 million patients. The challenge for China is to find proper ways to deal with the big problem and help diabetic patients to control the disorder. In the present study, we established an integrated hospital-community diabetes education network based on a self-management school and telecommunication system, and evaluated the efficacy of this network on the metabolic control of diabetic patients in community.
Materials and methods: A total of 524 new diagnosed diabetic patients screened in community were recruited and assigned to intensive group (n=266) or control group (n=258). The patients in intensive group were enrolled in diabetes self-management school located in university hospital first to receive a five sequential days diabetes education course which including diabetes knowledge and diabetes self-management skills delivered by multidisciplinary teacher such as physicians, nurse, dietitian and podiatrist. After graduated from this one week duration school patients were back to community and followed up by community doctor and got subsequent regular advice based on educational focus (information, lifestyle behaviors, glucose monitoring and self-management skills) with telephone, short messages or internet. In the control group, subjects received common education lecturer once a week for up to five weeks followed by regular advice. Outcomes were classified as knowledge, self-management skills and glycemic control in one year using questionnaires and laboratory data.
Results: All patients aged from 9 to 79 years, and average age was 55.19±12.67 years (male 274, female 250), there were no significant difference between two groups in age, gender, diabetes duration, education level, work status, type of insurance, HbA1c, blood pressure, BMI and lipid profile at baseline. After intervention with the integrated diabetes education network, the scores for diabetes knowledge and self-management skills were significantly increased from baseline and higher than control group (P<0.05). Mean HbA1c level was reduced from baseline by 2.43% in intensive group but 1.61% in control group. The percentage of patients with HbA1c<6.5% was significantly higher than control group (68.82% vs 18.53%, P<0.01). The rate of patients' BMI meeting criterion (Male 25kg/m^2,Female 24kg/m^2) was elevated from 54.52% to 61.24% in intensive group(P<0.05). However, there were no significant changes in control group.
Conclusion: Evidence supports the positive effectiveness of the integrated hospital-community diabetes education network on knowledge and self-management skills, finally the better glycemic control was demonstrated.

Nesfatin-1-regulated oxytocinergic signalling in the paraventricular nucleus causes anorexia via melanocortin pathway

Y. Maejima[1], U. Sedbazar[1], S. Suyama[1], D. Kohno[1], T. Onaka[1], M. Koike[2], Y. Uchiyama[2], T.L. Horvath[3], M.O. Dietrich[3], M. Mori[4], T. Yada[1];
[1]Physiology, Jichi Medical University, Shimotsuke, [2]Cell Biology and Neuroscience, Juntendo University School of Medicine, Tokyo, Japan, [3]Yale University School of Medicine, New Haven, USA, [4]Gunma University, Maebashi, Japan.

Background and aims: Nesfatin-1 is a recently discovered anorectic peptide derived from nucleobindin2. Nesfatin-1 is localized in several brain areas including the hypothalamic paraventricular nucleus (PVN). Starvation decreases NUCB2 mRNA specifically in the PVN. However, the mechanism underlying anorectic action of nesfatin-1 remains unknown. The aim of this study is to clarify the neural pathway through which nesfatin-1 regulates feeding.
Materials and methods: Cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) in single neurons were measured with fura-2 combined with immunocytochemical cell identification. The guide cannula was placed stereotaxically into the third ventricle (3V) in Wistar rats or Zucker fatty Rats. Oxytocin (Oxt) releases from PVN slices were measured by radioimmunoassay.
Results: After 3V injection of nesfatin-1, c-FOS was induced in several hypothalamus nuclei including the PVN and in the brain stem nucleus tractus solitarius (NTS). Intra-PVN injection of nesfatin-1 decreased food intake, suggesting that PVN was one of the target sites for nesfatin-1-induced anorexia. 3V nesfatin-1 injection induced c-FOS substantially in the PVN Oxt neurons. In the PVN, nesfatin-1 increased $[Ca^{2+}]_i$ in single neurons immunoreactive to Oxt, nesfatin-1 and both. In the PVN slices, nesfatin-1 stimulated Oxt release. Immunoelectron micrographs revealed nesfatin-1 specifically in the secretory granules of PVN neurons, and immuno-neutralization against endogenous nesfatin-1 suppressed Oxt release in the PVN slices. These results suggested the paracrine and/or autocrine action of nesfatin-1 in the PVN. Nesfatin-1-induced anorexia was suppressed by an Oxt receptor antagonist. Furthermore, Oxt-induced anorexia was abolished by SHU9119, a melanocortin 3/4 receptor (MC3/4R) antagonist, suggesting that MC3/4R is involved in the downstream of nesfatin-1-regulated Oxt neurons. Moreover, Oxt terminals were closely associated with proopiomelanocortin (POMC) neurons in the NTS, and Oxt increased $[Ca^{2+}]_i$ in single POMC neurons in the NTS. In Zucker fatty rats whose leptin receptors are mutated, 3V injection of Oxt induced anorexia that was blocked by SHU9119. The incidence of $[Ca^{2+}]_i$ responses to leptin in NTS POMC neurons was markedly reduced in Zucker fatty rats compared with lean rats. In contrast, the incidence of $[Ca^{2+}]_i$ responses to Oxt in NTS POMC neurons was the same between Zucker fatty and lean rats. This result indicates that Oxt can activate the NTS POMC neurons under leptin-resistant conditions.
Conclusion: Nesfatin-1 activates the activity and secretion of Oxt neurons in the PVN, and Oxt activates POMC neurons in the NTS. This pathway can function independently of leptin signaling and may provide a therapeutic target for treatment of leptin-resistant obese humans showing hyperphagia.

Role of brain insulin signalling on tissue-specific glucose disposal

C.P. Coomans[1], N.R. Biermasz[1], L.M. Havekes[2], J.A. Romijn[1];
[1]Endocrinology, Leiden University Medical Center, [2]The Netherlands Organization for Applied Scientific Research - BioSciences, Gaubius Laboratory, Leiden, Netherlands.

Background and aims: Circulating insulin inhibits hepatic glucose production and stimulates glucose uptake in peripheral tissues. Hypothalamic insulin signaling is required for the inhibitory effects of circulating insulin on endogenous glucose production. In this study, we examined the central effects of circulating insulin on tissue-specific glucose uptake.
Materials and methods: Tolbutamide, an inhibitor of ATP-sensitive potassium channels, was infused in the lateral ventricle (i.c.v.) in hyperinsulinemic euglycemic clamp conditions in chow-fed and in diet-induced obese C57Bl6/J mice. Whole body glucose uptake was measured by D-[^{14}C]glucose kinetics and tissue-specific glucose uptake by 2-deoxy-D-[^{3}H]glucose uptake.
Results: I.c.v. administration of tolbutamide impaired the ability of circulating insulin to inhibit endogenous glucose production by ~20% (P<0.01). Surprisingly, i.c.v. tolbutamide infusion also diminished insulin-stimulated glucose uptake by muscle (-59%; P<0.05), but not by heart or adipose tissue. In contrast, in diet-induced obese mice, high fat feeding abolished the inhibitory effect of i.c.v. tolbutamide on insulin-stimulated glucose production or muscle glucose uptake.
Conclusion: Circulating insulin stimulates glucose uptake in muscle in part through effects via ATP-sensitive potassium channels in the central nervous system, similarly to the effects on hepatic glucose production. In diet-induced obese mice, these effects of circulating insulin via the central nervous system are absent. These observations stress the role of the central effects of circulating insulin in normal physiological conditions and in diet-induced insulin resistance.

Lipoprotein lipase inhibition in rat hippocampus leads to increase in body weight, fat mass, and basal insulinaemia without change in food intake

A. Picard, C. Rouch, C. Magnan, C. Cruciani-Guglielmacci;
Université Paris 7, France.

Background and aims: Regulation of energy balance implies peripheral signals (hormones, nutrients) conveying to specialized brain areas. Among them, the hypothalamus and the hindbrain contain both glucose and free fatty acids (FFA) sensitive neurons, which have been demonstrated to be part the central integration of circulating signals of hunger and satiety. However other brain structures associated with the higher-order behavioral response, such as hippocampus, may also participate on the processing of these signals. Hippocampus is densely populated with both ghrelin, leptin and insulin receptors as well as with lipoprotein lipase (Lpl). Thus we postulated that triglycerides hydrolysis by lipoprotein lipase within the hippocampus may play a role in the control of energy homeostasis through local FFA delivery.
Materials and methods: Osmotic minipumps were stereotactically inserted in the hippocampus of male Wistar rats. They received a chronic infusion of tyloxapol (an inhibitor of Lpl activity, 10 µg/day, TYL), or saline (SAL) during 28 days. Food consumption and body weight were measured daily and body composition was analyzed weekly. Between day 20 and day 24, rats were placed in metabolic cages to study metabolic parameters. On day 23, ghrelin orexigenic response (10 nmol IP) was evaluated. On day 27, feeding response to mild hypoglycemia induced by insulin (1 UI/rat) was also analyzed. In another series of experiment, rats were imposed a 24 hour fast. Hippocampus and cortex were collected for the measurement of Lpl activity.
Results: 28 days after minipump implantation, the Lpl activity in hippocampus of TYL rats was decreased by 26% (TYL: 0.91 ± 0.03 U/mg vs. SAL: 1.24 ± 0.08 U/mg, p<0.005) ; TYL rats have gained significantly more weight (TYL: 141.7 ±1.1% vs SAL: 134.6 ±2.8% , p<0.005) than SAL rats while the cumulative food intake stayed unchanged. Increase in fat mass (TYL:+ 20.6 ± 2.4% vs SAL: +9.5 ± 1.5%, p<0.05) accounted for most of body weight gain. This increased fat storage was neither due to a decreased energy expenditure as measured by indirect calorimetry nor to a decrease in total activity. Glycemia, circulating FFA and TG were similar between the two groups, whereas TYL rats displayed basal hyperinsulinemia (TYL: 694.1 ± 42.7pM vs SAL: 485.6 ± 40.6 pM, p<0.05). Food intake measurements after a 24 hour fast or after an insulin challenge were the same in SAL and TYL rats, whereas TYL rats displayed a decreased response to ghrelin (TYL: 5.6 ± 4.6 g/kg vs SAL: 13.9 ± 5.8 g/kg after 4 hours, p<0.05), indicating a potential adaptive mechanism to surfeit food intake and further weight gain.
Conclusion: The inhibition of hippocampal LPL activity by a chronic tyloxapol infusion led to a gain in body weight without any modification of food intake, plasma TG and FFA, and antagonized the orexigenic action of ghrelin. Moreover, tyloxapol-infused rats displayed a hyperinsulinemia without any change in blood glucose, suggesting an autonomic adaptation leading to mild peripheral insulin resistance. Taken together these results support the idea that hippocampal TG hydrolysis might directly influence energy balance regulation at both the metabolic and behavioral levels.

Hypothalamic leptin improves mitochondrial function in soleus muscle: The role of PI3K signalling

E.A. Roman[1], A.P.S. Arruda[1], T. Romanatto[2], C. Solon[1], J. Morari[1], C.E.C. Nuñez[1], L.A. Velloso[1], M.A. Torsoni[3];
[1]University of Campinas, [2]University of São Paulo, [3]University of Braz Cubas, Mogi das Cruzes, Brazil.

Background and aims: Complex metabolic diseases such as obesity and type 2 diabetes mellitus (DM2), result from multiple interactions between genetic and environmental factors. DM2 is characterized by insulin resistance in skeletal muscle and other insulin-sensitive tissues, which is accompanied by defective insulin secretion. Muscle insulin resistance is manifested by a reduced capacity of insulin to stimulate glucose uptake due to impaired intracellular signaling. Additionally, insulin-resistant subjects present a reduced capacity to oxidize glucose and lipids in muscle which, at least in part, is due to impaired mitochondrial activity as evidenced by reduction of mitochondrial oxidative and phosphorylative activities. Acting in the hypothalamus, anorexigenic hormones such as leptin and insulin, as well as nutrients can modulate peripheral glucose homeostasis. Some of these effects depend on neural control of hepatic gluconeogenesis. However, the mechanisms by which hypothalamic leptin leads to improved glucose homeostasis in skeletal muscle are incompletely known. The aim of this study was to investigate the molecular mechanism by which ICV leptin improves glucose homeostasis in skeletal muscle.
Materials and methods: Rats were divided in three groups: i) Control (Saline-ICV); ii) Leptin (Leptin-ICV); and, iii) LYL (Ly 294002 + Leptin-ICV). The expressions of PGC1α, Cytochrome c and UCP3 expression was performed by Western Blotting; Citrate synthase activity was analyzed by an espectrophotometric assay and mitochondrial respiration was measured in soleus muscle fibers, permeabilized with saponine, by a high-resolution respirometry assay (OROBORUS). All procedures were approved by the Ethics Committee at the University of Campinas.
Results: The central administration of leptin increased PGC1α expression (>100 %) in skeletal muscle and the ICV administration of Ly 294002 (inhibitor of PI3K) prior to leptin inhibited this effect. Similar effect was observed in Cytochrome c and UCP3 expressions, which increased 480 % and 43 %, respectively, after ICV leptin injection if compared to control group and the previous administration of Ly (ICV) reduced these effects. In addition, leptin injection (ICV) increased the activity of Citrate synthase (80 %) and mitochondrial respiration (18 %) compared to control group.
Conclusion: Leptin injection (ICV) is able to modulate the expression of proteins and mitochondrial function in the skeletal muscle in a hypothalamic PI3K-dependent manner.

Low-cost screening model with standard cardiometabolic risk factors for prediction of incident type 2 diabetes: the Whitehall II study

A. Heraclides[1], D. Vistisen[1], E.J. Brunner[2], A.G. Tabák[2,3], M. Kivimäki[2], J. Ferrie[2], D.R. Witte[1,2];
[1]Epidemiological Research, Steno Diabetes Center, Gentofte, Denmark, [2]Department of Epidemiology and Public Health, UCL, London, United Kingdom, [3]1st Department of Internal Medicine, Semmelweis University Faculty of Medicine, Budapest, Hungary.

Background and aims: Accurate prediction of incident type 2 diabetes (T2DM) is pivotal in enhancing strategies for diabetes prevention and cardiovascular risk management. Current strategies generally include a blood sample in a first or second stage, but few studies have systematically compared the accuracy of multiple alternative predictive models. We examined the predictive capability of 5 screening models for incident T2DM in incremental stages of accessibility and cost.
Materials and methods: We tested the following models in a cohort of 4352 men and women aged 39-64 years, free from diabetes (the Whitehall II study): (A) questionnaire only (age; gender; BMI; family history of diabetes; use of antihypertensive/lipid lowering medication); (B) clinical (previous model + blood pressure + waist circumference); (C) low-cost biomarker (previous + fasting glucose + fasting triglycerides + total cholesterol + HDL-cholesterol); (D) medium-cost biomarker (previous + fasting insulin); and (E) high-cost biomarker (previous + ApoA1/B + lipoprotein(a)+ CRP + IL-6 + fibrinogen + von Willebrand factor + factor VII).
Results: Multivariate Cox regression analysis was used to estimate predictive models for 20-year incident T2DM (574 cases). We used a 2-step approach: (i) Receiver Operating Characteristics (ROC) analysis for assessing the improvement in prediction of each subsequent model; and (ii) Based on the results from ROC analysis, backwards elimination analysis for deriving a parsimonious model without reducing predictive performance. The Area Under the ROC Curve (AUC) was higher in all 3 screening models requiring a blood sample (Models C-E) compared to the questionnaire/clinical screening models (Models A and B) (table 1). Compared to model A, the 'clinical model' (B) was not better in predicting incident T2DM (AUC difference=0.001). The 'low-cost biomarker model' (C), improved significantly Model B (AUC difference=0.054). Only marginal improvement was found beyond Model C (addition of fasting insulin and detailed lipid/inflammatory markers) (AUC difference=0.008 and 0.007 respectively). In backwards elimination, we estimated a parsimonious model, which did not reduce the prediction of Model C, containing age, gender, BMI, family history of diabetes, use of antihypertensive/lipid lowering medication, fasting glucose, fasting triglycerides and HDL-cholesterol.
Conclusions: A questionnaire/clinical screening model for predicting incident T2DM is substantially improved by a low-cost blood sample test containing fasting glucose, triglycerides and HDL-cholesterol. Improvements to this model by addition of higher cost biomarkers are not of a clinically relevant magnitude.

Table 1 Area under the ROC curve for additive screening models

Predictive models for incident type 2 diabetes	Area under curve (95% CI)	p for model improvement
Questionnaire only - model A (sex + age + family history of diabetes + use of antihypertensive or lipid lowering medication + BMI)	0.72 (0.69; 0.75)	n/a
Clinical - model B (questionnaire + blood pressure + waist circumference)	0.72 (0.69; 0.75)	0.72
Low-cost biomarker - model C (clinical model + fasting glucose + triglycerides + total cholesterol + HDL-cholesterol)	0.78 (0.75; 0.81)	<0.001
Medium-cost biomarker - model D (low-cost biomarker + fasting insulin)	0.79 (0.76; 0.82)	0.001
High-cost biomarker - model E (medium-cost biomarker + ApoA1/B + Lp(a) + CRP + IL-6 + fibrinogen + vWf + factor VII)	0.79 (0.76; 0.82)	0.015

The risk of incident diabetes for all possible combinations of metabolic syndrome components

G.A. Nichols[1], E.J. Moler[2];
[1]Kaiser Permanente Center for Health Research, Portland, [2]Tethys Bioscience, Inc, Emeryville, USA.

Background and aims: Because metabolic syndrome (MetS) is defined as any three of five criteria, not all persons with MetS have the same cluster of risk factors. Whether the various combinations of criteria confer equal diabetes risk is not known. Our aim was to estimate the risk of incident diabetes simultaneously for all possible combinations of MetS components.
Materials and methods: Using electronic medical record data from a group model HMO, we identified an observational cohort of 58,056 non-pregnant adults age ≥ 30 with no evidence of diabetes and all MetS components measured in 2003-2004. Subjects were followed for up to 5 years for onset of type 2 diabetes. We estimated age and sex-adjusted diabetes incidence for all possible combinations of MetS components.
Results: The overall incidence rate of diabetes was 12.5/1,000 person-years (95% CI 12.1-12.9). The presence of each individual MetS component was associated with significantly greater diabetes incidence than absence of the component. The greatest relative difference was found among those with impaired fasting glucose, with an age and sex-adjusted incidence of 37.4/1000 person years (36.0-38.9) compared to 3.8 (3.6-4.1) among those with normal glucose. Although persons with 1 or 2 MetS factors comprised about 50% of the sample, diabetes occurred in fewer than 5% of these individuals. While the proportion of the sample declined with each additional factor, the proportion developing diabetes increased precipitously with the number of factors present, reaching 28% among those with all 5 components. However, there was wide variation within each count of factors. Depending on which factors were present, incidence varied by >9-fold in patients with 3 risk factors, >5-fold in patients with 4 factors, and >54-fold in patients with <3 factors. Specifically, there was a clear separation between combinations that did and did not include hyperglycemia. In fact, all two-factor combinations that included hyperglycemia had higher incidence rates than three- or four-factor combinations that did not. For example, incidence in patients with only hyperglycemia and obesity was 21.7/1000 person-years (95% CI 17.4-27.1), compared to 11.4 (9.8-13.4) among those with the four component combination of obesity, hypertension, low HDL and elevated triglycerides.
Conclusion: Diabetes risk increases exponentially with MetS factor count, but varies substantially depending upon which factors are present. Hyperglycemia, regardless of the presence of MetS, is a much stronger predictor of incident diabetes than MetS without hyperglycemia.

Physiological predictors of changes in glucose tolerance in a non-diabetic population: the RISC Study

A. Natali[1], E. Muscelli[1], B.D. Astiarraga[1], A. Mari[2], E. Ferrannini[1], on behalf of the RISC Study Investigators;
[1]Department of Internal Medicine, University of Pisa, [2]Institute of Biomedical Engineering, National Research Council, Padova, Italy.

Background and aims: Previous studies using the euglycaemic insulin clamp technique have reported that both insulin resistance and a reduced acute insulin response to intravenous glucose (AIR) predict incident diabetes in isolates (the Pima Indians). We undertook to systematically analyse the relationship between insulin sensitivity/secretion and spontaneous changes in glucose tolerance in non-diabetic subjects.
Materials and methods: In 1,048 subjects from the RISC cohort (561 women and 467 men, mean age 44 years) followed up for 3 years, we measured baseline insulin sensitivity (by a 240 pmol.min.m-2 insulin clamp) and ß-cell function (i.e., fasting insulin secretion rate, total insulin output and ß-cell glucose sensitivity, by mathematical modelling of the C-peptide response to a standard OGTT). Subjects were categorised as NGT, IFG, IGT or T2D and then grouped into stable NGT (if they were NGT both at baseline and follow up, n=809), stable non-NGT (if they were IFG or IGT on both occasions, n=49), progressors (if their glucose tolerance deteriorated, n=129) or regressors (if their glucose tolerance improved, n=61).
Results: In comparison with stable NGTs, progressors, regressors and stable non-NGTs presented a similar clinical (higher prevalence of familial diabetes, older age and higher WHR, fasting and 2-hour plasma glucose, fasting and 2-hour plasma insulin concentrations) and metabolic phenotype (lower insulin sensitivity and reduced ß-cell glucose sensitivity with increased fasting secretion rate and total insulin output). In a multivariate logistic model, both insulin sensitivity and glucose sensitivity were independent negative predictors of progression (odds ratios [95% CI] of 0.70 [0.52-0.93] and 0.42 [0.28-0.65], respectively), while WHR and fasting glucose le-vels were positively associated with progression. The same set of baseline variables also predic-ted regression. At follow up, insulin sensitivity and ß-cell glucose sensitivity were unchanged in the stable NGTs and non-NGTs, declined in the progressors and improved in the regressors.
Conclusion: Among non-diabetic Caucasians, non-NGTs, progressors and regressors appear to derive from a common pool of at-risk subjects, in whom reduced insulin sensitivity and impaired ß-cell glucose sensitivity predict deterioration of glucose tolerance. Changes in both insulin sensitivity and ß-cell glucose sensitivity mark progression as well regression of dysglycaemia.

Serum fibroblast growth factor 21 and triglycerides independently predict the development of type 2 diabetes

B. Angelin[1], A. Hilding[1], C.-G. Östenson[1], H.A. Bina[2], A. Kharitonenkov[2], M. Rudling[1];
[1]Department of Endocrinology, Metabolism & Diabetes, Karolinska Institutet and University Hospital, Stockholm, Sweden, [2]Lilly Research Laboratories, Indianapolis, USA.

Background and aims: There is a need to identify novel factors that more accurate predict the risk of developing type 2 diabetes (T2D. Circulating levels of both fibroblast growth factors 19 and 21 (FGF19 and FGF21) show a large interindividual variation in normal humans. Case-control studies have reported correlations between FGF21 and impaired glucose tolerance, insulin resistance, hypertriglyceridemia, obesity and/or T2D. We tested the hypothesis that fasting levels of FGF19, FGF21 or triglycerides could predict the subsequent development of prediabetes (IFG, IGT) or T2D in a healthy cohort followed for a ten-year period.
Materials and methods: In the Stockholm Diabetes Prevention Program (SDPP), a total of 2227 men and 3205 women with normal glucose tolerance were followed-up after ten years. We identified 461 subjects with abnormal glucose regulation (163 with T2DM, 97 of which were newly diagnosed) and compared them with 479 matched controls that remained normal at follow-up. Serum levels of FGF19 and FGF21 were analyzed by ELISA.
Results: At baseline in all subjects (n=940; 396 F and 544 M), mean age was 48.2 yr, BMI 26.3, fasting glucose 4.73 mM, cholesterol 6.23 mM, triglycerides 1.45 mM, FGF19 139 pg/mL, and FGF21 193 pg/mL. At follow-up, subjects with prediabetes or T2D had significantly higher levels of FGF21, 262 and 328, respectively, compared to controls,179; P<0.001 and of triglycerides (1.83 and 2.07 versus 1.33; P<0.001); FGF19 and cholesterol levels were similar, and there were no gender differences. When baseline levels were analyzed in the groups, FGF21 levels were higher in both women and men who later developed prediabetes (213; 228) or T2DM (241; 286) compared to controls (150; 165). This was also seen for triglycerides (prediabetes, F/M, 1.45; 1.86; T2DM, 1.69; 1.89 versus controls 1.11; 1.32); all differences were highly significant (P<0.001). FGF19 or cholesterol did not show any relation to development of glucose intolerance or T2DM. Adjusted for age, BMI, physical activity, smoking, and socioeconomic position, FGF21 and triglyceride level

still predicted an increased risk for glucose intolerance or T2DM (OR for women, 1.91 and 3.63, for men, 2.36 and 4.04, for highest quartile of FGF21; OR for women, 3.33 and 6.82, for men, 3.17 and 2.26 for highest quartile of triglycerides). BMI, FGF21, and triglycerides were shown to be independent as risk predictors when combining women and men in the logistic regression analysis.
Conclusion: Elevated fasting levels of circulating triglycerides and FGF21, but not of FGF19, are associated with a substantially increased risk to develop prediabetes or T2DM in humans. Both elevated FGF21 and triglycerides are independent of each other and of BMI, and point to the presence of an early state of metabolic abnormality predisposing to glucose intolerance. High levels of circulating FGF21 may reflect a state of "resistance" to this newly described metabolic regulator.

Gene-metabolite networks for signature of insulin action in humans
N.N. Rudovich[1,2], V.J. Nikiforova[3], O. Pivovarova[1], A. Erban[3], Ö. Gögebakan[1], A.F.H. Pfeiffer[1];
[1]Clinical Nutrition, DIFE Potsdam-Rehbrücke, Nuthetal, [2]Endocrinology, Diabetes and Nutrition, Charité University Medicine Berlin, [3]Max Planck Institute of Molecular Plant Physiology, Potsdam, Germany.

Background and aims: Insulin is a key metabolic hormone in the body. Few studies describe insulin-dependent transcriptome changes and no data exist for insulin-related plasma metabolome. We investigated the regulation of subcutaneous adipose tissue (SAT) gene expression during different glucose/insulin concentrations and its relation with insulin-induced changes of plasma metabolome.
Materials and methods: Healthy subjects (n=14) underwent a saline-infusion test (INF) and/or a hyperinsulinemic-euglycemic clamp (EC), and/or a hyperinsulinemic-hyperglycemic clamp (HC). SAT biopsy and plasma samples were taken before and at 240 min of the tests. Full human genome Agilent chips were used for transcript profiling, and GC-TOF/MS analysis was applied to get the metabolome of plasma. We created a gene-metabolite network for each experiment and extracted the insulin effects in respect to blood glucose concentrations by alternative network subtraction analysis.
Results: Insulin down regulates about 16% of plasma metabolome under euglycemia, while simultaneous expressional changes are only minor. In the HC experiments, more metabolites were up-regulated. In the subtracted network of EC, insulin was directly connected only with two genes and two metabolites (tetradecanoate and octadecanoate). Moreover, a clock-gene NR1D2 was a major "hub" in this network and was negatively correlated with insulin. The resting network structure included the six hubs of predominantly fatty asides and their derivates. In the network of HC, the major "hub" was fructose. From the six genes, included in this network, five were genes encoding transcriptional factors.
Conclusion: "Gen-metabolite signatures" of insulin action allow us to visualize insulin-dependent patterns of gene-metabolite interactions and help to further understand the mechanisms involved in the pathogenesis of obesity and T2DM.

Urinary proteome analysis for diagnosis of diabetic nephropathy
P. Zürbig[1], P. Rossing[2], G.J. Navis[3], I. Rychlík[4], B.M. Winklhofer-Roob[5], H. Mischak[1,6];
[1]Mosaiques Diagnstics GmbH, Hannover, Germany, [2]Steno Diabetes Centre, Gentofte, Denmark, [3]University Medical Centre Groningen, Netherlands, [4]Second Department of Internal Medicine, Third Faculty of Medicine, Charles University, Prague, Czech Republic, [5]Human Nutrition & Metabolism Research and Training Center, Institute of Molecular Biosciences, Karl Franzens University of Graz, Austria, [6]BHF Glasgow Cardiovascular Research Centre, University of Glasgow, United Kingdom.

Background and aims: Diabetic nephropathy (DN) is a leading cause of morbidity and mortality in people with diabetes mellitus. Current clinical methods to predict development of diabetic kidney disease are subject to measurement variability and lack predictive power. In several recent studies, it has been shown that urinary proteome analysis enables the definition of biomarkers specific for chronic kidney disease (CKD) in general and for DN; both models includes in the majority different collagen fragments. These might prove valuable in clinical practice, but confirmation of their diagnostic value in independent patient population not included in the original samples used in discovery is required to support their validity and robustness. Therefore, we aimed to validate these biomarkers and biomarker-based models in an independent blinded set of 148 samples, collected prospectively in multiple centers not involved in the original identification of biomarkers to rule out any center-based bias.
Materials and methods: Cases of diabetic nephropathy were defined as albuminuria >300 mg/d and diabetic retinopathy (n=66). Controls were matched for gender and diabetes duration (n=82). High-resolution capillary-electrophoresis coupled to time-of-flight mass-spectrometry (CE-MS) was used to profile the low-molecular-weight proteome in urine of these type 2 diabetic

patients. CE-MS spectra were evaluated employing the previously developed biomarker models for all case and control patients in a blinded setting.
Results: Urinary profiling using CE-MS was successfully applied to urine samples of diabetic patients with or without existing DN. Models for the diagnosis of CKD in general and for the identification of patients with DN in particular, were validated with this multicentre blinded test set and allowed diagnosis of DN with high accuracy (AUC>0.94) (see figure). Furthermore, 61 of the 65 previously identified peptides (94%) were significantly different between these cases and controls.
Conclusion: These data provide the first independent confirmation that profiling of the urinary proteome by CE-MS can adequately identify subjects with DN, supporting the generalizability of this approach. The data further establish urinary collagen fragments as biomarkers for diabetes-induced renal damage that may serve as earlier and more specific biomarkers than the currently used urinary albumin.

Quantitative proteomic analysis of the adipocyte plasma membrane proteome identifies the Sodium/Hydrogen exchanger NHE6 as a novel insulin-responsive protein

M.J. Prior[1], M. Larance[1], J. Soul[1], J. Burchfield[1], H. Kanazawa[2], M. Raftery[3], D.E. James[1];
[1]Diabetes and Obesity Program, Garvan Institute of Medical Research, Sydney, Australia, [2]Department of Biological Science, Osaka University, Machikaneyama, Japan, [3]Bioanalytical Mass Spectrometry Facility, University of New South Wales, Sydney, Australia.

Background and aims: In mammals the maintenance of glucose homeostasis is achieved via insulin-stimulated translocation of the glucose transporter GLUT4 to the plasma membrane (PM) of adipocytes and myotubes. After insulin stimulation the PM is the target membrane for intracellular vesicles containing GLUT4 and so the proteins present there both before and after insulin stimulation along with their phosphorylation status are of great interest. In order to identify novel regulators of insulin-stimulated GLUT4 translocation to the PM, we conducted a quantitative and comprehensive proteomic screen of this organelle, before and after insulin stimulation. We have also taken advantage of the high binding affinity between many of the substrates of Akt, a key regulator of insulin stimulated GSV translocation, and 14-3-3, by using 14-3-3 affinity chromatography to identify novel insulin-regulated phospho-proteins acting downstream of this kinase at the PM.
Materials and methods: Stable isotopes were incorporated into mouse 3T3-L1 adipocytes and protein abundance and 14-3-3 binding in the PM from unstimulated cells, cells treated with 100 nM insulin for 20 minutes and cells treated with insulin plus the PI3Kinase inhibitor wortmannin was quantitated by LC-MS/MS and immunoblotting. PM fractions were isolated using cationic colloidal silica and these were further fractionated by a high salt, high pH wash. 14-3-3 binding proteins were identified using human 14-3-3-beta coupled to cyanogen bromide activated Sepharose 4B and all LC-MS/MS data were processed, searched and quantified using the Maxquant software version 1.0.13.13 package.
Results: These studies revealed 35 proteins that underwent insulin-dependent translocation to the PM and included both known (GLUT4, IRAP, Transferrin receptor protein-1, Cation-dependent mannose-6-phosphate receptor and Syntaxins -6 and -12) and previously unknown insulin-responsive proteins. An additional 9 insulin-responsive proteins, including cGMP-inhibited 3',5'-cyclic phosphodiesterase B were identified by 14-3-3 pull-down. More detailed studies using a Sodium/hydrogen exchanger memeber 6 (NHE6) specific antibody showed that this protein underwent a 2-3 fold increase at the PM and is expressed predominantly in brain and adipose tissue. Furthermore, in 3T3-L1 fibroblasts, NHE6 protein expression is up-regulated during the differentiation process and is partially co-localised with GLUT4.
Conclusion: The approach demonstrated here has led to the most extensive characterisation of a mammalian PM proteome and its constituent insulin-responsive compartments. Differential analysis identified 27 novel insulin-responsive proteins, including the sodium/hydrogen exchanger NHE6. Insulin-stimulated NHE6 translocation may explain the observed elevation in intracellular pH induced by this hormone and thus NHE6 may play an important role in insulin action.

Urinary collagen fragments are significantly altered in diabetes: a link to pathophysiology

J. Siwy[1], D.M. Maahs[2], H. Mischak[1,3], P. Rossing[4], E. Schiffer[1], J.K. Snell-Bergeon[2], P. Zürbig[1];
[1]Mosaiques Diagnostics Inc., Hannover, Germany, [2]Barbara Davis Center for Childhood Diabetes, University of Colorado Denver, Aurora, USA, [3]BHF Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom, [4]Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Although all forms of diabetes mellitus (DM) are characterized by hyperglycemia and β-cell dysfunction, the pathogenesis of DM is variable, comprising different degrees of β-cell dysfunction, apoptosis, inflammation and immune responses. Proteome analysis holds the promise of delivering substantial insight into the pathophysiological changes associated with different types of diabetes. Recently, we identified and validated urinary proteomics biomarkers for diabetes, and diabetes-associated micro- and macrovascular complications. Based on these initial findings, we aimed to further validate urinary proteomics biomarkers specific for diabetes in general, and specifically associated with either type 1 (T1D) or type 2 diabetes (T2D).
Materials and methods: The low-molecular-weight urinary proteome of 902 subjects from 9 different clinical centres, 315 controls and 587 patients with T1D (n=299) or T2D (n=288), was analyzed using capillary-electrophoresis mass-spectrometry.
Results: A previously discovered panel of 261 urinary biomarkers (102 were sequenced) based on 205 subjects distinguished DM subjects from control subjects with 94% (95% CI: 92-95) accuracy in 697 independent subjects. To identify biomarkers that differentiate T1D from T2D, a subset of normoalbuminuric patients with T1D (n=68) and T2D (n=42) was employed, enabling tentative identification of 204 biomarker candidates (68 were sequenced) differentially regulated between T1D and T2D. These biomarkers distinguished T1D from T2D in an independent validation set of normoalbuminuric patients (n=108) with 93% (95% CI: 86-97%) accuracy. When applied to patients with impaired renal function (n=369) accuracy was 91% (95% CI: 88-94%). Most of the biomarkers significantly associated with diabetes, and those that are apparently diabetes-type specific, were specific collagen fragments, indicating highly significant changes in collagen turnover and extracellular matrix as one hallmark of the molecular pathophysiology of diabetes. Additional indications for chronically sustained renal injury mediated by inflammatory processes and pro-thrombotic alterations were observed.
Conclusion: These findings, based on the largest proteomic study ever performed on subjects with DM, pinpoint potential differences in the pathophysiology of T1D and T2D that may improve understanding of diabetes and diabetes-associated complications and result in improved therapeutic strategies.

Age-related and islet autoimmunity associated differences in metabolites of the amino acid and lipid metabolism in children at high risk for type 1 diabetes

M. Pflueger[1], A.-G. Ziegler[1], P. Achenbach[1], M. Orešič[2];
[1]Institut fuer Diabetesforschung Helmholtz Zentrum Munich, Germany, [2]VTT Technical Research Centre of Finland, Espoo, Finland.

Background and aims: Data from the BABYDIAB study demonstrate that islet autoimmunity in children of mothers or fathers with type 1 diabetes (T1D) is initiated early in life with two phenotypically distinct peaks of antibody incidence before age 4 and after age 7 years. Changes in lipid and amino acid metabolism are suggested to precede the development of T1D. The aim of this study was to examine whether there are changes in serum metabolite profiles (metabolomics) which are characteristic for early (< age 4 years) compared to late (> age 7 years) initiation of islet autoimmunity.
Material and methods: Metabolites of the amino acid and lipid metabolism were measured in samples from 70 BABYDIAB children, including 13 who developed islet autoantibodies (AA) early (< age 4 years) and 22 who developed islet AA late (> age 7 years), and 35 age, date of birth, and HLA-matched children who remained islet AA negative ('controls'). Metabolites and lipids were measured quantitatively in the first antibody positive serum sample or in aged-matched samples of 'controls' using UPLC coupled with UV detection and UPLC-MS, respectively. The 511 detected molecular lipids were clustered into 12 groups (LC). Concentrations were compared using the Mann-Whitney-U-Test.
Results: Specific changes in metabolite and lipid profiles were identified in BABYDIAB children. These included both age-related and antibody appearance related. Regardless of antibody status, children aged >7years had higher concentrations of glutamine (p=0.004), arginine (p=0.008), glycine (p<0.0001), and citric acid (p=0.006) as compared to children <4years of age. Similarly, older children had higher concentrations of LC 2 and 4 which represent proinflammatory lysophosphatidylcholines and sphingomyelins compared to younger children (p<0.0001 and p=0.002), respectively, whereas younger children had higher concentrations of lipids in LC10, containing saturated triglycerides, as compared to older children (p<0.0001). Related to the appearance of islet AA we found lower concentrations of methionine (p<0.0001), ethanolamine (p=0.02) and glutamic acid (p=0.03) in children who developed islet AA early, and lower concentrations of hydroxyproline in children who developed islet AA late as compared to islet antibody-negative children of the respective age-group (p=0.03). Furthermore for both age groups (early and late) we found higher concentrations of LC8, a functionally diverse lipid cluster of specific phospholipids and triglycerides, in children developing islet AA compared to children who remained islet antibody-negative (p=0.0001).
Conclusion: These data demonstrate that there are changes in metabolomic profiles that appear specifically associated with the appearance of islet autoantibodies and with the age of antibody seroconversion. These changes may reveal important novel pathways related to the pathogenesis of autoimmune diabetes. Additional marked age related changes of metabolomic profile which are independent of autoimmunity indicate that age is an important confounder for any future studies using metabolomics technology.

A distinct metabolic profile at birth identifies children developing type 1 diabetes before 20 years of age

D. La Torre[1], Å. Lernmark[1], P. Spégel[1], H. Elding Larsson[1], S.A. Ivarsson[1], M. Orešič[2];
[1]Clinical Sciences, Lund University, Malmö, Sweden, [2]VTT Technical Research Centre of Finland, Espoo, Finland.

Background and aims: Islet autoantibodies are early markers of developing type 1 diabetes and are useful for disease prediction. Recent data suggests that metabolomics analysis may uncover metabolic disturbances prior to seroconversion and clinical diabetes, and that specific alterations may already be detectable at birth. The aim of this study was to confirm evidence of altered metabolic pattern at birth in children who developed type 1 diabetes before 20 years of age.
Materials and methods: Unbiased metabolomics analysis was applied in a case-control analysis of paired cord blood samples from 24 children diagnosed with type 1 diabetes at a median age of 17 years (range 3.2-18.8) and an equal number of healthy controls matched for age (year/month/day) and gender. Cord blood serum from the cases and controls was collected in 1970-1991. All samples were stored frozen at -20°C and had been subjected to an equal number of freeze-thaw cycles. Children born to diabetes mothers were excluded. The analysis of coded samples was performed randomly by Gas Chromatography/Time-of-Flight Mass Spectrometer (Pegasus 4D; Leco). The potential effect of long-term storage on metabolites was investigated through Spearman´s *rho* correlation between metabolite concentrations and sample age. Paired case-control differences were calculated with nonparametric Wilcoxon rank-sum test ($p<0.05$ considered significant).
Results: The type 1 diabetes progression related changes were detected in specific groups of metabolites. The cord blood serum metabolome from the children who develop type 1 diabetes showed 1.2-1.4 -fold higher concentrations of several fatty acids compared to the controls: linoleic acid $p<0.008$, myristic acid $p<0.002$, lauric acid $p<0.002$, stearic acid $p<0.017$, palmitoleic acids $p<0.02$. Oleic and palmitic acid did not differ between cases and controls. Fatty acids did not correlate with the years of storage except for lauric acid that increased up to 2-fold in the oldest samples ($p<0.001$) in cases as well as in controls. There was no significant correlation between metabolite concentrations and age at diagnosis or maternal age in the case group.
Conclusion: Although storage time and conditions are critical in metabolomics studies for the potential confounding effects of lipolysis and proteolysis on the metabolites, our samples from carefully matched cases and controls enabled the use of older samples. In our study the metabolite pattern at birth distinguished children who developed type 1 diabetes from the matched control children who remained healthy. The evidence of these early metabolic alterations may give new insights into type 1 diabetes early pathogenesis and identify potential triggering factor of islet autoimmunity possibly involving gestational events. The identification and validation of key metabolites marking the progression to islet autoimmunity and clinical onset may also provide new markers for disease prediction.

GAD65- and (pro)insulin-specific CD4+ T cells detected by MHC class II tetramers in diabetes-associated autoimmunity

V. Öling[1], H. Reijonen[2], O. Simell[3], M. Knip[4,5], J. Ilonen[1,6];
[1]Immunogenetics Laboratory, University of Turku, Finland, [2]Benaroya Research Institute at Virginia Mason, Seattle, USA, [3]Department of Paediatrics, University of Turku, [4]Hospital for Children and Adolescents and Folkhälsan Research Center, University of Helsinki, [5]Department of Paediatrics, Tampere University Hospital, [6]Department of Clinical Microbiology, University of Eastern Finland, Kuopio, Finland.

Background and aims: Autoreactive CD4+ T cells contribute to the destruction of insulin producing beta-cells in type 1 diabetes (T1D). The aim of this study was to investigate the frequency of circulating GAD65-, proinsulin- and insulin-specific CD4+ T cells during the pre-clinical phase of T1D and to evaluate the naïve/memory phenotype of these autoreactive T cells.
Materials and methods: Using MHC class II tetramers, we have analysed the frequency of GAD65- (274-286 and 555-567 557I), proinsulin- (B24-36) and insulin- (A1-15 and A6-21) specific CD4+ T cells in 26 children with recently diagnosed T1D, 48 multiple autoantibody-positive children and 70 HLA- and age-matched control children. In a smaller group of children memory and naïve T-cell responses to the same autoantigens were investigated as well.
Results: We observed that the children with multiple autoantibodies recognize the GAD65 555-567 (557I) peptide more frequently (52.4%) than the children with T1D (22.2%) or controls (30.5%) (P=0.027). Furthermore, multiple autoantibody-positive children had more often memory (CD45RO+) T cells specific for GAD65 555-567 compared to controls (P=0.028), in whom none (n=27) displayed a positive memory T-cell response to this peptide. Interestingly, in children with T1D GAD65 555-567 specific T cells were both memory and naïve, (P=0.029 and 0.044, in comparison to controls, respectively). The other investigated peptides were frequently recognized in the study population, but no statistically significant differences were observed.
Conclusion: These results indicate a higher CD4+ T-cell reactivity to the GAD65 555-567 epitope in children with recently diagnosed T1D and in multiple autoantibody-positive children compared to unaffected controls testing negative for autoantibodies.

264

Novel triples mix radio binding assay for the ZnT8 (ZnT8RWQ) autoantibody variants in children with newly diagnosed diabetes

F. Vaziri-Sani[1], A.J. Delli[1], H.E. Larsson[1], B. Lindblad[2], A. Carlsson[3], G. Forsander[2], S.A. Ivarsson[1], J. Ludvigsson[4], C. Marcus[5], Å. Lernmark[1]; [1]Department of Clinical Sciences, Lund University, Malmö, [2]Department of Pediatrics, The Queen Silvia Children's Hospital, Göteborg, [3]Department of Pediatrics, Lund University, [4]Linköping University Hospital, Department of Clinical and Experimental Medicine, [5]Department of Pediatrics, Karolinska University Hospital, Huddinge, Sweden.

Background and aims: Autoantibodies (A) against the ZnT8 transporter are common in type 1 diabetes. The ZnT8A analyses are complicated by the fact that it is not only one but three autoantigens representing ZnT8R (arginine), ZnT8W (tryptophan) and ZnT8Q (glutamin) at amino acid position 325. It is important to detect all ZnT8A variants not only to predict type 1 diabetes but also to select subjects for prevention and intervention clinical trials. The aims were: 1) to develop an autoantigen triple mix Radio-Binding Assay (RBA) to screen for ZnT8A; 2) to identify the individual ZnT8-RWQA reactivity and 3) to validate the triple mix ZnT8Ab RBA in children with newly diagnosed type 1 diabetes.
Materials and methods: Serum or plasma samples were obtained from 1868 patients in the on-going Better Diabetes Diagnosis (BDD) study. BDD is a nationwide prospective cohort study that involves newly diagnosed diabetes children who are <18 years from 40 (95%) pediatric clinics in Sweden. The cDNA coding for the C-terminal end of each variant was subcloned into the high efficiency *in vitro* transcription translation pTNT vector (Promega, Madison, WI, USA) following site-directed mutagenesis. The ZnT8 variants were labelled with 35S-methionine and used at 425 cpm/μL in standard RBA separating free from autoantibody-bound autoantigen with Protein A-Sepharose. All samples were first analyzed for autoantibodies to each individual variant of ZnT8. Bound radioactivity was converted into in-house units using a standard curve generated negative controls and by a type 1 diabetes serum standard with high reactivity for each of the ZnT8R, ZnT8W and ZnT8Q antigens. All samples were also analyzed in a triple mix RBA to detect all three variants (ZnT8-RWQA) simultaneously. The ZnT8-RWQA RBA was performed after the three variants were mixed at a final concentration of 425±25 cpm/μL. The bound radioactivity were converted into in-house units using negative controls and a type 1 diabetes serum standard with high reactivity for all three ZnT8A variants.
Results: We examined sera from 1868 (53% males) newly diagnosed incident type 1 diabetes patients <18 years who were registered in the BDD study. ZnT8-RA was detected in 964 (52%) patients, ZnT8-WA in 895 (48%) and ZnT8-QA in 609 (33%). Autoantibodies to all three variants were found in 527 (28%) patients. ZnT8-RWQA was detected in 1267 (68%) patients representing only 5.6% false positive samples. None of the new-onset patients was false negative for ZnT8-RWQA. The highest ZnT8A frequencies were found among the 5-9 (67%) and 10-14 (72%) year old patients. Neither the ZnT8-RWQA nor the three individual variants showed gender variation.
Conclusion: The major finding in this study was that the ZnT8A triple mix assay had a low false positive rate and a negligible false negative rate. The ZnT8A triple mix assay would therefore be highly suitable for screening the general population, as it is likely not to miss individuals who have anyone of the three variants.

Differences in thrombotic and inflammatory markers comparing subjects with maturity onset diabetes of the young and type 2 diabetes

M.J. Bottomley[1], G. Thanabalasingham[2], K. Hess[1], K.R. Owen[2], R.A. Ajjan[1]; [1]Leeds Institute of Genetics, Health and Therapeutics, Leeds, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom.

Background and aims: Mutations in the Hepatocyte Nuclear Factor 1α (*HNF1A*) gene are the commonest cause of Maturity onset diabetes of the young (MODY) in the UK, characterised by β-cell dysfunction without insulin resistance. Cardiovascular disease is the main cause of mortality in individuals with diabetes and it has been demonstrated that fibrin network structure and its resistance to lysis determines predisposition to atherothrombotic disease. The aim of this work was to investigate clot structure/fibrinolysis and cardiovascular inflammatory markers in subjects with HNF1A-MODY and type 2 diabetes (T2DM).
Materials and methods: Subjects with HNF1A-MODY (n=18, mean age 35.3 years, 11 female) and T2DM (n=12, mean age 43.3 years, 8 female) were recruited. Fibrin clot structure was measured using a validated turbidimetric assay; clot final turbidity, a measure of clot density and time from full clot formation to 50% lysis, an indicator of lysis potential, were recorded. Plasma fibrinogen, plasminogen activator inhibitor-1 (PAI-1) and the cardiovascular inflammatory proteins complement-3 (C3) and C-reactive protein (CRP) were also measured by ELISA. All values are given mean±SEM.
Results: The groups did not significantly differ in age, gender, insulin use, blood pressure, HbA1c or BMI. The HNF1A-MODY group recorded lower final turbidity compared with T2DM (0.33±0.13 vs 0.44±0.12 au respectively, p=0.03). Time from full clot formation to 50% lysis was shorter in the HNF1A-MODY group than T2DM (473±159 vs 588±199s, p=0.048). Despite differences in final turbidity and lysis time, fibrinogen levels were similar (2.8±0.7 vs 2.9±0.5g/L, p=0.6), as were PAI-1 levels (1.99±1.27 vs 1.65±0.82ng/ml, p=0.47). C3 levels were significantly lower in HNF1A-MODY subjects than T2DM (0.58±0.20 vs 0.80±0.21mg/ml, p=0.006), whereas CRP was not different (1.16±2.07 vs 1.85±1.09 mg/L, p=0.3). C3, a protein known to be incorporated into the fibrin network, correlated strongly with final turbidity (r= 0.66, <0.001) and time to 50% lysis (r=0.7, p<0.001).
Conclusion: Our data suggest that, despite phenotypic similarities between the groups, those with T2DM have tighter clot structure, which is more resistant to fibrinolysis compared with HNF1A-MODY. The similar plasma levels of fibrinogen and PAI-1 suggests this is due to post-translational modifications in the fibrinogen molecule or other, yet unidentified, plasma factors. One possible explanation may be related to higher C3 plasma levels in T2DM patients, directly affecting clot structure and lysis time. Taken together, our data suggest that patients with HNF1A-MODY are at lower risk of macrovascular diabetic complications than matched T2DM patients.

A large part of the MODY patients in Slovakia do not have any mutation in GCK, HNF1A, HNF4A, HNF1B, KCNJ11 or insulin genes

D. Gasperikova[1], J. Stanik[1,2], M. Huckova[1], L. Valentinova[1], I. Masindova[1], D. Lesayova[1,3], L. Barak[2], M. Kusekova[4], V. Sandrikova[5], J. Javorkova[6], J. Michalek[7], Slovak MODY Collaborative Study Group, I. Klimes[1]; [1]DIABGENE, Institute of Experimental Endocrinology, Bratislava, [2]Children Diabetes Center, 1st Dept. of Pediactrics, Comenius University, Bratislava, [3]1st Dept. of Pediatrics, Children University Hospital, Bratislava, [4]1st Dept. of Pediatrics, P.J Safarik University, Kosice, [5]Outpatient Children Endocrinology Clinic, Prievidza, [6]Dept. of Pediatrics, Jessenius Medical School, Comenius University, Martin, [7]National Inst. of Diabetes and Endocrinology, Lubochna, Slovakia.

Introduction: Maturity Onset Diabetes of the Young (MODY) is a heterogenous group of monogenic diabetes with early onset, familiar appearance, and autosomal dominant inheritance. MODY could be caused by a mutation in one of the nine MODY genes, or genes causing predominantly neonatal diabetes. Nevertheless, large number of MODY families does not have any mutation in the genes so far identified. Patients with clear phenotype of MODY diabetes without one of the known mutation, are thus labelled as MODY-X subjects.

Aim: Of this study was to identify the genetic background of families, fulfilling the MODY clinical criteria, and to calculate the frequency of selected MODY subtypes and MODY-X in Slovakia.
Methods: 239 patients from 97 families fulfilling the MODY clinical diagnostic criteria (Ellard et al, 2008), were actively identified in the diabetes outpatient clinics throughout Slovakia. The relevant genes responsible for MODY (*GCK, HNF1A, HNF1B, HNF4A, KCNJ11* and *insulin*) were analyzed using the direct sequencing technique and MLPA.
Results: 152 patients from 57 families had 35 different mutations in one of the target genes: 33 probands and 65 family relatives had a mutation in *GCK* gene; 22 probands and 29 their family relatives had a mutation in *HNF1A* gene; one family (2 pts) had a mutation in the *HNF4A* gene, and one proband had a *HNF1B* whole gene deletion. No *KCNJ11* and *insulin* gene mutation carriers were found.
Conclusion: Out of 97 families, 40 families had no mutation in the genes analyzed. Among the MODY subtypes, the most prevalent are the *GCK* mutations (34% of MODY), followed by *HNF1A* (23%), *HNF4A* (1%) and *HNF1B* (1%) mutations. Despite of DNA analysis of the six MODY genes, the MODY-X families account up to 41% of all cases. The latter is a great challenge for identification of further genes leading to MODY diabetes.

Liver adenomatosis in MODY 3 diabetes mellitus families: screening 174 patients
A. Rod[1], C. Bellanne-Chantelot[2], PHRC MODY 3 and Liver Adenomatosis Study Group, L. Chiche[3], Y. Reznik[1];
[1]Service d'endocrinologie - diabétologie, CHU Côte de nacre, Caen, [2]Laboratoire de génétique des maladies métaboliques, CH La Pitié Salpetrière, Paris, [3]Service de chirurgie digestive et hépato-biliaire, CHU Côte de nacre, Caen, France.

Background and aims: Liver adenomatosis is a rare disorder susceptible to hemorrhagic complication and rarely malignant transformation. Liver adenomatosis results from the biallelic inactivation of the HNF1A gene which encodes a transcriptional factor.The epidemiology of the disease is poorly documented. The aim of this study was to evaluate the frequency of liver adenomatosis in a population of MODY 3 patients carrying a HNF1A germinal mutation, and to describe the clinical course of the disease in the patients affected by the liver disease.
Materials and methods: 174 patients from 74 families MODY 3 were included in 13 French centres. Screening for liver adenomatosis was performed by systematic liver ultrasonography. When the disease was suspected, liver CT or MRI was performed for confirmation of the diagnosis. Histopathological analysis was performed when a surgery was mandatory.
Results: Among 137 patients carrying an HNF1A mutation, 9 cases of liver adenomatosis were identified in 7 different families. Mutations were spread all over the coding region of the HNF1A gene. Patients mean age was 32,8 years (11-56), the M/F sex ratio was 2/7, 7/9 patients had diabetes mellitus, the two remaining patien ts were children presently normoglycemic. Liver imaging showed adenomas of various sizes from less than ten mm (1/9), to larger lesions (8/9) up to 120 mm. Liver biology was near normal in all patients. One case of adenomatosis was revealed by two episodes of internal hemorrhage. Five women had ten pregnancies without any complication nor progression of the adenoma size. Histopathological confirmation of liver adenomatosis was available in five patients, and all adenomas were steatotic at variable degree.
Conclusion: The frequency of liver adenomatosis in this cohort of MODY 3 diabetic patients (6,5%) and the risk for hemorrhagic complication of the disease favours the systematic screening for liver adenomatosis in MODY 3 families.

Hypomagnesaemia revealing Maturity Onset Diabetes of the Young (MODY) type 5 linked to TCF2 mutation
D. Quintin[1], A.-S. Balavoine[1], C. Hober[2], L. Heidet[3], C. Antignac[3], R. Vargas-Poussou[4], M.-C. Vantyghem[1];
[1]Endocrinology and Metabolism, Lille University Hospital, [2]Endocrinology and Metabolism, Henin-Beaumont Hospital, [3]Genetic Departments, Necker-Enfant Malades Hospital, Paris, [4]Genetic Departments, European Hospital G Pompidou, Paris, France.

Two to 5% of non insulin dependent diabetes (NIDD) are related to ß cell genetic anomalies among which six types of Maturity Onset Diabetes of the Young (MODY), linked respectively to mutations of genes encoding 1) HNF-4alpha, 2) GCK, 3) HNF-1alpha, 4) IPF-1, 5) the transcription factor HNF-1ß (encoded by *TCF2*) and 6) NeuroD1/ß2. A 34 year-old woman was referred for uneasiness with tremor and paresthesia. Hypertension was present in her two parents. Her own medical history was marked by 4 episodes of seizures at 8 months one of them related to hypocalcemia (60mg/l; Normal range (N): 95-105) with otherwise negative etiological investigations except fever in another episode. She developed mild mental retardation without dysmorphic features, and was regularly menstruated. NIDD was discovered at 18 years old. At 34 years old, her BMI was 25 and her blood pressure 130/80 mmHg with normal clinical examination. Biological investigations without treatment showed severe hypomagnesemia (12 mg/l; N: 18-20) by renal wasting (152 mg/24h; N: 80-180), with calciuria between 72 and 130 mg/24h; N:100-250) with normal blood creatinine (10mg/l), potassium (4.1mmol/l), calcium (96 mg/l), HCO3- (28 mmol/l), PTH (34 pg/ml), 25 OH vitamin D (50 nmol/l; N:25-150), renin and aldosterone levels. There was nor proteinuria, microalbuminuria, neither sediment anomalies. The NIDD was characterized by normal blood C-peptide level (2.2 ng/ml (N: 0.5-2, neutral HLAdq susceptibility for type 1 diabetes and undetectable islet auto-antibodies. HbA1c was 7.2% (N<6.5). Intravenous glucose tolerance test performed with and without intravenous magnesium repletion, showed high insulinemia when blood magnesium levels were low, arguing for severe insulin resistance (insulinemia 200 to 250 mU/l), corrected by magnesium repletion (insulinemia 10 to 15 mUI/l) for similar blood glucose levels (reaching 3,5g/l). Kidney cysts, hypertension and increased liver enzyme levels (TGO 109, TGP 218; n<40 UI/l) occurred with time. Genetic investigation showed a heterozygous deletion of the 9 exons of *TCF2* gene, which was identified nor in 2 of her 3 living brothers and sisters (one was dead). To conclude, mild low magnesium level has been reported in NIDD. Nevertheless the severity of hypomagnesemia linked to renal wasting suggested a tubulopathy. Early occurrence of hypomagnesemia with hypocalcemia was compatible with *TRPM6* mutations, whereas isolated hypomagnesemia are associated with mutations of *pro-EGF* (with often mental retardation) or gamma sub-unit of Na-K ATPase. Finally, genetically determined diabetes with hypomagnesemia can be linked to mitochondrial cytopathy or *TCF2* mutations. The presence of renal cysts suggested this last diagnosis, even if in MODY 5, hypomagnesemia is rarely so severe. In this situation low magnesium levels are probably explained by the regulation of FXYD2 transcription, which participates to magnesium tubular reabsorption, by HNF 1ß.

Genetic counselling for MODY, MIDD and other type of diabetes mellitus
N. Iwasaki[1,2], M. Takizawa[1], R. Fujimaki[1], M. Ogata[1], K. Saito[2], Y. Iwamoto[1];
[1]Diabetes Center, [2]Institute of Medical Genetics, Tokyo Women's Medical University, Tokyo, Japan.

Background and aims: Recently, genetic testing is provided in the clinical practice of diabetes mellitus. We have started the genetic counseling for diabetes since May 2006, however, such medical service is still few and no report has been published in Japan. The aim of this study is to clarify the current status of genetic testing for diabetes and evaluate the quality of genetic counseling by a hospital based setting.
Materials and methods: We reviewed the medical records of the cases who received genetic counseling for diabetes in the Institute of Medical Genetics at Tokyo Women's Medical University from May 2006 to March 2010. The number of such proband was 22. After informed consent was obtained from the patients, the screening for mutations in the candidate genes had done at the Diabetes Center and other academic institute according to the disease.

Results: Two patients were self referral and 20 were referred by other physicians. Ten patients had been diagnosed with mitochondrial diabetes (MIDD) including mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke (MELAS) syndrome, 8 patients with maturity-onset diabetes of the young (MODY), one with early onset type 2 diabetes having renal hypoplasia, one with diabetes insipidus, diabetes mellitus, optic atrophy and deafness (DIDMOAD) or Wolfram syndrome, one with type 2 diabetes and cardiac myopathy, and one with just type 2 diabetes. We found 4 cases with mutations in the HNF-1a/MODY3 gene among 7 cases of MODY (57%) who received the genetic testing; two cases with P291fsinsC, one with R200W and one with P379S (CCT>TCT). A subject with renal hypoplasia but lacking family history of diabetes showed a large deletion at chromosome 17q12 including HNF-1b/MODY5 gene. Among 8 cases with MIDD, 6 cases were positive for 3243 A>G mutation in the mitochondrial gene. Subjects with DIDMOAD had found to have compound heterozygous mutation in the exon 8 of wolfram 1 gene (L468X, del509VYLLY). Genetic testing for three patients with MIDD/MELAS and one with MODY had been carried out at other institutions. They had not received appropriate counseling regarding the nature of their condition and visited our clinic to obtain more information regarding the results of the genetic testing.
Conclusion: Our study indicates that 1) a need of the genetic counseling for diabetes exists in Japan, 2) MODY3 is prevalent among MODY in our institute, 3) patients should receive genetic counseling and psychological evaluation before any genetic testing are carried out.

Insulin sensitivity in children with permanent neonatal diabetes mellitus treated with sulfonylurea
A. Szadkowska, I. Pietrzak, A. Gach, B. Mianowska, W. Fendler, W. Młynarski;
Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Poland.

Background and aims: Adults with permanent neonatal diabetes mellitus (PNDM), carriers of a Kir6.2 mutation were characterized by decreased insulin sensitivity. The transfer to sulphonylurea therapy improved insulin sensitivity in them. Aim of the study was to estimate insulin sensitivity in PNDM children with Kir6.2 mutation during insulin therapy and after their transfer to sulfonylurea.
Materials and methods: Three children aged 9, 11, 14 years with diabetes mellitus recognized in the first 6 months of life with confirmed Kir6.2-activating mutations were included into the study. Euglycemic-hyperinsulinemic clamp was performed to estimate insulin sensitivity. Glucose disposal rate (M value) determined during the last 30 min of the test was calculated as a surrogate of insulin resistance. The height, weight were measured and body mass index (BMI) was calculated. HbA1c was measured by HPLC. All examinations were performed on insulin therapy and 6 months after transfer to sulphonylurea.
Results: Baseline M values in children were: 15,0; 7,25 and 13,33 mg · kg^{-1} · min^{-1}, (mean 11,86±4,08). The mean BMI was 15,27±1,10 kg· m^{-2} and HbA1c was 6,93±0,38%. Six months after the initiation of sulfonylurea therapy we did not observe significant reduction of body weight (Δ BMI = - 0,46±0,54; p=0,28). The improvement in metabolic control was noted (Δ HbA1c = - 1,03±0,25%; p=0,02). A substantial improvement in insulin sensitivity was found in all examined patients. Mean decrease in M value (Δ M) was 2,92±1,88 mg · kg^{-1} · min^{-1} (p=0,11). After adjusting to BMI and HbA1c Δ M value was -1,21±1,52 mg · kg^{-1} · min^{-1} (p=0,33).
Conclusion: In PNDM children insulin resistance was not observed during insulin therapy. A slight improvement of insulin sensitivity was noted after initiation of sulphonylurea therapy, but it was influenced by improvement of metabolic control.

271

The first case report of sulphonylurea use in a woman with PNDM due to KCNJ11 mutation during a high risk pregnancy
E. Kozek[1], T. Klupa[1], N. Nowak[1], K. Cyganek[1], A. Gach[2], T. Milewicz[3], K. Czajkowski[4], J. Tolloczko[5], W. Mlynarski[6], M.T. Malecki[1];
[1]Department of Metabolic Diseases, Jagiellonian University, Krakow, [2]Department of Genetics, Polish Mother's Memorial Hospital, Lodz, [3]Department of Gynecological Endocrinology, Jagiellonian University Medical College, [4]2nd Department of Obstetrics and Gynecology, Warsaw Medical University, [5]Department of Neonatology and Neonatal Intensive Care, Warsaw Medical University, [6]Department of Genetics, Polish Mother's Memorial Hospital, Poland.

Background and aims: Sulphonylureas (SU) were proven to be more effective than insulin in most KCNJ11 gene (encoding Kir6.2) related Permanent Neonatal Diabetes Mellitus (PNDM) patients. So far, there was no data on SU use in pregnancy in a KCNJ11 mutation carrier. Here, for the first time, we report SU use in a woman with PNDM due to the KCNJ11 mutation during a high-risk pregnancy.
Materials and methods: A woman with the R201H Kir6.2 mutation became pregnant at the age of 37. The patient had been on glipizide 30 mg for 3 years; her HbA1c level was 5.8%. She was diagnosed with chronic diabetes complications and a congenital defect of urogenitary tract- a bicornuate uterus with septum. As the effect of SU on fetal development is uncertain, she was switched to insulin after the pregnancy diagnosis, however, the subsequent glycemic control was unsatisfactory, with episodes of hyper- and hypoglycemia. Thus, in the 2nd trimester, the patient was transferred to SU (glibenclamide 40 mg).
Results: Transfer to glibenclamide resulted in stabilization of glycemic control; HbA1c in the 3rd trimester was 5.8%. The prenatal genetic testing excluded the Kir6.2 R201H mutation in the fetus. The preterm Cesarian delivery was carried out in the 35th week due to cardiotocography abnormalities. The Apgar score of the newborn boy (weight 3010g, 75th percentile) was 8 at 1 min. He presented with hypoglycemia, transient tachypnea of the newborn (TTN), and hyperbilirubinemia. The recovery was uneventful. No birth defects were recorded. His development at the 9th month of life was normal.
Conclusion: We show a high-risk pregnancy in long-term PNDM that in spite of perinatal complications ended with the birth of a healthy child. SU, that seem to constitute an alternative to insulin during pregnancy in Kir6.2 related PNDM, were used during the conception period and most of the 2nd and 3rd trimester. Prenatal molecular testing should be considered in pregnant women with PNDM especially when other medical indications for amniocentesis, like older age of the mother, are present.

Diabetes onset among carriers of the WFS1 gene mutation in the families with Wolfram syndrome
A. Zmyslowska, M. Borowiec, K. Wyka, K. Antosik, A. Szadkowska, I. Pietrzak, W. Mlynarski;
Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Poland.

Background and aims: Wolfram syndrome is a rare form of diabetes mellitus associated with an optic atrophy and disorders of different organs e.g. deafness, endocrinologic, neurologic and hematologic abnormalities. This syndrome is caused by the mutations in wolframin gene localized on chromosome 4p16.1 (*WFS1*). Wolfram syndrome is inherited as an autosomal recessive trait. The aim of the study was an evaluation of the clinical course of this syndrome and the mutations in the *WFS1* gene in the Polish patients.
Materials and methods: 9 patients with the clinical symptoms suggesting Wolfram syndrome (at least diabetes mellitus and optic atrophy) aged: 10-24, mean 15.4±4.9 years and 22 first-degree relatives aged: 3-50, mean 27.8±15.7 years were examined. The genetic analysis was carried out by direct DNA sequencing of *WFS1* gene. Additionally, a cosanquinity evaluation using the multiplex-PCR method at16 polymorphic loci was performed.
Results: In 9 patients with Wolfram syndrome nine mutations in *WFS1* gene were identified. In the patients the mean age of diagnosis of diabetes mellitus was 5.6±1.8 years. Six patients were homozygous for the following mutations: V412fs, S443R, W539X, V659fs. They developed diabetes at the age of 5, 5, 4, 4, 5 and 8 years, respectively. Three patients were complex heterozygous for the following mutations: S167fs, Q392X, Y513fs, W648X, V779G. They

developed diabetes at age of 8.8, 7 and 3.8 years, respectively. Among different nine mutations five - S167del, S443R, Q392X, Y513fs, W539X were novel. Among first-degree relatives 17 individuals were heterozygotic carriers of the mutation. In this group no clinical symptoms characteristic for Wolfram syndrome were noticed and none of these carriers had diabetes (age at examination: 34.2±16.1 yrs).
Conclusion: Mean age of diagnosis of diabetes among the Polish patients was typical for Wolfram syndrome, however, complex heterozygous patients were slightly older at diabetes onset. Interestingly, none of the heterozygotic carriers of *WFS1* mutation suffered from diabetes, which is in contrary with the results from the whole genome association studies suggesting that some common SNPs in *WFS1* may predispose to type 2 diabetes.

PS 2 Genetics of type 1 diabetes

273

Clinical and genetical characterisation of a series of patients with type 1 diabetes induced by interferon therapy
K. Nakanishi[1,2];
[1]Dept. of Endocrinology and Metabolism, Okinaka Memorial Institute for Medical Research, Tokyo, [2]Dept. of Internal Medicine, Fuji-Toranomon Hospital, Gotemba, Japan.

Background and aims: Interferon alpha is widely used for treatment of several diseases including chronic hepatitis C, and rarely causes type 1 diabetes. The aim of this study is to clarify clinical and genetical characteristics of interferon-induced type 1 diabetes.
Materials and methods: Subjects were consecutive 12 patients in whom type 1 diabetes occurred after interferon therapy due to chronic hepatitis C during 1998-2009. To compare clinical pictures, 128 patients with type 1A diabetes who had at least one data about anti-GAD65 antibodies or serum fasting C-peptide levels during first 4 years were enrolled. As genetic controls, 10 patients in whom diabetes did not develop after interferon therapy due to chronic hepatitis C were enrolled. In addition, 136 normal control subjects were enrolled. GAD antibodies were assayed by radioligand binding assay, and C-peptide was measured by sensitive radioimmunoassay. HLA-A, -DRB, -DQA and -DQB alleles were typed by PCR-RFLP methods.
Results: Ten of 12 (83.3%) patients with interferon-induced type 1 diabetes showed ketosis at the onset and 11 of 12 (91.7%) needed insulin therapy within 3 months after the onset of diabetes. Titer of GAD antibodies were higher in the patients with interferon-induced type 1 diabetes than those with type 1A diabetes at the onset [median (range): 3,309 (15-110,000) vs. 7.7 (<1.2-38,000) U/ml, p<0.0001], at 1year [347 (31-10,000) vs. 1.6 (<1.2-3,194) U/ml, p=0.0041], and at 2-4 years [1,248 (37.6-6,379) vs. 3.5 (<1.2-6,514) U/ml, p=0.0002] after the onset of diabetes. Levels of fasting serum C-peptide were higher in the patients with interferon-induced type 1 diabetes than those with type 1A diabetes at the onset (0.42 ± 0.27 vs. 0.25 ± 0.24 nmol/l, mean ± SD, p=0.016), at 1year (0.49 ± 0.24 vs. 0.23 ± 0.23 nmol/l, p=0.0015) and at 2-4 years (0.37 ± 0.32 vs. 0.13 ± 0.15 nmol/l, p=0.018) after the onset of diabetes. Insulin dose was not different at the onset (0.37 ± 0.21 vs. 0.47 ± 0.20 U/kg/day, p=0.12), but lower at 1year (0.30 ± 0.19 vs. 0.59 ± 0.14 U/kg/day, p=0.0007) and at 2-4 years (0.41 ± 0.25 vs. 0.59 ± 0.21 U/kg/day, p=0.029) after the onset of diabetes in the patients with interferon-induced type 1 diabetes than those with type 1A diabetes, while mean HbA_{1c} levels during first 5 years were not different between 2 groups (7.07 ± 0.97 vs. 7.48 ± 1.38%, p=0.51). Allele frequency of HLA-A*2402 was increased in patients with interferon-induced type 1 diabetes compared with those who did not develop diabetes despite interferon therapy [50.0% (12/24) vs. 20.0 % (4/20), odds ratio (OR) (95% confidence interval (CI)): 4.00 (1.09-17.26)]. Although frequency of other HLA-A alleles and DR-DQ haplotypes did not differ between these two groups, phenotypic frequency of DRB1*1302-DQA1*0102-DQB1*0604 was increased in these two groups combined [59.9% (13/22)] compared with normal controls [16.2% (22/136), OR (95%CI): 7.48 (2.89-20.27)], and those with type 1A diabetes [9.7% (10/103), OR (95%CI): 13.4 (4.72-40.96)].
Conclusion: Despite acute-onset form, interferon-induced type 1 diabetes was characterized by prolonged high titers of GAD antibodies, relatively preserved residual beta cell function, and subsequently lesser dose of insulin required. Addition of HLA-A*2402 to specific HLA class II background (DRB1*1302-DQA1*0102-DQB1*0604) may confer susceptibility to type 1 diabetes induced by interferon therapy.

274

The frequency of ZnT8 autoantibodies and their HLA associations differ between Swedish and immigrant children with newly diagnosed type 1 diabetes in the Better Diabetes Diagnosis Study
A.J. Delli[1], F. Vaziri-Sani[1], A. Carlsson[2], G. Forsander[3], S.A. Ivarsson[1], B. Lindblad[3], J. Ludvigsson[4], C. Marcus[5], Å. Lernmark[1];
[1]Department of Clinical Sciences, Lund University, Malmö, [2]Department of Pediatrics, Lund University Hospital, [3]Department of Pediatrics, The Queen Silvia Children's Hospital, Göteborg, [4]Department of Clinical and Experimental Medicine, Linköping University Hospital, [5]Department of Pediatrics, Karolinska University Hospital, Huddinge, Stockholm, Sweden.

Background and aims: The ZnT8 autoantibodies (ZnT8A) are assuming an increasing importance in the prediction and diagnosis of childhood type 1 di-

abetes (T1D). The fact that single amino acid polymorphism at position 325 of ZnT8 identifies three antigenic variants: Argenine (ZnT8-R), Tryptophan (ZnT8-W) or Glutamine (ZnT8-Q); highlights the importance of ZnT8A in T1D. The type and frequency of autoantibodies against ZnT8 variants and their associations with the HLA class II DQ genes among different ethnic entities were not previously investigated. Our aim was to determine the relation between ethnic origin of the patient and the detection of ZnT8A in relation to high-risk HLA DQ genotypes and conventional islet autoantibodies (GAD65A, IA-2A and IAA) in Sweden.
Materials and methods: A total of 1868 (53% males) newly diagnosed T1D children <18 years at onset were recruited from the Better Diabetes Diagnosis (BDD) study during the period from May 2005 to September 2008. This cohort was grouped into three subgroups based on the origin of patients defined by country of birth of their parents and grandparents into Swedes (67%), non-Swedes (8%) and mixed-origin (16%) with 9% were of uncertain origins. Chi square test of independence was used to detect significant differences among ethnic groups in relation to ZnT8A variants and HLA and other islet autoantibodies. Logistic regression models were used to assess a possible association between nine high-risk HLA DQ genotypes and ZnT8A among ethnic groups.
Results: A total of 964 (52%) tested positive for ZnT8RA, 895 (48%) for ZnT8WA and only 609 (33%) for ZnT8QA. Among the same cohort, 1338 (72%) patients were positive for IA-2A, 1052 (56%) for GAD65A and 587 (31%) for IAA. In total only 126 (7%) patients were negative for all six autoantibodies. Nine HLA DQ genotypes were identified as high risk genotypes among the BDD patients compared to the Swedish general population. Only the ZnT8WA variant was significantly higher among Swedes (49%) compared to non-Swedes (39%) ($p<0.02$). Among Swedes ZnT8WA was associated with DQ8/8 ($p<0.009$) and DQ8/6.4 ($p<0.001$) genotypes while ZnT8RA and ZnT8QA were associated only with DQ8/6.4 genotype ($p<0.009$ and $p<0.007$ respectively). However, the DQ2 haplotype but not the DQ2/2 genotype was negatively associated with ZnT8RA and ZnT8QA variants among Swedes ($p<0.008$ and $p<0.005$ respectively) but not the ZnT8WA variant. Among non-Swedes none of these genotypes showed an association with any of the three ZnT8A variants. On the other hand, among Swedes both IA-2A and GAD65A were associated with all the three variants of ZnT8A. However, among non-Swedes only IA-2A showed associations with ZnT8RA and ZnT-8WA but not ZnT8QA (p values are not shown).
Conclusion: The DQ8/6.4 genotype and specifically the DQ6.4 haplotype are associated with ZnT8A among Swedish patients with T1D. Immigrant patients; however, develop ZnT8A in association with IA-2A but they may have different genetic associations from Swedish patients.

Novel type 1 and type 2 diabetes susceptibility genes influence development of islet autoimmunity and type 1 diabetes in children of parents with type 1 diabetes
C. Winkler[1], E. Bonifacio[2], H. Grallert[3], C. Lauber[1], E. Trovesi[2], T. Illig[3], A.-G. Ziegler[1,4];
[1]Institut fuer Diabetesforschung der Forschergruppe Diabetes e.V. at Helmholtz Center Munich, Neuherberg, [2]Center for Regenerative Therapies - Dresden University of Technology, [3]Institute of Epidemiology, Helmholtz Center Munich, Neuherberg, [4]Forschergruppe Diabetes der Technischen Universitaet Muenchen, Germany.

Background and aims: Type 1 Diabetes (T1D) is an autoimmune disease with multiple susceptibility genes. It has been suggested that T1D and type 2 diabetes (T2D) may share some pathophysiological and genetic aetiology. The aim was to investigate whether novel T1D and T2D suceptibility genes influence development of islet autoimmunity and/or progression from islet autoimmunity to T1D.
Materials and methods: The single nucleotide polymorphisms (SNPs) in 6 T1D associated gene regions (*PTPN22, ERBB3, PTPN2, KIAA0350, CD25, IFIH1*) and 9 T2D associated gene regions (*KCNJ11, PPARG, TCF7L2, SLC30A8, CDKAL1, CDKN2A/2B, HHEX-IDE, IGF2BP2, FTO*) were analyzed in 1350 children from the German BABYDIAB study, a prospective observational study that follows offspring of mothers or fathers with T1D from birth to adulthood. A total of 137 children developed at least one persistent islet autoantibody [median age at first islet autoantibody appearance 4.9 (IQR 2.0-8.1)]; and 43 of these children progressed to T1D [median age at diagnosis 11.9 (IQR 9.4-14.9)].
Results: The T2D protective *TCF7L2* TT genotype was associated with a significantly higher incidence of islet autoimmunity than the CT and CC genotype (12% vs. 7% by age of 10 years, p=0.012). After stratification of the HLA genotype the *TCF7L2* TT genotype was associated with a significantly higher incidence of islet autoimmunity than the CT and CC genotype in children carrying the moderate/neutrale/protective HLA genotypes (10% vs. 5% by age 10 years p=0.006) but not in children carrying the high risk HLA genotypes (DR3/4 or DR4/4) (p=0.483). None of the other T1D and T2D susceptibility genes were associated with the development of islet autoimmunity in our cohort. Amongst the islet autoantibody positive children, progression to T1D was increased in children with the T1D susceptible *IFIH1* GG genotype (47% within 10 years after seroconversion vs. 32% in children with the GA and AA genotypes; OR: 1.9, p=0.01), children with the T1D susceptible *PTPN22* AA genotype (OR: 15.9, 95%CI: 1.6-160.4; p=0.001 vs CA and CC genotypes), children with the T2D susceptible *SLC30A8* CC genotype (OR: 2.4, 95%CI: 1.2-4.8; p=0.015 vs CT and TT genotypes), and children with the T2D susceptible *FTO* AA genotype (OR: 2.4, 95%CI: 1.1-5.4; p=0.031 vs CA and CC genotypes).
Conclusion: These data suggest that T2D susceptibility genotypes are unlikely to predispose to the development of islet autoimmunity, but that both T1D and T2D susceptibility genes may increase the rate of progression from islet autoantibody positive to diabetes.

Genetic predisposition score for obesity is associated with BMI in individuals with type 1 diabetes
E. Fagerholm[1,2], C. Forsblom[1,2], N. Sandholm[1,3], J. Söderlund[1,2], V. Harjutsalo[1], J. Wadén[1,2], N. Tolonen[1,2], M. Saraheimo[1,2], D. Gordin[1,2], L. Thorn[1,2], P.-H. Groop[1,2], on behalf of the FinnDiane Study Group;
[1]Folkhälsan Institute of Genetics, Folkhälsan Research Center, Biomedicum, Helsinki, [2]Department of Medicine, Division of Nephrology, Helsinki University Central Hospital, Helsinki, [3]Department of Biomedical Engineering and Computational Science, Helsinki University of Technology, Espoo, Finland.

Background and aims: With the help of large genome-wide association studies (GWAS) several obesity-predisposing variants have been identified. Attempts to replicate and further evaluate the association of these variants with different measures of obesity have also been carried out. The replications have been performed in different populations using both individual SNPs and genetic scores of identified SNPs. Whether the same obesity-predisposing SNPs that affect obesity in the general population affect obesity in individuals with type 1 diabetes (T1D) is not known. Therefore our aim was to study the association of obesity-predisposing SNPs with obesity in T1D using both individual SNPs and a genetic predisposition score based on the identified SNPs.
Materials and methods: All patients were part of a nationwide study of adult patients with T1D. Body mass index (BMI) and genotype data were available for 3232 individuals. 12 single nucleotide polymorphisms (SNP) in or near the following genes: *FTO*, *MC4R*, *SH2B1*, *MTCH2*, *KCTD15*, *NEGR1*, *TMEM18*, *GNPDA2*, *BDNF*, *FAIM2*, *SEC16B*, *ETV5* were used to create a genetic predisposition score for BMI. The SNPs had previously been associated with BMI in two large GWAS with BMI. The genetic predisposition score was created by calculating the number of risk alleles of the 12 SNPs for each patient. The genetic predisposition score for BMI among the patients ranged from 6 to 20. BMI was divided into three obesity categories: normal weight (BMI < 25, N=1609), overweight (BMI 25-29, N=1245) and obesity (BMI > 29, N=336).
Results: In the single SNP analyses only the SNPs located in FTO and near TMEM18 were significantly associated with BMI (P=0.0008 for FTO and P=0.01 for TMEM18) in directions consistent with prior reports. The significance persisted after adjustment for age, HbA1c and eGFR, factors known to affect BMI in T1D. While the *FTO* SNP was significant in both males (P=0.02) and females (P=0.02), the SNP near *TMEM18* was significant in males (P=0.02) but not in females (P=0.3). Although none of the other SNPs were associated with BMI, the genetic predisposition score differed significantly between the three obesity categories. Obese individuals had a genetic predisposition score of 13.1±2.0 (mean ± SD) compared to 12.8±2.0 for overweight and 12.7±1.9 for normal weight individuals (P=0.006). The score was independently associated with BMI when adjusted for factors affecting BMI in T1D (OR=1.11 [95%CI 1.04-1.19], P=0.002).
Conclusion: The obesity-predisposing SNPs in FTO and near TMEM18, originally identified in the general population, are also associated with BMI in individuals with T1D. Similarly, a genetic predisposition score of 12 obesity-predisposing SNPs was associated with BMI and obesity in T1D.

Association of type 2 diabetes genes WFS and HHEX-IDE with disease progression in children with new onset type 1 diabetes

L.B. Nielsen[1], M.-L.M. Andersen[1], J. Svensson[1], S. Pörksen[1], P. Hougaard[2], P. Swift[3], H. Hoey[4], H.B. Mortensen[1], L. Hansen[1];
[1]Pediatrics, Glostrup University Hospital, [2]Statistics, University of Southern Denmark, Odense, Denmark, [3]Leicester Royal Infirmary Children's Hospital, United Kingdom, [4]University of Dublin, Ireland.

Background and aims: Recently, several T2D related SNPs were investigated in a large T1D case-control study and PPARG and HHEX-IDE showed association with T1D. Previously we reported association of PPARG with residual beta-cell function and glycemic control during disease progression in T1D patients. The objective of this study was to investigate the impact of 11 newly identified T2D-related SNPs on disease progression in children with new onset T1D.
Materials and methods: The study is a multicenter longitudinal investigation with 18 participating paediatric centres from 15 countries in Europe (84% Caucasians). Clinical information and blood samples were collected from 275 children at diagnosis and at 1, 6, 12 months after onset. Genotyping of common SNPs in CDKAL1, WFS1, SLC30A8, CDKN2A-2B, IGFBP2, TCF7L2, FTO, HHEX-IDE, THADA was done by KBioscience using an in-house KASPar assay system. Statistics: C-peptide, HbA_{1c}, $IDAA_{1c}$ and proinsulin were analysed by multiple regression using age at onset, gender, DKA at onset, HLA class II risk groups, and genotypes as explanatory factors in a compound symmetric repeated measurement model.
Results: In a dominant model the G allele carriers (the wildtype allele) of the rs10010131 variant of the wolframin gene, WFS1, was significantly positively associated with stimulated C-peptide (est.: 1.73, p<0.0001), negatively with HbA_{1c} (est.: -0.49, p=0.005), negatively with $IDAA_{1c}$ (est.: -0.67, p=0.017) and positively with proinsulin (est.: 1.55, p=0.0045) the first 12 month after disease onset compared to the AA genotype carriers. In a co-dominant model the G allele carriers of the rs1111875 variant of the HHEX-IDE locus was significantly associated with stimulated C-peptide 12 months after disease onset compared to the AA genotype carriers in a allele dose-dependent manner (est.: 1.76 (GG), 1.30 (AG); p=0.0031).
Conclusion: The wildtype allele of the rs10010131 variant of the WFS1 gene is highly associated with a better residual beta-cell function and a corresponding better metabolic control during disease progression in new onset T1D compared to AA carriers. In addition the rs1111875 variant of the HHEX-IDE locus is significantly associated with a better residual beta-function with an allele-dose effect the first 12 month after diagnosis. This longitudinal study shows that genetic variants related to T2D might have an impact on disease progression in new onset T1D patients even if these same variants are found not to be predisposing to the onset of T1D. Thus, there might be some mechanistic overlap between T1D and T2D, which potentially can have therapeutic benefits for children with new onset T1D.

The PTPN22 1858T allele enhances the emergence of clinical type 1 diabetes after the initiation of beta cell autoimmunity

J. Lempainen[1], R. Hermann[1], R. Veijola[2], O. Simell[3], M. Knip[4,5], J. Ilonen[1,6];
[1]Immunogenetics Laboratory, University of Turku, [2]Department of Pediatrics, University of Oulu, [3]Department of Pediatrics, University of Turku, [4]Department of Pediatrics, Tampere University Hospital, [5]Hospital for Children and Adolescents, University of Helsinki, [6]Department of Clinical Microbiology, University of Kuopio, Finland.

Background and aims: Data on genetic factors enhancing beta-cell destruction and emergence of type 1 diabetes (T1D) after the initiation of autoimmunity is limited. We set out to analyze the role of two polymorphisms associated with T1D, PTPN22 1858C/T and insulin gene (INS) -23HphI A/T in progression to T1D after the appearance of beta-cell autoimmunity.
Materials and methods: The study population comprised 285 children from the Finnish DIPP cohort with HLA-confirmed T1D risk. All subjects had developed positivity for at least one of the T1D-associated biochemically defined autoantibodies and 136 subjects presented with T1D. Two hundred-eight subjects developed at least two biochemically defined autoantibodies, and among these 124 presented with T1D.
Results: After the appearance of the first biochemically defined beta-cell autoantibody the PTPN22 1858T allele was strongly associated with progression to T1D. Fifty-eight (60%) subjects with the TT or CT genotype presented with T1D compared to 71 (40%) subjects with the CC genotype (P<0.001, HR 2.044, 95% CI 1.425-2.931, Cox regression analysis, multivariate test for the effect of PTPN22, INS and HLA DR3/DR4 genotypes). The effect remained significant also when analyzed after the appearance of the second biochemically defined autoantibody (P=0.001). INS -23HphI AA genotype was similarly associated with progression to clinical disease after the appearance of the first autoantibody (P=0.03), but the association disappeared when analyzed after the emergence of the second autoantibody (P=0.14).
Conclusion: The PTPN22 1858T allele is strongly associated with beta-cell destruction and progression to clinical disease after the initiation of beta-cell autoimmunity. The effect of the INS genotype predisposing to beta-cell autoimmunity remained weaker and disappeared after autoantibody spreading.

Mutation in SIRT1 in familial type 1 diabetes

M. Böni-Schnetzler[1], A. Biason-Lauber[2], B.P. Hubbard[3], K. Bouzakri[4], M. Meyer-Böni[2], D. Meier[1], F. Pociot[5], G. Leibowitz[6], B. Glaser[6], H. Zulewski[7], C. Westphal[8], D.A. Sinclair[3], M.Y. Donath[1];
[1]University Hospital of Zürich, [2]University Children's Hospital, Zürich, Switzerland, [3]Harvard Medical School, Boston, USA, [4]University of Geneva, Switzerland, [5]Hagedorn Research Institute and Steno Diabetes Center, Gentofte, Denmark, [6]Hadassah Hebrew University Medical Center, Jerusalem, Israel, [7]University Hospital of Basel, Switzerland, [8]Sirtris, Boston, USA.

Background and aims: Type 1 diabetes was diagnosed in a 26-year-old Ashkenazi Jewish male on the basis of hyperglycaemia, a lean body mass index of 21.5 Kg/m^2 and β-cell auto-antibodies. The patients' sister, father, and a paternal cousin were also diagnosed with type 1 diabetes at the ages of 7, 12, and 15 years, respectively. The aims were to further characterise the patient, to identify the mutation and its pattern of inheritance and to characterise the molecular phenotype of the mutated protein.
Materials and methods: To characterise the index patient an OGTT, a euglycemic-hyperinsulinemic clamp and a muscle biopsy were performed. The mutation was identified with a candidate gene approach and exonic sequencing and introduced by site directed mutagenesis into a retroviral vector (MSCV) containing the wild type gene. Mutated and wt protein were stably expressed in 293T cells and insulin producing MIN6 cells.
Results: The index patient presented with signs of beta-cell autoimmunity (auto-antibodies to glutamic acid decarboxylase 1150 U/L and islet-cell autoantibody-2 3.0 U/L), insulin dependence and impaired beta-cell function. Further, there was an unexpected insulin resistance as revealed by a euglycemic-hyperinsulinemic clamp study (M value 34.1 10^{-3} mM / min / Kg BW) and a muscle biopsy. The affected family members lacked measurable C-peptide and were also islet auto-antibody positive. The pattern of inheritance was indicative of an autosomal dominant mutation. Analysis of SIRT1, a protein deacetylase implicated in ageing, beta-cell function and insulin resistance, revealed the presence of a T to C exchange in exon 1 of a single allele, corresponding to a Leucine-Proline mutation at residue 107 in the protein. A common polymorphism of the T to C substitution, mutations in the MODY genes and HLA associations were ruled out. Analysis of the structure of the SIRT1 protein revealed that L107P lies outside of the conserved Sirtuin enzymatic core, in a densely-charged region of the protein involved in protein-protein interactions. Isolated SIRT1-L107P protein showed only a slight decrease in deacetylase activity relative to the wild-type protein, and there were no changes in protein stability and the subcellular localization of SIRT1. Stable overexpression of L107P sirt1 protein in the beta-cell line MIN6 did not change insulin mRNA expression and insulin secretion relative to an equal expression of the wild-type protein. NF-kappaB is a known deacetylation target of SIRT1 and SIRT1 L107P MIN6 cells displayed elevated expression of NF-kappaB regulated genes iNOS, chemokine KC and cytokine TNF-alpha together with overproduction of nitric oxide.
Conclusion: Here we describe the first human mutation in the SIRT1 gene in a family with clusters of type1 diabetes. The study implicates that SIRT1 plays a role in auto-immunity and glucose homeostasis in humans and it may serve as a paradigm to initiate further screening of SIRT1 mutations in families with clusters of type 1 diabetes.

Genetic regulation of 25(OH)D_3 and 1,25$(OH)_2D_3$ serum concentrations in type 1 diabetes patients

K. Badenhoop, H. Kahles, C. Greissl, M. Penna-Martinez, F. Shoghi, E. Ramos-Lopez;
Endocrinology, Diabetes & Metabolism, University of Frankfurt am Main, Germany.

Background and aims: Growing evidence suggests an important role for the vitamin D system in the pathogenesis of type 1 diabetes. In humans, low serum levels of 25(OH)D_3 and its active form 1, 25$(OH)_2D_3$ correlate with a higher risk for this disease. In order to become biologically active, vitamin D_3 needs to be hydroxylated first into 25(OH)D_3 in the liver by the enzyme CYP2R1. After this hydroxylation, 25(OH)D_3 binds to the vitamin D binding protein (DBP) and circulates. In the kidney 25(OH)D_3 is hydroxylated to 1,25$(OH)_2D_3$ by CYP27B1. Then 1,25$(OH)_2D_3$ binds to the vitamin D receptor (VDR) to exert its immunmodulator effects via vitamin D response elements (VDRRE). Catabolism of both the 25(OH)D_3 and 1,25$(OH)_2D_3$ occur via the 24-hydoxylase (CYP24). Therefore we investigated whether genetic variation in vitamin D synthesis, metabolism, transport and catabolism influence 25(OH)D_3 and 1,25$(OH)_2D_3$ serum levels in type 1 diabetes patients.
Material and methods: 223 type 1 diabetes patients were genotyped for polymorphisms (n= 13) within the VDR- (rs7975232, rs731236, rs1544410, rs10735810), the CYP2R1- (rs10741657, rs12794714), the DBP-(rs4588, rs7041), the CYP27B1- (rs10877012) and the CYP24- (rs229641, rs2248137, rs2585426, rs927650) genes by using restriction fragment length polymorphism or real time PCR. The 25(OH)D_3 and 1,25$(OH)_2D_3$ serum levels were measured by radioimmunoassay (DIASORIN). Concentrations of 25$(OH)_2D_3$ < 20 ng/ml were defined as vitamin D insufficiency, while a range of 19.9-67 pmol/ml of 1,25$(OH)_2D_3$ was considered normal. The non-parametric Wilcoxon-Mann-Whitney -test was used for the statistic analysis. A p value < 0.05 was considered as significant.
Results: Deficiency of 25(OH)D_3 or 1,25$(OH)_2D_3$ was found in 54% and 9.4% respectively. Of the 13 analyzed polymorphisms the rs10877012, rs10741657 and the rs7041 within the CYP27B1, CYP2R1 and the DBP genes, respectively, had a statistically significant influence on the serum concentrations of 25(OH)D_3 or 1,25$(OH)_2D_3$. Thus patients carrying the allele C of the CYP27B1, which has been reported to be a risk factor to develop type 1 diabetes, had lower 1,25$(OH)_2D_3$ serum levels (34 pmol/L) than those patients carrying the alleles A (42 pmol/L) or AC (38 pmol/L; p<0.05). Also patients carrying the allele T of the rs7041 within the DBP gene showed lower levels of 25(OH)D_3 (p<0.02), whereas patients with the genotype A of the rs10741657 within the CYP2R1 had higher levels of 25(OH)D_3 in comparison to those patients without these genotypes (p<0.03).
Conclusion: This study demonstrates that vitamin D serum levels, both 25(OH)D_3 and 1,25$(OH)_2D_3$, are regulated by genetic variations at least within the genes coding for CYP27B1, CYP2R1 and DBP altering 25(OH)D_3 and 1,25$(OH)_2D_3$ concentrations. Therefore these genetic variants are functionally relevant and may thereby predispose to impaired function of the immune system in type 1 diabetes through systemic and/or tissue specific differences in vitamin D action.

PS 3 Genome-wide association studies and their follow-up

281

Meta-analysis of sex-specific genome-wide association studies of type 2 diabetes

A.P. Morris[1], S. Cauchi[2], M. Ganser[3], H. Grallert[4], G. Thorleifsson[5], B.F. Voight[6], The DIAGRAM Consortium;
[1]Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, [2]Institute of Biology, Pasteur Institute, Lille, France, [3]Department of Biostatistics, University of Michigan, Ann Arbor, USA, [4]Institute of Epidemiology, Helmholtz Zentrum Muenchen, Neuherberg, Germany, [5]deCODE Genetics, Reykjavik, Iceland, [6]The Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, USA.

Background and aims: Genome-wide association studies (GWAS) of type 2 diabetes (T2D) have identified more than thirty confirmed loci contributing effects to the disease. However, despite this success, much of the genetic component of T2D susceptibility remains unexplained. One potential source of genetic variation contributing to this "missing heritability" is that with effects that differ in magnitude and/or direction in males and females. Sex-specific effects have been observed in a variety of traits, including lipid levels and schizophrenia, but may not be readily identified through traditional analysis of GWAS of males and females, combined, because of a lack of statistical power. We have therefore undertaken the first large-scale meta-analysis of sex-specific T2D GWAS to address the following aims: (i) assess the heterogeneity of effects between the sexes at confirmed disease loci; and (ii) identify novel male- and female-specific associations with the disease for follow-up.
Materials and methods: We performed GWAS of T2D in six cohorts of northern European ancestry (total effective sample size of 9332 males and 7744 females). Genotype data were imputed in each cohort for up to 2.5 million SNPs, genome-wide, including the X chromosome. SNPs were subsequently tested, in males and females separately, for association with disease under an allelic-dose model, adjusting for cohort specific covariates. For each sex, allelic odds ratios (OR) were then combined across cohorts through fixed-effects inverse-variance weighted meta-analysis. Heterogeneity of combined allelic OR between males and females was assessed by means of Cochran's *Q*-statistic.
Results: Among confirmed T2D loci, allelic effects between males and females were generally homogeneous. However, there was nominal evidence of heterogeneity at two loci, both demonstrating stronger effects on T2D in males: *BCL11A* (p = 0.023, male OR = 1.16 [1.10-1.24], female OR = 1.05 [0.99-1.12]); and *KCNQ1* (p = 0.036, male OR = 1.15 [1.08-1.22], female OR = 1.04 [0.98-1.12]). The strongest novel signals of association with T2D in sex-specific meta-analyses were observed in males, with SNPs at two loci achieving genome-wide significance ($p<5\times10^{-8}$): proximal to *SLC35D3* ($p=1.7\times10^{-8}$, OR = 1.19 [1.12-1.26]); and proximal to *DGKB* ($p=2.5\times10^{-8}$, OR = 1.26 [1.16-1.37]). The male-specific signal at *DGKB* is independent of the overall T2D association previously reported at this locus (r^2=0.023). Novel signals with suggestive evidence of association ($p<10^{-5}$) were observed at 7 additional loci in males, and at 14 loci in females, both sets incorporating genes with plausible biological candidacy for T2D.
Conclusion: Sex-specific GWAS of T2D did not highlight strong evidence of heterogeneity of allelic effects between males and females at already confirmed loci. SNPs from 23 regions with at least suggestive evidence of association, identified using male- and female-specific meta-analyses, are currently being followed up in additional cohorts through in silico replication and de novo genotyping.

282

Age-dependent genetic effects on post-load glucose during 18 years of follow-up of the Whitehall II Cohort

C. Langenberg[1], A.C. Jensen[2], A. Barker[1], E.J. Brunner[3], A.D. Hingorani[3], M. Kumari[3], M. Kivimäki[3], N.J. Wareham[1], A.G. Tabák[3], D.R. Witte[2];
[1]MRC Epidemiology Unit, Cambridge, United Kingdom, [2]Steno Diabetes Center, Gentofte, Denmark, [3]Department of Epidemiology & Public Health, London, United Kingdom.

Background and aims: Cross-sectional, genome-wide association studies have recently identified common, single nucleotide polymorphisms (SNPs)

associated with fasting and/or 2-hour post-load glucose levels in non-diabetic individuals. It is unknown whether effects of these variants are constant over time or change with advancing age, as most genetic studies rely on glucose measurements at a single time point.
Material and methods: A total of 4,519 non-diabetic British civil servants (aged 40-78 years) participating in the Whitehall II study and attending up to four 5-yearly clinic visits including repeated oral glucose tolerance tests were studied. A weighted genetic score of glucose raising alleles was calculated separately for fasting and 2-hour glucose levels, including 16 and 5 SNPs respectively (mean score (SD) 17.0 (3.0) for fasting and 4.0 (1.4) for 2-hour glucose). Multilevel models accounting for the dependence of measurements within individuals and adjusted for sex and BMI were used to study the main effects of each genotype score on fasting and 2-hour glucose levels and their interactions with age.
Results: Over a mean follow-up of 10 years (range 0-18 years), 2-hour but not fasting glucose levels showed a significant increase with age (0.048 (95%CI: 0.037-0.058) mmol/l per year in participants without any risk alleles). The fasting glucose score significantly predicted glucose levels at 55 years (0.030 (95%CI: 0.026-0.034) mmol/l difference per genetic score point), an effect that remained constant over time (figure 1, left). At age 55 years, 2-hour glucose levels differed by 0.070 (95%CI: 0.044-0.096) mmol/l per genetic score point; notably, this effect became stronger with increasing age (0.004 (95%CI: 0.001-0.006) mmol/l per genetic score point per year), resulting in diverging age trajectories by genetic score (figure 1, right).
Conclusion: Genetic effects on 2-hour glucose appear to depend on age, such that the difference in 2-hour glucose levels per additional risk allele increases with advancing age. Our findings suggest that the effects of age or related environmental factors need to be taken into account when studying genetic influences on 2-hour glucose levels.

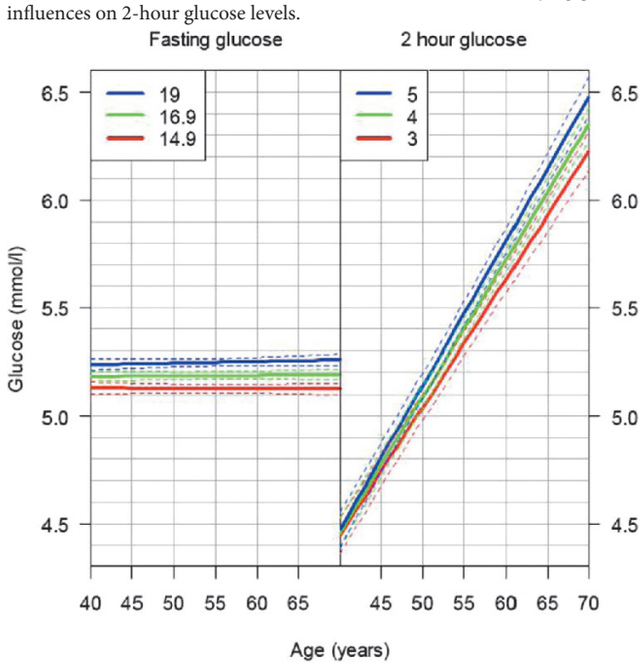

Figure 1: Estimated glucose levels and confidence intervals in males with BMI of 23 kg/m², for quartiles of the gene score distribution. Left: Fasting glucose. Right: 2-hour glucose. Colours indicate quartile values of the gene score.

Genetic predisposition to long-term deterioration in glucose homeostasis: 10-yr follow-up of the GLACIER Study

D. Shungin[1,2], F. Renström[1,3], I. Johansson[2], MAGIC investigators, J.C. Florez[4], G. Hallmans[5], F.B. Hu[4], P.W. Franks[1];
[1]GECRG, Department of Public Health & Clinical Medicine, Umeå, [2]Department of Odontology, Umeå University, Sweden, [3]Department of Nutrition, Harvard School of Public Health, Boston, [4]Massachusetts General Hospital and Harvard Medical School, Boston, USA, [5]Department of Public Health & Clinical Medicine, Section for Nutritional Research, Umeå, Sweden.

Background: Major advances have recently been made in discovering genetic loci for hyperglycemia. These findings emerged primarily through genome-wide scans of cross-sectional data. Little is known of how these loci affect changes in glycaemia over time.
Methods: Sixteen recently discovered fasting glucose-raising loci were genotyped in middle-aged non-diabetic participants in the GLACIER Study, a population-based prospective cohort from Northern Sweden. Genotypes were tested for association with baseline fasting and 2-hr glucose concentrations (N=16,048), and with change in glucose concentrations and the development of impaired fasting glucose (IFG) over 10-yrs follow-up (N=4,109).
Results: Cross-sectional directionally consistent replication with fasting glucose levels was achieved for 12/16 variants. After adjusting for fasting glucose levels, the fasting glucose risk alleles for 4 loci were positively and 3 loci were negatively associated with 2-hr glucose concentrations. In a genetic risk score (GRS) derived by adding unweighted risk alleles, those in the 80th GRS percentile had fasting glucose levels 0.17 mmol/l higher than those in the 20th GRS percentile (P=5.3x10^{-35}). In prospective analyses (Table 1), fasting glucose-raising alleles at 5 loci were nominally associated with worsening fasting glycaemia, 3 also predicted the development of IFG. After adjustment for baseline and follow-up fasting glucose, 2 variants were nominally associated with change in 2-hr glucose levels, (*ADCY5* rs11708067, *MTNRB1* rs10830963). Surprisingly the *MTNRB1* variant, which was predictive of worsening fasting glycaemia, was protective of deterioration in 2-hr glycaemia. The GRS (80th vs. 20th percentiles) was associated with 0.13 mmol/l (P=4.3x10^{-5}) greater elevations in fasting glucose and 1.34-fold (95% CI: 1.07-1.70) greater risk of developing IFG during 10-yrs follow-up. Adjusting the fasting glucose models for 2-hr glucose, or vice versa, or weighting the GRS by previously published effect estimates did not materially affect these results.
Conclusion: Multiple genetic loci predict deteriorations in fasting glucose concentrations during 10-yrs follow-up of a Northern Swedish cohort. Studies testing prospective relationships with the development of diabetes complications will be required to determine the clinical value of these genetic prediction models.

Table 1 The ability of each single nucleotide polymorphism (SNP), singularly and in combination, to predict changes in fasting and 2-hr glucose levels and development of impaired fasting glucose (IFG) over a 10-yr follow-up period (n=4,109).

SNPs are ranked by P-value of the per-allele effect (beta) on fasting glucose. Models are adjusted for age, sex and follow-up time. In the model where fasting glucose or 2-hr glucose is the outcome, models are also adjusted for baseline fasting or 2-hr glucose levels, respectively. All genotypes are located on the plus strand and are coded according to HAPMAP CEU (Phase II+III), release 27, NCBI build 36). SE = standard error; OR = odds ratio; CI = confience limit, GRS = genetic risk score

Glycaemia determines the effect of type 2 diabetes risk genes on insulin secretion

M. Heni, C. Ketterer, C. Thamer, S.A. Schäfer, M. Guthoff, K. Kirchhoff, F. Machicao, H. Staiger, A. Fritsche, H.-U. Häring;
Department of Internal Medicine IV, Tübingen, Germany.

Background and aims: Several polymorphisms in genes associated with diabetes risk reduce glucose- and/or incretin-induced insulin secretion. In this study, we investigated whether there are interactions between glycemia and such diabetes-risk polymorphisms. We hypothesized that diabetes risk genes specifically associated with impaired incretin-induced insulin secretion would show a glycemia dependent effect on insulin secretion.
Materials and methods: Insulin secretion was assessed by insulinogenic index and AUCC-pep/AUCGlc in 1576 subjects with various glucose tolerance statuses using an oral glucose tolerance test. Participants were genotyped for SNPs which were previously shown to be associated with type 2 diabetes and impaired insulin secretion and specifically impaired incretin-induced insulin secretion (rs7903146 [TCF7L2], rs10010131 [WFS1]). Furthermore, the impact of the interaction between genetic variation in TCF7L2 and glycemia on changes in insulin secretion was tested in 315 individuals taking part in a lifestyle intervention study for 9 months.
Results: For two SNPs (TCF7L2, WFS1) we found a significant interaction with glucose control on insulin secretion (all p less of equal 0.0018 for glucose x genotype). When plotting insulin secretion against glucose at 120 minutes during the OGTT, the compromising effect of the risk alleles on insulin secretion is most apparent under high glucose conditions for both SNPs. In the longitudinal study, rs7903146 in TCF7L2 showed a significant interaction with baseline glucose tolerance on change in insulin secretion during lifestyle intervention (p=0.0008). Increased glucose levels at baseline predicted an increase in insulin secretion in carriers of the risk alleles, whereas the change in insulin secretion during lifestyle intervention was not influenced by blood glucose levels in carriers of the non-risk alleles. None such interaction was found for the WFS1 SNP.
Conclusion: For the diabetes risk genes TCF7L2 and WFS1 which are associated with impaired incretin signaling, glycemia determines SNP effects on insulin secretion. This implicates the relevance of these SNPs in different stages of the pathogenesis towards type 2 diabetes mellitus.

285

The risk allele score for type 2 diabetes mellitus were associated with age of diagnosis and basal insulin secretion in Japanese population

M. Iwata[1], Y. Kamura[1], C. Kobashi[1], M. Ishiki[1], I. Usui[1], K. Yamazaki[1], M. Urakaze[1], K. Tobe[1], A. Takano[2], R. Temaru[3], H. Kato[4], S. Murakami[2], N. Akagawa[5], Y. Fukushima[5], K. Higuchi[6];

Background and aims: T2DM is a multifactorial disease whose onset depends not only on the genetic predisposition, but also environmental factors, and it remains unclear to what extent genetic predisposition affects the clinical presentation. Large-scale studies in Europe have reported that the odds ratio of each polymorphism for the onset of diabetes is low, ranging from 1.1 to 1.5. Consequently, it is considered that the onset of diabetes mellitus may be related to the accumulation of several polymorphisms. We counted the number of risk alleles of the SNPs in Japanese participants and defined the total number of risk alleles as a risk allele score. In this study, the effect of the risk allele score on the clinical presentation of T2DM was investigated.
Materials and methods: The subjects were 720 T2DM outpatients of our hospital and associated hospitals, and 760 non-diabetic controls. Ten SNPs out of 10 candidate T2DM-susceptibility genes, namely, HHEX , CDKAL1 ,CDKN2A/B, SLC30A8 KCNJ11 , IGF2BP2, PPARG, TCF7L2, FTO and KCNQ1 were genotyped by TaqMan PCR assay. Clinical information, including the current BMI, age at diagnosis of diabetes, age at the maximum body weight, family history, disease duration, FPG, HbA1c, F-CPR(= fasting serum CPR), CPI (=F-CPR*100/FPG), UCPR (=urinary C-peptide)/Cr and treatment was collected.
Results: Of the 10 genes, a significant difference between the T2DM group and control group was found for 5 genes, namely, CDKAL1, CDKN2A/B, SLC30A8, IGF2BP2 and KCNQ1. Based upon the frequency distribution of the risk alleles of the 5 SNPs, which were significantly associated with type 2 diabetes, we classified the participants into low-(a total of four or fewer risk alleles), intermediate-(a total of five or six risk alleles) and high-(a total of seven or more risk alleles)risk genetic groups. In the comparison of the clinical presentation between the low-risk group and high-risk group, although the maximum BMI of the latter group (27.0) was significantly lower than that of the former group (28.3) (p<0.01), the age at diagnosis of diabetes in the latter group (49.4 years) was significantly younger than that of the former group (52.1 years) (p<0.05). However, there was no significant correlation between the total number of risk alleles (0-2) for each gene and the age at diagnosis of diabetes mellitus. Regarding the indices of the basal linsulin secretary capacity, the F-CPR, CPI and UCPR/Cr were all significantly lower in the high-risk group than in the low-risk group, after adjustments for age, sex, FPG, BMI, and duration of diabetes (p<0.01). The ratio of insulin therapy in the high-risk group (37%) was greater than that in the low-risk group (25%) (p<0.05).
Conclusion: It was demonstrated that while the risk alleles for each individual polymorphism had little effect on the onset of diabetes, the high risk allele score of 5 SNPs, which were associated with significantly associated with type 2 diabetes in this study, was related with earlier age at onset of diabetes, decreased insulin secretion and increment of the ratio of insulin therapy.

Replication of European GWAS-derived type 2 diabetes susceptibility SNPs in Pakistani populations

S. Rees[1], S. Bellary[2], M.Z.I. Hydrie[3], J.P. O'Hare[4], S. Kumar[4], A.S. Shera[5], A. Basit[3], A.H. Barnett[2,1], M.A. Kelly[1];
[1]College of Medical and Dental Sciences, University of Birmingham, [2]Heart of England NHS Foundation Trust, Birmingham, United Kingdom, [3]Baqai Institute of Diabetology and Endocrinology, Karachi, Pakistan, [4]Warwick Medical School, University of Warwick, Coventry, United Kingdom, [5]Diabetic Association of Pakistan, Karachi, Pakistan.

Background and aims: Type 2 diabetes (T2D) is a major public health issue in the Indian subcontinent (India, Pakistan and Bangladesh), where it is predicted that the disease will affect approximately 76 million adults by 2025. A high prevalence of the disease is also observed in populations of South Asian ancestry living in other areas of the world. Although lifestyle factors, such as diet and exercise, undoubtedly contribute to the development of T2D, these factors cannot fully explain the high prevalence of the disease in South Asian populations. This excess risk has been partly attributed to the genetic background of the population. Recently the advent of genome-wide association studies (GWAS) has led to the discovery of a number of novel SNPs (single nucleotide polymorphisms) that confer risk of T2D development. The majority of these large scale studies, however, have investigated cohorts of white European origin, and South Asian populations have been considerably understudied. In this study we investigated 16 SNPs that have been robustly associated with T2D in Europeans to determine whether they have a similar effect on disease risk in two Pakistani populations of Punjabi ancestry, one UK-resident and one indigenous to Pakistan.
Materials and methods: We genotyped 2992 subjects (1609 with T2D and 1383 normoglycaemic controls) for 16 SNPs using either TaqMan (AppliedBiosystems, Warrington, UK) or KASPar (KBiosciences, Hoddesdon, UK) methods. One SNP was chosen from each of the following loci: *TCF7L2, CDKN2A/2B, CDKAL1, HHEX/IDE, IGF2BP2, CDC123/CAMK1D, SLC30A8, PPARG, KCNJ11, WFS1, TCF2, ADAMTS9, THADA, NOTCH2, TSPAN8/LGR5, JAZF1*. Logistic regression was used to investigate the association between each SNP and T2D, using an additive model and including sex, age and population as covariates. An allelic risk score variable was constructed using those SNPs that showed some evidence (p<0.1) for association with T2D, by combining the total number of risk alleles for each subject.
Results: Significant associations with T2D were observed for *TCF7L2* (OR=1.25 [1.12, 1.40] *p*=0.00008), *CDKN2A/2B* (OR=0.79 [0.67, 0.93] *p*=0.005), *HHEX/IDE* (OR=1.14 [1.03, 1.26] *p*=0.013), *IGF2BP2* (OR=1.18 [1.06, 1.31] *p*=0.002) and *TCF2* (OR=0.90 [0.80, 1.00] *p*=0.041). Trends towards association with T2D were also observed for *SLC30A8* (OR=0.89 [0.79, 1.01] *p*=0.064) and *PPARG* (OR=0.88 [0.75, 1.02] *p*=0.089). These variants appear to have an additive effect on T2D risk, the allelic risk score showing that each risk allele contributes a 1.15-fold increase in disease risk (OR=1.15 [1.10, 1.21] *p*=2.04 x 10-9).
Conclusion: We have demonstrated that a number of genetic variants that predispose to T2D in European populations have a similar effect in populations of Pakistani origin. Furthermore, to our knowledge this is the first time that a disease association with variants in *CDKN2A/2B*, *HHEX/IDE* and *TCF2* has been demonstrated in any South Asian population.

Evaluation of the phenotypic effects of common FTO and MC4R genetic polymorphisms in a general population from South India

S.K. Vasan[1], P. Samuel[2], B. Antonisamy[2], N. Thomas[3], M.J. Neville[4], F. Karpe[4], H.F. Gu[1], K. Brismar[1];
[1]Molecular Medicine & Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Biostatistics, Christian Medical College, Vellore, India, [3]Endocrinology, Diabetes & Metabolism, Christian Medical College, Vellore, India, [4]Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM), University of Oxford, United Kingdom.

Background and aims: Obesity is a multi-factorial trait that results from a complex interplay between genes and environment. Genome wide association (GWA) studies have shown that common variants in the FTO (Fat mass and Obesity associated) and MC4R (Melanocortin 4 receptor) genes are associated with increased risk of Obesity and type 2 diabetes in Caucasians. These associations, however, were not consistent and the effect was independent of body mass index (BMI) in the subjects with type 2 diabetes among Asians. In the present study, we aimed to evaluate the phenotypic effects of the common FTO and MC4R genetic polymorphisms in a young adult population from South India.
Materials and methods: We examined the common variants of the FTO (rs9939609) and MC4R (rs17782313) genes in two independent cohorts (n=3241) stratified based on the area of residence to rural (n=1221) semiurban (n=1023) and urban (n=997)from South India. Anthropometric measurements of adiposity including BMI, waist circumference (WC), waist-hip ratio (WHR), body fat % and skin fold thickness were performed. Serum glucose, lipids were measured in non fasting venous blood samples. The data were summarized by comparing means across groups by ANOVA and Kruskall Wallis tests respectively for normal distributed and skewed variables. Comparative analyses of genotype frequencies between study groups were performed using chi-square test. Phenotypic effects in each genotypes were deduced based on dominant/recessive models using multivariate logistic regression analyses.
Results: The rural group comprised of lean phenotypes with low mean BMI (19.8 ± 3.4) and WHR (0.83 ±0.07) while the urban population had a significantly higher mean BMI (21.8 ± 3.9, p<0.001), higher WC (77.1 ± 10.9, p<0.001) and higher fasting blood glucose (5.6 ± 1.0) compared to the rural and semi-urban groups. Despite a lean phenotype, the homozygous AA genotype of the FTO gene, was significantly associated with higher body fat % (23.2 ± 9.6, p=0.03), Skin fold measurements at triceps (median 9.55 interquartile range 6.53-14, p=0.004), biceps (median 4.53, range 3.13-7.22, p=0.03), subscapular (14.73, range 10.35-25.88, p=0.01) and abdomen (median 16.13, range 8.63-30.55, p=0.002) in the rural group. Significant association with anthropometric measurements was not seen among the urban and the semi urban group though they had a significantly higher BMI and subcutaneous fat. A similar trend was also observed amongst the rural population in the homozygous CC genotype of MC4R with modest significance.
Conclusion: Data from the present study suggests that the common variants of the FTO and MC4R genes have significant genetic influence on subcutaneous fat and body fat percentage, but not BMI in the South Indian population.

Common variant of MTNR1B is associated with difficulties maintaining sleep but fails to influence the association between sleep disturbances and type 2 diabetes: the HUNT study

L. Olsson[1], E. Pettersen[2], A. Ahlbom[1], S. Carlsson[1], K. Midthjell[3], V. Grill[2,4];
[1]Department of Epidemiology, Karolinska Institutet, Stockholm, Sweden, [2]Department of Cancer Research and Molecular Medicine, The Norwegian University of Science and Technology, Trondheim, [3]Department of Community Medicine and General Practice, HUNT Research Centre, The Norwegian University of Science and Technology, Levanger, [4]Department of Endocrinology, St. Olav University Hospital, Trondheim, Norway.

Background and aims: Recent studies have demonstrated that genetic variation in the melatonin receptor 1B (MTNR1B) is associated with type 2 diabetes. Melatonin contributes to the regulation of sleep, and sleep problems are a documented risk factor for type 2 diabetes. Whether the MTNR1B gene variant, which confers risk of diabetes, induces sleep problems is not known, nor whether a putative effect on sleep impacts on the link between sleep problems and type 2 diabetes. We tested 1) whether the risk variant SNP rs10830963 in the MTNR1B gene is associated with self reported sleep problems, and 2) whether presence of the risk variant influences the association between sleep disturbances and type 2 diabetes.
Materials and methods: We used information from a case-control study nested within the population-based Nord-Trøndelag Health Study, including 1,074 cases of type 2 diabetes and 1,447 controls (matched by age and sex). Information on different aspects of sleep disturbances was obtained by questionnaire. Genotyping was performed using the Tacman discrimination assay (Applied biosystems). Odds ratios (OR) and 95% confidence intervals (CI), adjusted for age, sex and BMI, were calculated using logistic regression models.
Results: Reported difficulties maintaining sleep were more frequent in subjects with the G allele of the rs10830963 (OR 1.49, 95% CI 1.04-2.14). In confirmation of previous studies, this allele also conferred increased risk of type 2 diabetes (OR 1.19, 95% CI 1.01-1.41). However, the previously documented association between sleep problems and type 2 diabetes was not influenced by the MTNR1B G allele. Hence, the OR for the association between sleep disturbances and type 2 diabetes was 1.46 (95% CI 1.01-2.10) for subjects with the G allele of rs10830963, and 1.53 (95% CI 1.08-2.16) for subjects without the G allele.
Conclusion: The common variant rs10830963 in the MTNR1B gene is associated with difficulties maintaining sleep and also with type 2 diabetes. However, presence of the risk allele does not influence the association between sleep disturbances and type 2 diabetes.

Expression of ARL15, a type 2 diabetes risk variant, is increased in cultured human skeletal muscle cells from insulin-resistant type 2 diabetes patients

A.E. Brown[1], C.J. Williams[1], N. Rocha[2], J.B. Richards[3,4], R. Semple[2], M. Walker[1];
[1]Institute of Cellular Medicine, Newcastle University, [2]University of Cambridge Metabolic Research Laboratories, Institute of Metabolic Science, University of Cambridge, United Kingdom, [3]Departments of Medicine, Human Genetics and Epidemiology and Biostatistics, McGill University, Montreal, Canada, [4]Twin Research and Genetic Epidemiology, King's College London, United Kingdom.

Background and aims: A recent genome wide association (GWAS) meta-analysis identified a new variant in the *ARL15* gene associated with decreased circulating adiponectin levels, and increased risk of coronary heart disease and type 2 diabetes. *ARL15* (ADP-ribosylation factor-like 15) encodes a GTP-binding protein of unknown function that is highly expressed in skeletal muscle. The aim of this study was to investigate *ARL15* expression in cultured human skeletal muscle cells, and to determine (1) whether expression changed with differentiation from myoblasts to myotubes, and (2) whether expression was altered in cultured muscle cells from insulin resistant type 2 diabetic patients.
Materials and methods: Cultured skeletal muscle cells derived from type 2 diabetic patients with a family history of diabetes and clinical evidence of insulin resistance and healthy non-diabetic control subjects with no family history of diabetes were studied. We have previously shown that defects of insulin action are retained in the cultured myotubes from the diabetic patients. *ARL15* expression was measured in cultured myoblasts and day 7 differentiated myotubes. Quantitative real-time PCR (QPCR) was used to measure gene expression relative to GAPDH as the reference gene, while protein expression was determined by Western blotting. Statistical analyses were performed using the Wilcoxon signed rank and Mann Whitney U tests.
Results: In cultures from healthy control subjects, *ARL15* was expressed in both myoblasts and myotubes and increased with differentiation. After normalisation to GAPDH, expression increased from 0.24±0.06 (mean±SEM) units in myoblasts to 0.68±0.25 in myotubes (n=9; p=0.03). Western blotting confirmed ARL15 protein expression in both myoblasts and myotubes, and was 1.6-fold higher following differentiation to myotubes (n=3; p=0.04). *ARL15* expression was compared between cultured muscle cells obtained from 6 insulin-resistant type 2 diabetic patients and 6 age- and BMI-matched controls. *ARL15* expression tended to be higher in diabetic vs control myoblasts (0.44±0.24 vs 0.12±0.04 units; p=0.06). *ARL15* expression increased with differentiation in both groups, and was significantly higher in the diabetic vs control myotube cultures (0.94±0.27 vs 0.25±0.05 units, p=0.004).

Conclusion: These data show that *ARL15* and the encoded protein are well expressed in cultured human skeletal muscle cells, and expression increases with differentiation. *ARL15* expression was increased in differentiated myotubes from insulin resistant type 2 diabetic patients. Further work is needed to explore whether the increased *ARL15* expression in the diabetic myotubes is directly related to the previously observed impairment of insulin action in these muscle cell cultures.

Whole genome sequencing identifies naturally-occurring polymorphisms in a polygenic model of spontaneous type 2 diabetes
P.J. Kaisaki, M. Ria, A. Rimmer, K. Argoud, A. Authier, R. Yahia, G. Lunter, D. Gauguier;
Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

Background and aims: The GK rat is a well-established inbred model of type 2 diabetes (T2D), spontaneously exhibiting the main features of T2D, as the consequence of naturally-occurring diabetes-causative DNA variants isolated from an outbred Wistar stock By making use of massively parallel next-generation sequencing technologies, our aim was to sequence the entire genome of the GK rat at sufficient coverage for accurate identification of nucleotide and possibly structural variants. More particularly we will examine GK genomic regions linked to phenotypes related to T2D and other metabolic traits as well as genes found to be differentially expressed between GK and control strains through genome-wide gene expression (eQTL) studies.
Materials and methods: Genomic DNA is extracted from GK rat liver using Qiagen DNeasy blood and tissue kit. The DNA is fragmented, and adaptors are ligated to the fragments to make a library for 51-bp paired-end sequencing on an Illumina Solexa Genome Analyzer II next-generation sequencer. Solexa software is used for base calling (Bustard) and initial alignment (GERALD) with the ELAND algorithm. Further alignments are carried out using STAMPY, and SNP detection by an in-house algorithm at the Wellcome Trust Centre for Human Genetics.
Results: In total, 29 lanes of sequencing were run, giving a total of about 330 million 51-bp reads, and resulting in approximately 9x average coverage across the genome. Currently 80% of the sequence maps back to the BN rat RGSC 3.4 assembly. Looking specifically in a 6.32Mb region carried by a congenic rat strain bred to capture a GK diabetes QTL, we find 14,453 candidate SNPs, some in genes that have emerged from monogenic family studies and genome wide association studies in humans, including Glis3, as well as in Dmrt3, a novel candidate which is an expression QTL in GK. Gene expression and physiological QTLs are now annotated with a more complete set of SNPs and other variants.
Conclusion: We have generated whole genome sequence for the GK rat, aligned it to the BN reference sequence, and have identified sequence variants in candidate genes for T2D. Integration of whole genome polymorphism data with physiological and genome-wide gene expression quantitative trait loci in F2 crosses and congenic strains, provides a powerful novel resource for understanding the full genomic landscape of spontaneous polygenic T2D and for identifying new candidate genes and pathways contributing to T2D and the metabolic syndrome.

What can a meal test tell us about the heritability of the beta cell function?
A.M.C. Simonis-Bik[1], D.I. Boomsma[2], J.M. Dekker[3], M. Diamant[1], E.J.C. de Geus[2], L.M. 't Hart[4], R.J. Heine[1], M.H.H. Kramer[5], A.J. Maassen[1], A. Mari[6], A. Tura[6], G. Willemsen[2], E.M.W. Eekhoff[1];
[1]Diabetes Centre, VU University Medical Centre, Amsterdam, [2]Biological Psychology, VU University Amsterdam, [3]Epidemiology and Biostatistics and EMGO institute for Health and Care Research, VU University Medical Centre, Amsterdam, [4]Molecular Cell Biology and Medical Statistics, Leiden University Medical Centre, [5]Internal Medicine, VU University Medical Centre, Amsterdam, Netherlands, [6]CNR Institute of Biomedical Engineering, Padova, Italy.

Background and aims: Type 2 diabetes is a multi-factorial disease in which deterioration of the beta cell function plays a crucial part. This same-sex twin family study is the first to assess the heritability of beta cell function parameters derived from the most physiological challenge test, the mixed-meal tolerance test.
Materials and methods: We recruited 77 same-sex twin families from the Netherlands Twin Register, including 51 MZ twin pairs, 21 DZ twin pairs, 5 twins without a co-twin and 34 same-sex siblings of the twins. All 183 healthy participants (77 male) were of European origin and aged 20-49 years. After anthropometric measurements were performed, a standardized mixed-meal was given and blood was sampled repeatedly. Glucose, insulin and C-peptide levels were determined to calculate the insulin sensitivity, the insulinogenic index, insulin levels at different time periods, 4 parameters of postprandial glycaemia and 9 model derived (Mari) parameters of beta-cell function, namely beta-cell glucoses sensitivity, rate sensitivity, potentiation factor ratios and insulin secretion rate in 5 different periods. All genetic analyses were carried out in Mx, a structural equation modeling program. In the univariate analyses the heritability of each variable was estimated individually. Subsequent multivariate analyses were performed to test overlap in the genetic factors influencing beta cell function, waist circumference and insulin sensitivity.
Results: The highest heritability was found for the insulinogenic index (63%), of which one third was shared with waist and insulin sensitivity. Beta cell glucose sensitivity had a heritability of 50% with a negligible overlap with genetic factors for waist and insulin sensitivity. Insulin secretion rate was only heritable before and during the first 2 postprandial hours (range 40-45%). Genetic factors determine half of the variability of the insulin sensitivity and of the postprandial glycaemic responses during mixed-meal tolerance tests. The fasting insulin but not postprandial insulin levels showed significant heritability (38%). In 7 beta cell function parameters, of which 5 were model-derived, genetic influence did not reach significance.
Conclusion: Classical and model derived beta cell function parameters of the first two hours of a meal test show a significant heritability. These parameters provide important physiological data that can be used to follow up results of gene finding studies.

Genetic variability of G6PC2 influences beta cell function and insulin sensitivity in patients with newly diagnosed type 2 diabetes
F. Turrini[1], S. Bonetti[1], M. Trombetta[1], L. Boselli[1], E. Trabetti[2], G. Malerba[2], P.F. Pignatti[2], M. Muggeo[1], I. Pichiri[1], E. Bonora[1], R.C. Bonadonna[1];
[1]Department of Medicine, [2]Department of Life and Reproduction Sciences, University of Verona, Italy.

Background and aims: *G6PC2* (glucose-6-phosphatase catalytic subunit 2) is the catalytic subunit of glucose-6-phosphatase and it has specific expression in the beta cell. The rs560887 G allele of *G6PC2* is associated with higher levels of fasting plasma glucose (G) and increased first phase of insulin secretion during IVGTT. We evaluated the role of genetic variation at *G6PC2* in determining clinical and pathophysiological traits in patients with newly diagnosed type 2 diabetes (T2D).
Methods: 494 GAD-negative and drug-naïve patients (age 57.7±10.3 years, BMI 29.9±5.1 kg/m^2, HbA1c 7.0±1.4 %) with newly diagnosed T2D underwent standard clinical characterization. Furthermore, beta cell function (BF) and insulin sensitivity (SI) were assessed by mathematical modeling of G/C-

peptide curves during a 240' frequently sampled OGTT and by euglycemic insulin clamp, respectively. The beta-cell responses to the rate of increase of G (derivative or dynamic control: DC; median[IQ range]: 430[0.6-904] [pmol·m^{-2} BSA]/[mM·min^{-1}]) and to G concentration (proportional or static control, PC, presented as the insulin secretion rate at G concentrations of 5.5, 8.0, 11.0, 15.0 and 20.0 mM, respectively; 160±68, 222±121, 358±219, 569±378, 839±594 pmol·min^{-1}·m^{-2} BSA) are herein reported as measures of BF. SI is presented as the M value in the last 60' of the clamp (561[355-796] µmol·min^{-1}·m^{-2} BSA). We genotyped the following tag SNPs which reportedly capture ~95% of genetic variability of *G6PC2* locus: rs853770 , rs483109, rs12475700 (a), rs13387347 (b) and rs560887 (c). We report the results of variants a, b and c, because of their relevance to BF and SI.
Results: Both in our patients and in HapMap, a higher LD value (r^2= 0.54) was found between the proximal (a) and the distal (c) variant than between adjacent SNPs (a/b r^2= 0.10; b/c r^2= 0.29). Consistently with this observation, both major alleles of rs12475700 (A allele, frequency: 0.56) and rs560887 (G allele, frequency: 0.70) were associated with increased DC (A allele: +90±46, p<0.05; G allele: +95±49, p<0.03). In turn, the rs13387347 A allele (frequency: 0.43) was associated with reduced SI (-44±22, p<0.03), and increased levels of fasting C-peptide (+0.086±0.024 nmol/L, p=0.002) and insulin (+8.4±3.1 pmol/L, p<0.002). The increases in C-peptide/insulin were statistically significant also after adjustment for SI (p=0.006 and p<0.05 respectively).
Conclusion: In patients with newly diagnosed type 2 diabetes the *G6PC2* locus is associated with changes in BF and in SI of opposite sign, only partially explained with reciprocal compensation. These data could be of etiopathogenic and pathophysiological relevance and lead to clinical and therapeutic applications.

Potential role of MTNR1B locus in regulating beta cell function and glucose levels in patients with newly diagnosed type 2 diabetes
S. Bonetti[1], M. Trombetta[1], F. Turrini[1], L. Boselli[1], E. Trabetti[2], G. Malerba[2], P.F. Pignatti[2], M. Muggeo[1], E. Bonora[1], R.C. Bonadonna[1];
[1]Department of Medicine, [2]Department of Life and Reproduction Sciences, University of Verona, Italy.

Background and aims: The high affinity melatonin receptor, *MTNR1B*, is expressed in brain, retina and endocrine pancreas. In non-diabetic subjects, the *MTNR1B* variant rs10830963 is associated with increased levels of fasting glucose (G), reduced beta cell function (BF) and increased risk of developing type 2 diabetes (T2D). We investigated the role of *MTNR1B* in determining clinical and pathophysiological traits in patients with newly diagnosed T2D.
Materials and methods: 494 GAD-negative and drug-naïve patients (age 57.7±10.3 years, BMI 29.9±5.1 kg/m^2, HbA1c 7.0±1.4 %) with newly diagnosed T2D underwent standard clinical characterization. Furthermore, beta cell function (BF) and insulin sensitivity (SI) were assessed by mathematical modeling of G/C-peptide curves during a 240' frequently sampled OGTT and by euglycemic insulin clamp, respectively. The beta-cell responses to the rate of increase of G (derivative or dynamic control: DC; median[IQ range]: 430[0.6-904] [pmol · m^{-2} BSA]/[mM · min^{-1}]) and to G concentration (proportional or static control, PC, presented as the insulin secretion rate at G concentrations of 5.5, 8.0, 11.0, 15.0 and 20.0 mM, respectively; 160±68, 222±121, 358±219, 569±378, 839±594 pmol · min^{-1} · m^{-2} BSA) are herein reported as measures of BF. SI is presented as the M value in the last 60' of the clamp (561[355-796] µmol · min^{-1} · m^{-2} BSA). We genotyped the following tag SNPs which reportedly capture ~94% of genetic variability of *MTNR1B* locus:: rs7102746 e rs11523890 upstream to, rs10830963 within and rs9666752 downstream to *MTNR1B*.
Results: The LD of these SNPs was found to be consistent with HapMap (CEU popolation). The rs11523890 G allele (frequency: 0.65) was associated with reduced DC (-136±55, p=0.002). The diabetes risk allele G of rs10830963 (frequency: 0.26) was significantly associated to reduced DC in a dominant model (GG+AG:-101±45, p<0.03), and also in multivariate analysis with rs11523890 as a covariate. In the combinatory rs11523890-rs10830963 genotype, no patient was homozygous for both risk alleles (GG-GG), but a tiny group (n=6, age:49±12; BMI:29.4±4.3) was homozygous for both non risk alleleles (CC-AA) and had the best DC (1982±642; p<0.01) and the worst SI (362±101; p<0.01). Finally, the rs9666752 A allele (frequency: 0.52) was associated with increased HbA_{1c} (+0.22±0.09%, p<0.02).
Conclusion: *MTNR1B* may play a relevant role in the regulation of G levels and BF in patients with newly diagnosed T2D. These data, if confirmed. could lead to clinical and therapeutic application, including, but not limited to, identification of specific subgroups of patients for diagnostic-therapeutic purposes.

Pancreatic islets of melatonin receptor knock-out mice
C.L.F. Nagorny[1], U. Voss[2], H. Bennet[3], J.A. Stamenkovic[1], R. Sathanoori[2], M. Fex[3], N. Wierup[2], H. Mulder[1];
[1]Clinical Sciences Malmö; Molecular Metabolism, Lund University, Malmö, [2]Experimental Medical Science; Neuroendocrine Cell Biology, Lund University, Lund, [3]Clinical Sciences Malmö; Diabetes and Celiac Disease, Lund University, Malmö, Sweden.

Background and aims: Genome-wide-association studies (GWAS) have recently suggested that a receptor (MTNR1B) for the pineal hormone melatonin is involved in the pathogenesis of Type 2 Diabetes Mellitus (T2DM). Melatonin binds predominantly to its receptors MTNR1A (MT1) and MTNR1B (MT2), which are G-protein coupled receptors and are proposed to exert an inhibitory effect on insulin secretion. Here, we investigate whether a metabolic phenotype evolves in mice when melatonin receptor signalling is disrupted. Also, we examined whether a knock-out of melatonin receptors affects islet morphology and function.
Materials and methods: Knock out mice for MT1, MT2 and both receptors were kindly provided by Professor David Weaver. Every second week blood samples were taken from the Saphenous vein in awake male mice. We measured glucose and insulin concentrations in plasma. We also performed immunohistochemistry to calculate β-cell mass and area and to determine cellular location of the receptors in islets. Standard errors are given as standard deviations.
Results: Plasma glucose (8.61 ±1.43 mM) and insulin levels (1.58 ±0.98 ng/ml) did not differ between the mouse lines and did not change over time (10-22 weeks). MT2 knock-out mice were significantly heavier than WT, MT1 and MT1/2 knock-out mice (MT2: 39.7 ±1.0g; WT: 34.0 ±0.9g; MT1: 31.0 ±0.7g; MT1/2: 30.45g ±0,7). Mean β-cell mass did not vary between mouse lines, but there was a trend towards increased islet area in MT2 and MT1/2 double knock-out mice (MT2: 2.42 x 10^{-5} ±2.0 x 10^{-5} AU (Arbitrary Units); MT1/2: 2.44 x 10^{-5} ±1.7 x 10^{-5} AU; WT: 1.52 x 10^{-5} ±1.1 x 10^{-5} AU; MT1 1.39 x 10^{-5} ±1.0 x 10^{-5} AU).
Conclusion: Our data indicate differences in whole body metabolic regulation in MT2 receptor knock-out mice, since they are significantly heavier than WT, MT1 and MT1/2 knock-out mice. The trend towards increased islet area in MT2 and MT1/2 double knock-out mice suggests that MT2 and MT1/2 knock-out mice tend to have more islets than MT1 and WT mice, which could be explained by increased demands for insulin in the heavier mice.

Effects of KCNQ1 on glucose-induced insulin secretion in rat pancreatic beta cells or on glucagon-like peptide-1 secretion in cultured NCI-H716 cells
S. Maeda, S. Tsukada;
Laboratory for Endocrinology and Metabolism, RIKEN Center for Genomic Medicine, Yokohama, Japan.

Background and aims: Two genome-wide association studies conducted in Japanese populations have identified a gene encoding *KCNQ1* (potassium voltage-gated channel, KQT-like subfamily, member 1) as a strong susceptibility gene to type 2 diabetes, and the polymorphisms in the *KCNQ1* have been also shown to be associated with ß cell functions, or with secretion of glucagons-like peptide-1 (GLP-1). The aim of the present study is to know the role of the KCNQ1 in insulin secretion using isolated rat pancreatic ß cells, or in GLP-1 secretion using cultured human GLP-1 secreting cell lines (NCI-H716).
Materials and methods: We examined the expression of *KCNQ1* mRNA by real-time PCR. The rat isolated ß cells were incubated with or without choromanol 293 (specific KCNQ1 inhibitor), and insulin secretion from the cells were measured by enzyme linked immunosorbent assay (ELISA). We also measured GLP-1 secretion from the NCI-H716 cells with or without the treatment of chromanol 293 by ELISA.
Results: We found clear expressions of the *KCNQ1* as well as *KCNE2*, a ß subunit of the potassium channel, in isolated rat pancreatic islets by RT-PCR. Treatment of isolated rat ß cells with chromanol 293B (100 µM) could signifi-

cantly increase the glucose (16.7mM)-induced insulin secretion. A similar effect could be observed in isolated pancreatic ß cells under the presence of 300 µM of tolbutamide, although the difference was not statistically significant. The KCNQ1 inhibitor did not affect insulin secretion from the ß cells under low glucose conditions or under the presence of 30 mM KCl. In NCI-H716 cells, the expressions of *KCNQ1* and *KCNE1 - 5* were detected. The treatment with chromanol 293 increased bethanechol (1000 µM)-induced GLP-1 secretion, but did not affect GLP-1 secretion under a basal condition or under the presence of 10 µM ionomycine.
Conclusion: These results suggest that KCNQ1 can regulate secretion of insulin and GLP-1, and may contribute to the susceptibility to type 2 diabetes by decreasing glucose-induced insulin secretion in the pancreatic β cells or diet-induced GLP-1 secretion in the L cells.

Effects of KCNQ1 inhibitor on insulin secretion in pancreatic beta cells, or on GLP-1 secretion in NCI-H716 cells.

Polymorphisms in CACNA1D affect insulin release and channel expression and associate with type 2 diabetes
T.M. Reinbothe, V. Lyssenko, S. Lang, E. Renström;
Lund University Diabetes Centre, Lund University, Malmö, Sweden.

Background and aims: Voltage-gated Ca^{2+} channels of the L-type are essential triggers for insulin secretion in rodents but little is known about their role in human type 2-diabetes. We here set out to determine the contribution of the human L-type channel subtype $Ca_v1.3$ (encoded by CACNA1D) for inherited capacity of insulin secretion.
Materials and methods: *Gene expression in human islets:* Total RNA was isolated from pancreatic islet donors including 45 non-diabetics / 6 diabetics (24/4 males, 21/2 females, age=56±10/58±15, BMI=26±3/28±4) using the AllPrep DNA/RNA Mini Kit (Qiagen) and analyzed using Gene 1.0 ST whole transcript based assays (Affymetrix). *Genetic studies:* DNA from the Diabetic Genetics Initiative was analysed with the Affymetrix Human Mapping 500K GeneChip® in order to identify single nucleotide polymorphisms. Three candidate SNPs were tested in 766 non-diabetics (358 males, 408 females, age=49±13, BMI=25±4) from the Botnia study by genotyping using Taqman allelic discrimination assays and common variants were detected by ABI PRISM 7900. Phenotypes were assessed with oral (OGTT) or intravenous (IVGTT) glucose tolerance tests with insulin measured using a radioimmunoassay. Insulin phenotypes were corrected for age, gender and BMI.
Results: In non-diabetics, the marker rs312480 associated significantly with inappropriate fasting insulin release (IVGTT, corrected insulin response (CIR), p=0.027, additive model) and in individuals younger than 41 years significantly affected the acute insulin (AI) release (OGTT, p=0.009) as well as altered levels at time points 60 and 120 minutes (p=0.006 and 0.032 respectively). This marker also evoke our interest as it is located within the 5'UTR region of the gene, contains putative methylation sites and significantly affects expression of the gene (p=0.014) in our microarray study. The marker rs312486 was found to correlate with increases in 1- and 2-h glucose levels (OGTT, p=0.017 and 0.046 resp.). In a larger material (Botnia-PPP, 5210 individuals) this polymorphism showed significant association with type-2 diabetes status (p=0.016, OR=1.317). Interestingly, the minor allele of this marker links significantly with raised blood pressure in younger individuals (<41 years). The third SNP of interest, rs9841978, was found to relate to reductions in first phase insulin secretion (p=0.001). In addition, our microarray data suggests an association between the expression of CACNA1D and the diabetes status (p=0.025).
Conclusion: Single nucleotide polymorphisms in the $Ca_v1.3$ encoding gene CACNA1D affect mRNA expression of the channel in human pancreatic islets and associate with impaired insulin secretion as well as type-2 diabetes.

A common variant in the *PAX6* gene influences islet function in man
E. Ahlqvist[1], F. Turrini[1], S. Lang[1], T. Elgzyri[1], Y. Zhou[1], B. Isomaa[2,3], T. Tuomi[2,4], V. Lyssenko[1], L. Groop[1];
[1]Department of Clinical Sciences, Lund University, Malmö, Sweden, [2]Folkhälsan Research Centre, Helsinki, [3]Malmska Municipal Health Care Center and Hospital, Jakobstad, [4]Department of Medicine, University of Helsinki, Finland.

Background and aims: PAX6 is an important regulator of pancreas development and a key transcription factor for genes involved in glucose homeostasis, including insulin, incretins and prohormone convertase genes. Impaired glucose tolerance and insulin secretion has been reported in families with protein disrupting *PAX6* mutations and suggested to result from defective proinsulin processing due to lack of *PCSK1*. In this study we investigated the effect of a common *PAX6* variant on glucose homeostasis and insulin processing as well as expression of target genes.
Materials and methods: A candidate SNP was identified in a genome-wide association study. Association with glucose tolerance, insulin processing and secretion was assessed in four Scandinavian cohorts. Insulin secretion and expression of *PAX6* and transcriptional targets was studied in human pancreatic islets.
Results: We identified a SNP that was associated with fasting proinsulin/insulin ratio in the Diabetes Genetics Initiative (DGI) genome-wide association scan. The G allele of rs685438 was associated with lower fasting proinsulin/insulin ratio as well as with increased fasting insulin (p=0.001) and HOMA-IR (p=0.0008). Expression of *PAX6* (p=0.01) and *PCSK1* (p=0.001) was lower in pancreatic islets from human donors carrying the G-allele. The effect on fasting proinsulin/insulin ratio was also seen in the Helsinki birth cohort study (P=0.07), as was higher fasting insulin (p=0.04) and HOMA-IR (p=0.03). In the Botnia Prospective study G allele carriers had higher 2 hour insulin levels (p=0.03) and higher 2 hour glucose levels (p=0.0001). Acute arginine-stimulated insulin secretion in a cohort of 167 diabetic and non-diabetic individuals was reduced (p=0.02). Glucose stimulated insulin secretion was also significantly lower in human pancreatic islets (p=0.002). Further, G allele carriers had lower fasting plasma levels of both GIP (p=0.03) and glucagon (p=0.03).
Conclusion: A common variant in *PAX6* affects *PAX6* and *PCSK1* expression and islet function. In spite of increased insulin resistance individuals with low expression have lower proinsulin/insulin ratio rather than higher, which was previously reported for carriers of *PAX6* mutations. In contrast, they have reduced acute arginine-stimulated insulin secretion, a measure of total insulin secretion capacity, and reduced incretin levels, which is in accordance with the expected effect of PAX6 on expression of insulin and incretin mRNA.

TCF7L2-conferred apoptosis in pancreatic beta cells involves the p53 pathway
Y. Zhou[1], E. Zhang[2], E. Renström[2], L. Groop[1], O. Hansson[1,2];
[1]Clinical Sciences, Endocrinology and Diabetes, [2]Clinical Sciences, Islet Pathophysiology, Lund University, Malmö, Sweden.

Background: The SNP rs7903146 of the TCF7L2 gene increases risk for type 2 diabetes through a perturbed insulin secretion, an impaired incretin effect and impaired cell survival (increased apoptosis and/or decreased proliferation). The mechanisms by which TCF7L2 would influence beta cell apoptosis and/or proliferation are not known.
Aim: To identify the molecular mechanism/s by which TCF7L2 confers the apoptotic effect in pancreatic beta cells.
Material and methods: Chromatin immunoprecipitation on microarray (ChIP-on-chip) was used to identify potential TCF7L2 target genes in INS-1

832/13 cells. The expression level of *Tcf7l2* and *Tp53inp1* in INS-1 832/13 cells was manipulated using siRNA and measured using qPCR. Apoptosis was measured using antibodies against Annexin V, and 7-AAD and visualized using confocal microscopy.
Results: The p53 pathway was identified as a key TCF7L2 target using ChIP-on-chip technology. SiRNA of *Tcf7l2* was subsequently used to verify the ChIP-on-chip results and a knock down of *Tcf7l2* (69.5 ± 0.04%) in INS-1 832/13 cells results in elevated *Tp53* (19.2 ± 0.05%) and *Tp53inp1* (52.6 ± 0.23%) mRNA levels. Interestingly, *TP53INP1* has recently been associated with increased risk of T2D. Upregulation of *Tp53* and *Tp53inp1* was associated with increased apoptosis in the beta cell line (3.92 ± 1.68 fold). *Tp53inp1* is a co-activater of Homeodomain interacting protein kinase 2 (HIPK2), which can specifically phosphorylate p53 on serine 46 and thereby induce apoptosis. A rescue experiment restoring (decreasing) the *Tp53inp1* expression level prevented the increase in apoptosis seen after *Tcf7l2* knock down, suggesting that the *Tcf7l2* effect required the p53 pathway and *Tp53inp1*.
Conclusion: The p53 pathway, particularly TP53INP1 seems to be central for mediating effects of TCF7L2 on apoptosis in beta cells. We thereby provide a link between two genes shown to increase risk of T2D, *i.e. TCF7L2* and *TP53INP1*.

Progression of beta cell dysfunction in Japanese type 2 diabetic patients in comparison with those who carry S20G mutation of islet amyloid polypeptide gene: a long-term follow-up study
S. Morita[1], S. Sakagashira[2], Y. Shimajiri[1], M. Furuta[1], T. Sanke[1];
[1]Department of Clinical Laboratory Medicine, [2]The First Department of Medicine, Wakayama Medical University, Japan.

Background and aims: Type 2 diabetic patients have islet amyloid deposition with considerably high frequency. Islet amyloid polypeptide (IAPP) was identified as a main constituent of the islet amyloid, and has been considered to be associated with pathophysiology or development of human type 2 diabetes due to its amyloidgenicity. We found S20G (AGC^{Ser} to GGC^{Gly}) mutation of *IAPP* gene, and have investigated that the G20-IAPP variant had stronger amyloidogenicity and cytotoxicity than wild type IAPP *in vitro*. However, there is little clinical data how impairments of insulin secretion progress in patients carrying S20G mutation. The long time course of the beta-cell function in type 2 diabetic patients also remains unknown. In this study, we first estimated the decline of insulin secretion in non-obese (BMI < 30 kg/m^2) Japanese type 2 diabetic patients without S20G mutation (T2D-patients), and then compared it with that of type 2 diabetic patients carrying S20G mutation (S20G-patients).
Materials and methods: We studied 70 T2D-patients and 6 S20G-patients. Patients with renal dysfunction (serum creatinine > 1.1 mg/dl) or those carrying anti-insulin antibodies were excluded. Serum C-peptide (CP) was employed as the indices for evaluation of endogenous insulin secretion, fasting level (F-CP), 5 min value after intravenous 1 mg glucagon injection (5'-CP), and 5 min increment from the basal after glucagon injection (d-CP). CP was measured by immunoenzymometric assay. The individual annual decline of endogenous insulin secretion (IAD) was calculated from the individual regression line between CP and duration (years after diagnosis). The estimated annual decline of endogenous insulin secretion (EAD) was calculated from regression line between total points of CP and duration (n=527 for F-CP, n=165 for 5'-CP and d-CP) in all T2D-patients (n=70), although it was a cross-sectional analysis. In T2D-patients, we used EAD of both 5'-CP and d-CP instead of IAD, because IAD of both 5'-CP and d-CP could not be calculated due to small number of the plots of each patient.
Results: IAD of F-CP was greater in S20G-patinets than T2D-patients (0.140±0.076 Vs 0.034±0.110 ng/ml/year, p=0.025). In T2D-patients, EAD was 0.031 ng/ml/year and it was almost same as IAD. IAD of both 5'-CP (n=4) and d-CP (n=4) in S20G-patients were high compared with those of EAD in T2D-patients (5'-CP: 0.202±0.096 Vs 0.101 ng/ml/year and d-CP: 0.118±0.056 Vs 0.062 ng/ml/year, respectively).
Conclusion: We showed the long-termed decline of the endogenous insulin secretion in non-obese Japanese T2D-patients. The results suggested that the decline of the endogenous insulin secretion is more rapid in S20G-patients than T2D-patients.

A common polymorphism in the ccl2 gene regulatory region affects mcp-1 gene expression and function of isolated non-diabetic and type 2 diabetic islets
S. Del Guerra[1], V. D'Aleo[1], G. Gualtierotti[1], F. Vistoli[2], F. Filipponi[3], U. Boggi[2], S. Del Prato[1], P. Marchetti[4], R. Lupi[5];
[1]Endocrinology and Metabolism, Metabolic Unit, [2]Oncology, Transplants and Advanced Technologies in Medicine, Division of Surgery in Uremic Patients, [3]Oncology, Transplants and Advanced Technologies in Medicine, Liver Transplant Unit, [4]Endocrinology and Metabolism, Division of Organ Transplantation and Cellular, University of Pisa, [5]Endocrinology and Kidney, Metabolic Unit, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy.

Background and aims: It has been shown that human islets release monocyte chemoattractant protein-1 (MCP-1), a macrophage chemokine which may impair the fate of the islets in vivo and after a transplant. In this study we evaluated presence and role of monocyte chemoattractant protein-1 (MCP-1) and its receptor CC -chemokine receptor-2 (CCR2) in isolated non-diabetic (Ctrl) and type 2 diabetic (T2DM) islets, including genotyping for a common polymorphism.
Materials and methods: Pancreatic islets were obtained from 47 Ctrl and 18 T2DM multiorgan donors. We evaluated glucose-stimulated insulin release (IR, μU/islet/min, expressed as Stimulation Index: SI), measured MCP-1, CCR2 and insulin mRNA expression, and analyzed the MCP-1 (-2518 G/A, rs1024611 in the promoter region) and the CCR2 (G46295A Val64Ile, rs1799864 in exon2) Single Nucleotide Polymorphisms (SNP).
Results: As expected, in T2DM islets SI (1.44±0.17) and insulin gene expression (7.15±1.5) were significantly reduced respect to Ctrl (2.34±0.20 and 26.47±6.64, respectively) islets (all p<0.001). MCP-1 and CCR2 expression was significantly higher in T2DM (3.80±0.62 and 0.31±0.05, respectively), respect to Ctrl (1.60±0.18 and 0.062±0.02, respectively) islets (all p<0.001). We observed a positive significant correlation between MCP-1 and CCR2 gene expression (R2=0.235, p=0.0032), a negative significant correlation between MCP-1 mRNA expression and both SI (R2=0.116, p=0.0095) and IR at 16.7 mmol/l glucose (R2=0.077, p=0.037), and a positive significant correlation between MCP-1 gene expression and BMI (R2=0.076, p=0.039). Both in Ctrl and in T2DM, we found that MCP-1 mRNA expression was significantly higher in CC and CT respect to TT genotype groups, with a SI significant lower in CC respect to TT genotype group. Intriguingly, islets presenting both SNPs studied (rs1799864 and rs1024611), showed a high MCP-1 and CCR2 gene expression and a reduced beta-cell function.
Conclusion: These data show that MCP-1 gene is present in human pancreatic islets, it's more expressed in T2DM respect to Ctrl islets, is regulated by the -2518 G/A polymorphism, and correlates with glucose-stimulated insulin release. The study of MCP-1 expression and genotype could be useful also in understanding the inflammatory response in vivo against pancreatic islets after transplantation.

PS 5 Candidate genes in type 2 diabetes

Relationship between adiponectin and insulin-like growth factor-binding protein 1 and their combined effects in type 2 diabetes

T. Gu[1], L. Kärvestedt[1,2], K. Brismar[1], H.F. Gu[1];
[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, [2]Stockholm Sjukhem, Sweden.

Background and aims: Evidence has demonstrated that serum levels of adiponectin (AdipoQ) and insulin-like growth factor-binding protein 1 (IGFBP-1) are decreased in type 2 diabetes (T2D) patients compared to non-diabetic control subjects. *AdipoQ* genetic polymorphisms are found to be associated with T2D. *IGFBP-1* genetic polymorphisms are associated with impaired renal function in T2D. However, whether adiponectin and IGFBP-1 have gene-gene and protein-protein interactions in T2D is unknown. In the present study, we attempted to explore possible relationship between these two molecules and their effects in T2D.
Materials and methods: We genotyped five SNPs (-11426A/G, -11391G/A, -11377C/G, +45T/G Gly15Gly and +276A/C) in the *AdipoQ* gene and two SNPs (-575G/A and +4403A/G Ile253Met) in the *IGFBP-1* gene in 163 Swedish T2D patients. Of the patients, 85 had family history of diabetes (FHD). We also measured serum levels of adiponectin and IGFBP-1 in all patients by using radio-immunoassays. We further employed generalized multifactor dimensionality reduction (GMDR) to assess the impact of gene-gene interactions (the patients without FHD as controls). Linear regression and logistic regression models were used for correlation analyses of adiponectin and IGFBP-1 serum levels and for confirmation of the data from GMDR analyses.
Results: We found that serum adiponectin levels in T2D-FHD(+) (4.47 mg/l, geometrical means 4.07-4.90) was significantly lower compared to T2D-FHD(-) (5.50 mg/l, 4.90-6.17) (P=0.006). GMDR analyses of all studied SNPs between the *AdipoQ* and *IGFBP-1* genes implicated that two promoter polymorphisms -11377C/G in the *AdipoQ* gene and -575G/A in *IGFBP-1* had an impact of gene-gene interaction (P=0.054, cross-validation consistency 10/10 and testing accuracy 59.9%). Further analyses indicated that there was a significant correlation between adiponectin and IGFBP-1 at protein levels in T2D-FHD(-) (R=0.268, P=0.023) but not in T2D-FHD(+) (P=0.167). Among T2D-FHD(-) carrying with GG and CG genotypes of *AdipoQ* -11377C/G polymorphism, this correlation between adiponectin and IGF-BP1 was remained (R=0.414, P=0.023) but not presented in T2D-FHD(-) with CC genotype (P=0.295). Similarly, serum levels of adiponectin and IGFBP-1 were significantly correlated (R=0.303, P=0.047) in T2D-FHD(-) carrying with AA and GA genotypes of IGFBP1 -575G/A polymorphism, but not in T2D-FHD(-) with GG genotype (P=0.374).
Conclusion: Data from the present study implicate that promoter polymorphisms of the *AdipoQ* and *IGFBP-1* genes may have an impact of gene-gene interaction in T2D. These two promoter polymorphisms may influence the correlation between adiponectin and IGFBP-1 at protein levels. Replication study with additional T2D patients and non-diabetic control subjects will be conducted to further understand genetic and functional effects of adiponectin and IGFBP-1 in the development of T2D.

Circulating HMW adiponectin is positively correlated and shares a common genetic background with urinary albumin excretion in non diabetic white caucasians from Italy

C. Menzaghi[1], L. Salvemini[1], C. De Bonis[1], D. Mangiacotti[1], G. Fini[1], V. Trischitta[1,2], S. De Cosmo[3];
[1]Research Unit of Diabetes and Endocrine Diseases, IRCCS, San Giovanni Rotondo, [2]University "Sapienza", Rome, [3]Unit of Endocrinology, IRCCS, San Giovanni Rotondo, Italy.

Background and aims: Circulating levels of adiponectin, an insulin sensitizing hormone, have been reported to be paradoxically increased in patients with higher urine albumin excretion (UAE), a condition characterized by insulin resistance. In order to avoid the possible confounding effects exerted in these previous studies by the presence of diabetes - and related treatments - and that of reduced kidney function, we investigated the relationship between adiponectin and UAE levels in a large (n = 640, 246M/394F), family-based sample of relatively young (age 40.3 ± 14.5 yrs) non diabetic, White Caucasians from Italy without known kidney impairment who were not on any pharmaceutical treatment.
Materials and methods: UAE was measured by nephelometric method and reported as urinary albumin-creatinine ratio (ACR). Serum adiponectin (high, medium and low molecular weight isoforms; HMW, MMW, LMW) levels were measured by ELISA. Glomerular filtration rate was estimated by the reciprocal of serum cystatin C (CC) expressed in mg/L multiplied by 100 (CC-GFR; mean: 125.4 ± 35.9). Five SNPs in the *ADIPOQ* gene, previously reported to be associated to adiponectin levels and/or diabetic nephropathy (rs182052, rs17300539, rs2241766, rs1501299 and rs677395) were genotyped. A linear mixed effects model was used to assess both phenotypic correlations and to test associations. Bivariate analyses were conducted to study genetic correlations between adiponectin isoforms and UAE.
Results: ACR levels (median: 0.53 mg/mmol; range 0.06 - 12.4) were directly associated with HMW adiponectin ($\beta \pm SE = 0.058 \pm 0.02$, $p = 3.7 \times 10^{-3}$). Further adjustment for CC-GFR, did not significantly change this association ($\beta = 0.06 \pm 0.02$, $p=2.7 \times 10^{-3}$). A significant genetic correlation (rhog = 0.38 ± 0.20; p=0.04) was observed between ACR and HMW adiponectin. Among the *ADIPOQ* SNPs tested, rs17300539, which was associated with both HMW ($p = 4.4 \times 10^{-5}$) and ACR ($p=2.7 \times 10^{-3}$), partially accounted for this genetic correlation (2.5%).
Conclusion: In conclusion, circulating HMW adiponectin and UAE levels are directly correlated and share, at least partly, a common genetic background, involving the *ADIPOQ* locus for a small proportion of it.

Associations of common variants of ADIPOQ, ADIPOR1 and ADIPOR2 with adiponectin concentration and diabetes incidence in the Diabetes Prevention Program

K.J. Mather[1], C.A. Christophi[2], K.A. Jablonski[2], W.C. Knowler[3], R.B. Goldberg[4], S.E. Kahn[5], F.X. Pi-Sunyer[6], T.I. Pollin[7], J.C. Florez[8], P.W. Franks[9], for the Diabetes Prevention Program Research Group;
[1]Indiana University School of Medicine, Indianapolis, [2]The George Washington University Biostatistics Center, Rockville, [3]National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, [4]The University of Miami Miller School of Medicine, Miami, [5]Veterans Affairs Puget Sound Health Care System, Seattle, [6]St. Luke's-Roosevelt Hospital, New York City, [7]University of Maryland School of Medicine, Baltimore, [8]Center for Human Genetic Research, Massachusetts General Hospital, Boston, USA, [9]Umea University Hospital, Umea, Sweden.

In the Diabetes Prevention Program, a trial enrolling people from multiple ethnic backgrounds who were overweight and had impaired glucose regulation, baseline concentrations of adiponectin were independently predictive of incident type 2 diabetes. We examined the association of genetic variation in the genes encoding adiponectin (*ADIPOQ*) and the two known adiponectin receptors (*ADIPOR1*, *ADIPOR2*) with circulating adiponectin concentrations and with diabetes incidence. Fourteen of 24 *ADIPOQ* SNPs were nominally associated with adiponectin concentrations; 9 exceeded experiment-wide significance and 4 exceeded genome-wide significance in the entire study population (rs1648707 $p=10^{-15}$; rs17366568 $p=10^{-14}$; rs6810075 $p=10^{-11}$; rs182052 $p=10^{-12}$). For these 4 SNPs, minor allele homozygotes had 11-25% lower mean circulating concentration of adiponectin than major allele homozygotes. Among white subjects only (n=1622) these SNPs showed similar patterns of association (rs1648707 $p=10^{-11}$; rs17366568 $p=10^{-14}$; rs6810075 $p=10^{-9}$; rs182052 $p=10^{-10}$), indicating that these signals are not confounded by population stratification. One *ADIPOR1* SNP (rs10800890) was also associated with adiponectin concentrations ($p=10^{-4}$); no *ADIPOR2* SNPs were associated with adiponectin concentrations. Three of 22 *ADIPOR1* SNPs and 2 of 31 *ADIPOR2* SNPs were associated with diabetes incidence in the whole population ($p=10^{-2}$ to 10^{-3}). None of the *ADIPOQ* variants, and specifically none of those associated with adiponectin concentrations, was associated with diabetes incidence in the whole study population. Two of the 77 evaluated SNPs interacted with treatment to influence diabetes incidence in the whole study population (*ADIPOQ* rs17373414 p=0.04, hazard ratio higher in lifestyle than placebo; *ADIPOR2* rs758027 p=0.01, hazard ratio higher in metformin than placebo). A parallel rs758027 interaction was evident among whites, again arguing against confounding by population stratification. *ADIPOQ* SNPs are significantly associated with adiponectin concentrations in the DPP cohort, confirming the results published from cohorts with lower

diabetes risk and expanding them to a multi-ethnic population with impaired glucose regulation. Despite associations with circulating adiponectin concentrations and the known robust relationship between adiponectin concentrations and diabetes risk in this cohort, loci influencing diabetes risk did not overlap with those influencing adiponectin concentrations in the DPP. This highlights the complex relationships of genetic and non-genetic determinants of adiponectin concentrations with type 2 diabetes risk.

Effect of variants in the RORA gene on risk of type 2 diabetes
A. Jonsson[1], S. Alkayyali[1], B. Isomaa[2,3], T. Tuomi[2,4], L. Groop[1], V. Lyssenko[1];
[1]Clinical Sciences, Diabetes & Endocrinology, Lund University, Malmö, Sweden, [2]Folkhälsan Research Centre, Helsinki, [3]Malmska Municipal Health Care Center and Hospital, Jakobstad, [4]Medicine, Helsinki University Central Hospital and University of Helsinki, Finland.

Background and aims: A genetic variation in the RAR-related orphan receptor alpha (ROR-α) gene (*RORA*) was found to be associated with reduced insulin secretion in the DGI genome wide association study for early insulin secretion. ROR-α has been previously implicated in glucose and lipid metabolism. The aim of the study is to validate the effect of genetic variants in *RORA* on insulin secretion, and to explore its effects on risk for type 2 diabetes (T2D) and related phenotypes.
Materials and methods: Six *RORA* variants (rs10519116, rs11071557, rs17204545, rs2414689, rs4774389 and rs4775292) were genotyped in three cohorts, totaling 13,560 Scandinavian individuals (Malmö Case Control [MCC], n=6,380; Prevalence, prediction and prevention of diabetes in Botnia [PPP], n=4,852, and Botnia Prospective Study [BPS], n=2,328 with a median follow-up period of 7.6 years).
Results: In the DGI, the T-allele of rs4775292 was associated with reduced insulin secretion (N=1,018, beta (sem) -0.214 (0.041), P=0.0024). Furthermore, in the independent follow-up PPP study the same allele showed increased insulin secretion in young (N=1,499, 0.103 (0.031), P=0.00079), but decreased in elderly (N=1,245, -0.081 (0.030), P=0.0073, median age 50 yrs as cut-off). Combined analysis confirmed association of the T-allele of rs4775292 with reduced insulin secretion in elderly individuals (N=2,698, -0.075 (0.023), P=0.0011). In the MCC, in line with increased insulin secretion, the T-allele of rs4775292 was associated with protection from T2D (OR [95%CI]: 0.78 [0.61-0.99], P=0.039) in young, but no effect was seen (1.00 [0.91-1.11], P=0.94) in elderly. Of note, in the MCC, the C-allele of another SNP, rs10519116, was more frequent in cases than in controls (26.5% vs. 24.2%, P=0.015). This difference was more pronounced in elderly individuals (27.0% vs. 24.0%, P=0.0027), which translated into an age, sex and BMI adjusted OR for T2D of 1.16 [1.03-1.29], P=0.011. The same C-allele of rs10519116 and also the T-allele of rs4775292 were associated with increased 2hr proinsulin and GIP levels during OGTT (rs10519116: 0.081 (0.036), P=0.024 and 0.119 (0.037), P=0.0014; rs4775292: 0.080 (0.030), P=0.0079 and 0.105 (0.031), P=0.00091) in male PPP participants. Furthermore, the same T-allele of rs4775292 and the GT/TT-genotype of rs11071557 were associated with decreased HDL and APOA1 both at baseline (rs4775292: -0.037 (0.014), P=0.0087 and -2.77 (1.00), P=0.0059; rs11071557: -0.183 (0.057), P=0.0015 and -14.43 (4.08), P=0.00042) and at follow-up (rs11071557: -0.203 (0.075), P=0.0071 and -11.17 (4.98), P=0.025) in male BPS participants. Finally, two SNPs were associated with decreased insulin sensitivity (rs17204545: PPP -0.053 (0.020), P=0.0079 and rs2414689: BPS -0.077 (0.026), P=0.0026) in male participants. Interestingly, *RORA* shows a rich methylation pattern where rs4775292 is a candidate for a CpG site. Methylation studies are ongoing to provide insights whether they can explain the age effect on insulin secretion and risk of T2D.
Conclusion: These results suggest that genetic variants in the *RORA* gene are associated with increased risk of T2D, and influence glucose and lipid metabolism.

Vaspin is involved in the pathophysiology of type 2 diabetes by regulating insulin sensitivity
J. Breitfeld[1], N. Klöting[2], J.T. Heiker[3], U. Enigk[1], M. Kern[2], Y. Böttcher[2], D. Schleinitz[1], K.E. Dietrich[1], N. Wiele[2], A. Tönjes[2], A.G. Beck-Sickinger[3], M. Stumvoll[2], M. Blüher[2], P. Kovacs[1];
[1]Interdisciplinary Centre for Clinical Research, [2]Department of Medicine, [3]Institute of Biochemistry, University of Leipzig, Germany.

Background and aims: Visceral adipose tissue derived serine protease inhibitor (vaspin) is a novel adipokine that may link obesity, insulin resistance (IR) and type 2 diabetes (T2D), but so far its pathophysiological role remains largely unknown. The first aim was to study the effects of recombinant vaspin treatment on insulin sensitivity in *db/db* mice. In addition, we investigated the role of genetic variation in the human vaspin gene in the pathogenesis of T2D.
Materials and methods: Animal studies: After recombinant vaspin administration (1mg/kg body weight i.p.; at 6 pm and at 6 am prior to the tests), we performed glucose tolerance tests (2g/kg body weight i.p.) and hyperinsulinemic-euglycemic clamps in *db/db* mice (N=5 for each test). Human genetic studies: *Vaspin* (exons, exon-intron boundaries, 5′ and 3′ UTRs) was sequenced in DNA samples from 48 unrelated Caucasian subjects (ABI PRISM 3100 Avant; Applied Biosystems Inc.). Six single nucleotide polymorphisms (SNPs) identified by sequencing and 22 haplotype tagging SNPs representative for their linkage disequilibrium groups (r^2>0.8 and minor allele frequencies >0.05) were genotyped in 1046 clinically well-characterized Sorbs from Germany for subsequent association studies on metabolic traits including insulin resistance and secretion indices (e.g. fasting Belfiore, Stumvoll index, HOMA-IR) based on glucose tolerance test in non diabetic subjects. *P* values <0.05 were considered to be of nominal statistical significance. For *in vitro* analyses of the effects of the stop codon mutation (p.R211X), full-length (wild type) and short-length (carrying the mutation) *vaspin* was cloned into p3xFLAG-myc-CMV™ expression vector (Sigma-Aldrich) and transfected into HEK-cells (Fugene® HD Transfection Kit; Roche). Proteins were detected by western blot.
Results: Animal studies: Vaspin administration in *db/db* mice resulted in improved glucose tolerance (P<0.05). Consistently, glucose infusion rate (GIR) during the steady state of the clamp significantly increased after vaspin treatment (P<0.05). Human genetic studies: Sequencing of the vaspin gene revealed one SNP (rs61757459) in exon 3 resulting in a STOP-codon (p.R211X). Western blot experiments showed that full-length and short-length vaspin were expressed in eukaryotic cells. Short-length vaspin yielded in a prominent ~25-kDa band. Several SNPs were nominally associated with WHR (waist-to-hip-ratio), 30min glucose levels or 2-hr-insulin levels (adj. for age, sex and BMI). Furthermore one SNP (rs2236242) showed additional associations with $AUC_{Glucose}$, insulin sensitivity and insulin resistance indices.
Conclusion: In conclusion, our data demonstrate the substantial insulin sensitizing effect of vaspin and suggest a role of *vaspin* genetic variants in the pathophysiology of insulin resistance and T2D.

ABO blood groups and incidence of type 2 diabetes in men and women
L. Qi[1], Y. Song[2], J. Manson[2], F.B. Hu[1];
[1]Nutrition and Epidemiology, Harvard School of Public Health, Boston, [2]Department of Medicine, Harvard Medical School, Boston, USA.

Background and aims: Previous small studies associated ABO blood types with the prevalence of diabetes. Recent genome-wide scans identified *ABO* locus might determine various risk factors for type 2 diabetes.
Materials and methods: We prospective examined the relationship between ABO blood types and the risk of incident type 2 diabetes in men and women from two cohorts: the Health Professionals Follow-up Study (HPFS) and the Nurses' Health Study (NHS).
Results: In the HPFS, during 452,404 person-years of follow-up, 1,764 participants developed type 2 diabetes. Compared with participants with blood group O, the relative risk (RR) associated with blood group A, B, and AB were 1.08 (95% confidence interval [CI] 0.97-1.20), 1.15 (1.00-1.34), and 1.31 (1.10-1.57). In the NHS, during 111,7247 person-years of follow-up, 4,376 participants developed type 2 diabetes. Compared with participants with blood group O, the RRs (95% CI) of type 2 diabetes associated with blood groups A, B, and AB were 1.10 (1.03-1.18), 1.03 (0.94-1.13), and 1.02 (0.91-

1.15), adjusting for traditional risk factors. The association of blood group A with diabetes risk was more evident in postmenopausal than premenopausal women. Overall, as compared with O blood group, the non-O blood group (blood group A, B, or AB) was associated with 12% (2-24%) and 7% (1-14%) increased diabetes risk in men and women; respectively; and was associated with 9% (4-15%) increased diabetes risk in the combined samples. The population attributable risk (PAR) for type 2 diabetes due to non-O blood group was 4.7%.
Conclusion: ABO blood types were significantly associated with the risk of type 2 diabetes. Non-O blood groups were associated with an increased risk of diabetes in both genders. The associations of specific blood groups with diabetes risk showed a gender difference.

Contribution of mother and father in the familiar transmission of type 2 diabetes mellitus according to the proband's gender
F.L. Cavalot, P. Poy, A. Pomero, A. Pagliarino, P. Massucco, M. Trovati;
Dept of Clinical and Biological Sciences, Faculty of Medicine San Luigi Gonzaga, University of Turin, Orbassano, Italy.

Background and aims: Type 2 diabetes mellitus (T2DM) shows strong familiar aggregation: the relative role of maternal and paternal familiarity, however, needs to be further investigated. In this study, we evaluated the distinct contribution of the mother and the father in T2DM transmission according to proband's gender.
Materials and methods: We evaluated through a structured interview the familial transmission in 1076 T2DM patients aged <70 years attending our Diabetes Clinic, divided into two groups according to the age at diagnosis: 30-49 years (Group A: 540 consecutive patients, M/F: 366/174) and 50-69 years (Group B: 536 consecutive patients, M/F: 312/224).
Results: Group A showed the following parental transmission: only mother: 34.6%; only father: 19.8%; both parents: 10.7%. Thus, mother was affected in 45.3%, father in 30.5% (p<0.0001). When proband's gender was considered, parental transmission was: a) in men (n=366): only mother: 34.2%; only father: 22.4%; both parents: 7.7%. Thus, mother was affected in 41.9%, father in 30.1% (p<0.018); b) in women (n=174): only mother: 35.6%; only father: 14.4%; both parents: 17.2%. Thus, mother was affected in 52.8%, father in 31.6% (p<0.004). Thus, the excess of maternal transmission was present in both genders, but women probands showed an increased probability to have both parents affected (p=0.026); furthermore, in the presence of father affected, the conditional probability to have also mother affected was greater in women than in men (55% vs 25%, p=0.007). Familiarity was not modified by proband's body mass index. In Group B, parental transmission was less frequent than in Group A, mother being affected in 35.7% vs 45.3% in Group A (p=0.023), father in 14.8% vs 30.5% in Group A (p<0.0001). Also in Group B, however, mother was more frequently affected than father (p<0.0001). By considering the two groups together, multivariate linear regression showed that, in comparison to the absence of familiarity in parents: a) in men probands, familiarity in the mother anticipated diabetes diagnosis 2.6±0.7 yrs (p<0.0001), in the father 5.1±0.9 yrs (p<0.0001) and in both parents 9.1±1.4 years (p<0.0001); b) in women probands, familiarity in the mother anticipated diabetes diagnosis 2.2±1.0 yrs (p=0.023), in the father 2.5±1.3 yrs (p=0.065) and in both parents 7.2±1.5 yrs (p<0.0001). Thus, familiarity in the father anticipated the diagnosis of T2DM more strongly in men than in women. Men excess in both Group A and Group B induced us to compare our data with the percentage of men in T2DM patients aged < 70 years living in the District in which our Hospital is located, obtained from the Health Service data of our Region: this percentage was 65% (vs 68% in Group A) in patients with diabetes diagnosis at age 30-49 years and 57% in those with diabetes diagnosis at age 50-69 years (vs 58% in Group B). Thus, an excess of diabetic men vs women was present in our District, independently from attendance at our Diabetes Clinic.
Conclusion: In Type 2 diabetes: i) familiarity predicts early diagnosis; ii) maternal transmission is stronger than the paternal-one in both proband genders independently of age at diagnosis; iii) if father is affected, maternal co-transmission is more frequent in women.

***TCF7L2* and therapeutic response to sulfonylureas in patients with type 2 diabetes**
M. Hahn[1], A. Körner[2], M. Stumvoll[3], P. Kovacs[4], A. Holstein[1];
[1]1st Department of Medicine, Klinikum-Lippe, Detmold, [2]University Hospital for Children and Adolescents, University of Leipzig, [3]Department of Medicine, University of Leipzig, [4]Interdisciplinary Centre for Clinical Research, University of Leipzig, Germany.

Background and aims: Variants in the *TCF7L2* have been shown to be associated with an increased risk for type 2 diabetes (T2D). Since the association with diabetes could be explained by effects on insulin secretion, we investigated whether patients with diabetes risk alleles at rs7903146 might have an altered hypoglycaemic response to sulfonylureas (SUs).
Materials and methods: We recruited 189 patients with T2D being treated with SUs and determined the rs7903146 diabetes risk genotype. We used a logistic regression with secondary SU failure defined as the addition of insulin after at least 6 months of SU therapy and corresponding A1C measurement of ≥7.0%.
Results: In univariate regression analyses, *TCF7L2* genotype and diabetes duration were the main predictors of SU treatment failure. The rs7903146 T-allele was significantly more frequent in the group of patients additionally treated with insulin (40%) than in the control group treated only with SUs (28 %) [*P*=0.03; odds ratio: 1.73 (1.06-2.84) in an additive mode of inheritance]. The genotype effect was independent of diabetes duration.
Conclusion: Our data suggest that patients with diabetes risk alleles in *TCF7L2* have an altered hypoglycaemic response to SUs resulting in early secondary failure, thus supporting previously reported findings and indicating the potential of pharmacogenomics in the therapy of T2D.

The role of genetic variation in the sodium-glucose cotransporter 2 gene (*SGLT2*) in the pathophysiology of type 2 diabetes
D. Schleinitz[1], U. Enigk[1], J. Breitfeld[1], B. Enigk[1], K. Dietrich[1], I. Müller[2], J. Halbritter[2], A. Fischer-Rosinsky[3,4], A.H. Pfeiffer[3,4], J. Spranger[3,4], M. Stumvoll[2], P. Kovacs[1], A. Tönjes[2];
[1]IZKF Leipzig, University of Leipzig, [2]Department of Medicine, University of Leipzig, [3]Department of Endocrinology, Diabetes and Nutrition, Charité-Universitätsmedizin Berlin, [4]Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbrücke, Nuthetal, Germany.

Background and aims: The sodium-glucose cotransporter 2 (SGLT2) is the major cotransporter involved in glucose reabsorption in the kidney. Mutations in the *SGLT2* gene cause renal glucosuria and are associated with reduced circulating glucose levels. Treatment with SGLT2-inhibitors results in decreased fasting glucose levels, reduction of HbA1c and lower BMI. We therefore investigated the effects of common genetic variation in *SGLT2* on glucose traits and BMI in non-diabetic subjects as well as the association with type 2 diabetes (T2D).
Materials and methods: Four HapMap tagging single nucleotide polymorphisms (SNPs) (www.hapmap.org) were genotyped (TaqMan, Applied Biosystems, Inc.) for subsequent association studies on BMI, T2D and related metabolic traits in 1046 Sorbs from Germany who had undergone a detailed phenotyping. The SNPs were representative of their linkage disequilibrium groups and were selected according to r^2>0.8 and minor allele frequency >0.01. An independent cohort from Berlin, Germany (N=2046, including 359 subjects with T2D) was taken for replication.
Results: In a case control study including 106 patients with T2D and 786 controls with normal glucose tolerance, none of the SNPs showed association with T2D. However, rs9934336 was nominally associated with 30 min plasma glucose, 2 hr insulin concentrations and incremental $AUC120_{glucose}$ during oral glucose tolerance test in 892 non-diabetic subjects (P<0.05 in additive model adjusted for age, sex and BMI). Carriers of the rs9934336 G-allele had higher 30 min plasma glucose and 2 hr insulin concentrations. The SNP showed no association with T2D in the Berlin cohort, but was, however, nominally associated with 60 min plasma glucose (adjusted P<0.05) and showed consistent effect on $AUC120_{glucose}$ in a subgroup of subjects with impaired fasting glucose and impaired glucose tolerance (N=485).

Conclusion: In conclusion, our data suggest a role of *SGLT2* genetic variation in the regulation of insulin and glucose levels in non-diabetic individuals. *SGLT2* polymorphisms might therefore be potential candidates in pharmacogenomic studies investigating the interaction between these genetic variants and the efficacy of antidiabetic treatment based on inhibition of SGLT2.

ENPP1 expression and metformin efficacy in type 2 diabetes

O. Ludovico[1], M.G. Farina[2], S. Prudente[3], A.P. Palena[1], V. Proto[3], V. Marotta[2], L. Frittitta[2], V. Trischitta[1,3];
[1]Endocrinology, IRCCS "CSS", San Giov. Rotondo, [2]Intern Med, Univ.of Catania, [3]IRCCS "CSS"-Mendel, Roma, Italy.

Background: ENPP1 is an inhibitor of insulin signalling whose overexpression plays a role on insulin-resistance. Also the *ENPP1* K121Q polymorphism has been associated with insulin resistance, with the Q121 variant being a gain of function substitution which increases the protein inhibitory activity on insulin signalling. Metformin (Met) is an insulin-sensitizer, established as "first choice" oral hypoglycemic agent (OHA) in type 2 diabetes (T2D). In the Diabetes Prevention Program (DPP) study, the efficacy of Met in preventing future T2D was significantly greater in Q121 carriers (individuals carrying KQ or QQ genotypes) as compared to those carrying the KK genotype, thus suggesting that higher ENPP1 inhibitory activity predicts higher metformin efficacy.
Aims: to investigate i) whether ENPP1 expression predicts the efficacy of 3-month metformin monotherapy on fasting glucose (FG) in patients with T2D; ii) whether Met modulates ENPP1 expression in peripheral blood mononuclear cells (PBMC).
Methods: 55 patients (31 M/24 F; age: 40-70 yrs; disease duration: 2-25 yrs; HbA_{1c}: 6.5-9%; no need of insulin therapy) were recruited. Contraindications to Met treatment were considered as exclusion criteria. Previous OHA were discontinued for 5 days and then Met (2550 mg/daily) was given. Body mass index (BMI), HbA_{1c}, glucose, insulin, insulin-resistance HOMA index, triglycerides and HDL-cholesterol were measured at baseline and 12 weeks after Met treatment. ENPP1 expression levels were measured by quantitative RT-PCR in PBMC before and after treatment.
Results: ENPP1 baseline expression was significantly and directly correlated with Met efficacy as indicated by change in FG after treatment (i.e. baseline FG minus 3-month FG) (adjusted R2=0.09, p=0.015). Of all other measured variables, only baseline FG was able to predict Met efficacy (adjusted R2=0.33, p<0.0001). Of note, ENPP1 maintained a significant prediction ability also when adjusted for baseline FG (p=0.045) as well as when also sex, BMI and duration of T2D were added into the model (p=0.04). Average ENPP1 expression levels didn't change after Met treatment (6.94±6.14 arbitrary units and 7.66±5.78, before and after, respectively; p=0.173).
Conclusion: Our data indicate that Met efficacy is higher in individuals with higher ENPP1 expression and then, presumably characterized by higher ENPP1 inhibitory effect on insulin signalling. These data are very much along the same line of those from the DPP study showing increased metformin efficacy in carriers of *ENPP1* Q121 variant. A better understanding of these phenomena could help setting up strategies aimed at predicting Met efficacy.

Cyp2c8 variant reduce the therapeutic response to thiazolidinediones - a godarts study

K. Zhou, L. Burch, S. Vella, C.N.A. Palmer, E.R. Pearson;
Biomedical Research Institute, Dundee, United Kingdom.

Background and aims: The reason for highly variable glycaemic response to thiazolidinediones (TZDs) is poorly understood. TZDs are mainly metabolized by the cytochrome p450 2C8 enzyme encoded by CYP2C8. Two common CYP2C8 variants *3 and *4 are associated with greater clearance and lower plasma concentrations of TZDs. We hypothesised that patients carrying these variants would have reduced glycaemic response to thiazolidinediones.
Materials and methods: Linear and logistic regressions were used to model HbA_{1c} reduction and achieving a treatment target of HbA_{1c} <7% in 374 patients from the GoDARTS cohort in Tayside, Scotland. Parameters included are age, gender, BMI, baseline HbA_{1c}, adherence and CYP2C8 genotype.
Results: Compared to the wild-type carriers, model adjusted HbA_{1c} reduction was 0.8% lower in those patients who carry two functional variant alleles (p=0.001). These patients were also 3.8 times more likely to fail achieving treatment target (p=0.06).
Conclusion: In keeping with the pharmacokinetic role of this gene, our data suggest CYP2C8 variants have a marked impact on glycaemic response.

Resistance to exercise-induced changes in the global DNA methylation pattern of skeletal muscle in individuals with a family history of type 2 diabetes

M. Dekker Nitert, T. Dayeh, S. Lang, T. Elgzyri, B. Yang, O. Hansson, T. Rönn, K.-F. Eriksson, L. Groop, C. Ling;
Lund University Diabetes Centre, Malmö, Sweden.

Background and aims: First degree relatives of individuals with type 2 diabetes (T2D) have an increased risk of developing the disease. This is conferred by genetic and shared environmental factors, not least physical inactivity, as physical activity is known to improve glucose homeostasis. However, it is unknown if epigenetic changes contribute to the increased risk of T2D. Whether physical exercise can affect methylation of genes of importance for the abnormal glucose metabolism characteristic of individuals with a genetic predisposition to T2D is not known. This study examines the global changes in DNA methylation in skeletal muscle in humans with or without a family history of T2D before and after a six-month exercise intervention.
Materials and methods: 16 men with (FH+) and 13 men without (FH-) a first-degree family history of T2D, matched for age, BMI and VO2max, participated in a supervised six-month exercise intervention study. Biopsies from the vastus lateralis muscle were obtained before and after the exercise intervention. DNA was isolated and MeDIP-Chip was performed e.g. 1 µg DNA was immunoprepitated with a monoclonal antibody against methylated cytosine and hybridized to the NimbleGen 2.1 DeLuxe Array containing 2.1 million probes covering a 10 kB region of all genes, with 7.5 kB upstream and 2.5 kB downstream of the transcription start site in addition to all known CpG islands.
Results: Before exercise, 1891 genes displayed lower methylation and 1237 genes showed higher methylation in skeletal muscle from FH+ vs FH- individuals. Exercise increased methylation of 1402 and decreased methylation of 2136 genes in the whole chohort. Notably, exercise changed methylation of fewer genes in FH+ than in FH- subjects (1085 vs 2355 genes increased, and 2035 vs 3281 decreased methylation) with little overlap between the top 100 genes of the two groups.
Conclusion: Human skeletal muscle of individuals with a family history of T2D is partially resistant to epigenetic changes induced by exercise in individuals with no T2D heredity.

Does macronutrient intake or physical activity level interact with genetic risk for increased fasting glucose?

G. Hindy[1], E. Sonestedt[1,2], A. Sharma[1], M. Orho-Melander[1];
[1]Department of Clinical Sciences, Diabetes and Cardiovascular Disease, Genetic Epidemiology, Sweden, [2]Nutrition Epidemiology, Lund University Diabetes Centre, Lund University, Malmö, Sweden.

Background and aims: The prevalence of type 2 diabetes (T2D) is drastically increasing around the globe and is believed to be linked to the adoption of a western lifestyle mainly in terms of dietary habits and physical inactivity. Genome-wide association studies (GWAS) have identified several single nucleotide polymorphisms (SNPs) associated with fasting glucose (fGLU) levels and T2D. The aim of this study was to investigate if a combined effect of 15 SNPs previously shown to associate with fGLU levels in GWAS interacts with dietary intakes or physical activity level on fasting glucose levels in the population based Malmö Diet and Cancer Study- Cardiovascular cohort (MDC-CV).
Materials and methods: The 15 SNPs identified in or near *G6PC2, MTNR1B, GCK, DGKB-TMEM195, GCKR, ADCY5, MADD, CRY2, ADRA2A, PROX1, SLC2A2, GLIS3, SLC30A8, FAM148B,* and *TCF7L2* were genotyped by taqman in MDC-CV. After excluding all patients with diabetes, individuals without diet-data and those with incomplete genotype information we included 4615 individuals in the study (41% males, age 57±6 years, BMI 26±4 kg/m^2, fGLU 5.7±0.8 mmol/l). A fGLU genetic risk score (fGLU-GRS) was

created summing the number of fGLU increasing alleles of the 15 SNPs. Assuming additive model and adjusting for age and sex we analysed association between fGLU-GRS and fGLU. Association between GRS and fGLU was evaluated in strata of gender-specific tertiles according to percentage of energy from macronutrients as well as physical activity score. Interaction between dietary factors or physical activity and fGLU-GRS was assessed by introducing a multiplicative factor with continuous variables adjusting for age, sex, season and total energy intake.
Results: The fGLU-GRS was strongly associated with fGLU (p=5.8e-15) with a mean effect size of 0.04 mmol/l per each glucose increasing allele. Similar associations were found in males (p=1.7e-6) and females (p=2.4e-10). Individuals in the highest fGLU-GRS quintile had 0.26 mmol/l higher fGLU compared to those in the lowest quintile. The effect sizes of each fGLU increasing alleles were 0.04, 0.06 and 0.02 mmol/l within low, medium and high carbohydrate intake tertiles (p=0.11, p=0.09 and p=0.71 for interaction in all, males and females, respectively); 0.05, 0.04 and 0.04 mmol/l within low, medium and high fiber intake tertiles (p=0.27, p=0.50 and p=0.43) and 0.02, 0.05 and 0.04 mmol/l in low, medium and high fat intake tertiles (p= 0.23, p=0.16 and p=0.89). The mean effect size of each fGLU increasing allele was 0.4 mmol/l in all physical activity tertiles (p=0.84, p=0.50 and p=0.65 for interaction in all, males and females, respectively).
Conclusion: GRS of 15 fGLU SNPs associated strongly with fGLU in a population based Swedish sample. Our study did not reveal significant interactions between such genetic susceptibility and macronutrient intakes or physical activity level. We believe that larger sample sizes and taking into account the quality of dietary carbohydrates and fat need to be taken into account in future studies to exclude such interactions.

Body mass index is a potential modifier of the influence on beta cell function exerted by SLC30A8 and KCNJ11 diabetes risk variants in patients with newly diagnosed type 2 diabetes
M. Trombetta[1], S. Bonetti[1], F. Turrini[1], L. Boselli[1], E. Trabetti[2], G. Malerba[2], P.F. Pignatti[2], M. Muggeo[1], E. Bonora[1], R.C. Bonadonna[1];
[1]Department of Medicine, [2]Department of Life and Reproduction Sciences, University of Verona, Italy.

Background and aims: The zinc transporter, SLC30A8, and the potassium channel, KCNJ11, are both expressed in the beta cell and are involved in insulin transport and secretion. The rs13266634 G allele in SLC30A8 and the rs5219 A allele in KCNJ11 are associated with type 2 diabetes (T2D) risk and with reduced beta cell function (BF) in non-diabetic subjects. We evaluated the role of these two non-synonymous polymorphisms in determining clinical and pathophysiological traits in patients with newly diagnosed type 2 diabetes.
Materials and methods: 456 GAD-negative and drug-naive patients (age 57.8±10.3 years, BMI 29.9±5.1 kg/m^2, HbA1c 7.0±1.4 %) with newly diagnosed type 2 diabetes underwent standard clinical characterization. BF and insulin sensitivity (SI) were assessed by mathematical modeling of glucose/C-peptide curves during a 240' frequently sampled OGTT and by euglycemic insulin clamp, respectively. The beta-cell responses to the rate of increase of glucose (G) (derivative or dynamic control: DC; median[IQ range]: 421[0.6-907] [pmol · m^{-2} BSA]/[mM · min^{-1}]) and to G concentration (proportional or static control, PC, presented as the insulin secretion rate at G concentrations of 5.5, 8.0, 11.0, 15.0 and 20.0 mM, respectively; 160±69, 223±122, 359±218, 572±376, 843±591 pmol · min^{-1} · m^{-2} BSA) are herein reported as measures of BF. SI is presented as the M value in the last 60' of the clamp (561[355-796] µmol · min^{-1} · m^{-2} BSA). Rs13266634 in SLC30A8 and rs5219 in KCNJ11 were genotyped in all patients.
Results: In obese patients (n=202 with BMI>=30), but not in the nonobese (p=0.40), the rs13266634 G allele of *SLC30A8* (frequency: 0.74) was associated with reduced PC (-8.5±7.7, -27.3±13.8, -60.3±24.4, -93.9±45.8, -136±74.3 at G concentrations of 5.5, 8.0, 11.0, 15.0 e 20 mM; p<0.04) and with increased levels of glucose at 2 hours during OGTT (+0.80±0.33 mmol/l, p<0.02). In nonobese patients (n=254 with BMI<30), but not in the obese (p=0.64), the rs5219 A allele of KCNJ11 (frequency: 0.39) was associated with reduced DC (-157±58; p<0.01) according to an additive model, and to both reduced PC (-6.9±10.8, -38.7±21.1, -86.8±38.3, -135±63.4, -167±97.2 at G concentrations of 5.5, 8.0, 11.0, 15.0 e 20 mM; p<0.05) and increased fasting plasma G (AA: +0.81±0.33 mmol/l; p<0.02) according to a recessive model.
Conclusion: In patients with newly diagnosed type 2 diabetes the non-synonymic variants of SLC30A8 and KCNJ11 herein investigated are associated with worse BF, with BMI (obesity) apparently playing a modifying role on this relationship. These data, if confirmed, could be useful for diagnostic, therapeutic and clinical purposes.

The presence of CAD significantly modulates the diabetes risk conferred by the TCF7L2 rs7903146 variant
S. Geller-Rhomberg[1], A. Muendlein[1,2], C.H. Saely[1,2], G. Sonderegger[1], P. Rein[1,2], T. Winder[1,2], S. Beer[1,2], A. Vonbank[1,2], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Genetic variant rs7903146 in the transcription factor 7-like 2 (TCF7L2) gene has been consistently associated with type 2 diabetes (T2DM) in several studies. It is unknown whether it confers the same amount of diabetes risk in patients with CAD as in patients who do not have CAD. We therefore aimed at investigating whether the presence of CAD modulates the association of TCF7L2 variant rs7903146 with T2DM.
Materials and methods: We therefore performed genotyping of variant rs7903146 in a large cohort of 1650 consecutive Caucasian patients undergoing coronary angiography for the evaluation of established or suspected CAD. At angiography, significant CAD was diagnosed in the presence of significant coronary stenoses with lumen narrowing of ≥50%. The association between rs7903146 and T2DM was evaluated in an additive genetic model.
Results: Variant rs7903146 was significantly associated with the presence of T2DM in the total study cohort (adjusted odds ratio (OR)=1.38 [1.15-1.65]; p<0.001). Also, diabetes duration significantly (p=0.024) increased from the CC over the CT to the TT genotype (7.7±8.6, 8.1±7.3 and 9.2±6.8 years). When patients with CAD (n=950) were analyzed separately from those without significant CAD, the association between variant rs7903146 and T2DM was strongly significant in patients with significant CAD (adjusted OR=1.59 [1.26-2.00]; p<0.001), but not in subjects who did not have significant CAD (OR=1.04 [0.77-1.40]; p=0.807). Variant rs7903146 was also significantly associated with diabetes duration in individuals with CAD (7.9±8.8 8.9±7.4 and 9.3±6.8 years for the CC, CT, and TT genotype, respectively, p=0.018), but not in patients without significant CAD (p=0.718). An interaction term CAD x rs7903146 was significant (p=0.018), indicating a significantly stronger impact of the polymorphism on T2DM risk in patients with significant CAD than in subjects without significant CAD.
Conclusion: We conclude that the presence of CAD significantly modulates the diabetes risk conferred by the TCF7L2 rs7903146 variant.

Allelic variations in the catalase gene are associated with development and progression of diabetic nephropathy in subjects with type 1 diabetes

K. Mohammedi[1,2], S. Maimaitiming[1], N. Bellili[1], N. Emery[3], K. Billariki[2,3], R. Roussel[1,2], S. Hadjadj[4], F. Fumeron[1,3], M. Marre[1,2], G. Velho[1];
[1]INSERM, Unité 695, Paris, [2]Service d'Endocrinologie-Diabétologie, AP-HP. Hôpital Bichat Claude Bernard, Paris, [3]Université Paris Diderot, Paris, [4]Service de Médecine Interne, Hôpital Universitaire de Poitiers, France.

Background and aims: Oxidative stress is involved in the pathophysiology of diabetic nephropathy (DN). The antioxidant enzyme Catalase plays a major role in the detoxification of reactive oxygen species and thus could have a protective role against DN. In this study, we tested the impact of allelic variation in the Catalase gene (CAT) on the development and progression of DN in subjects with Type 1 Diabetes Mellitus (T1DM).
Materials and methods: Twelve SNPs (table 1), giving information on ~90% of the allelic variation of the haplotypic block containing CAT gene were analyzed in 1463 subjects from three independent T1DM cohorts: the SURGENE prospective study (follow-up of 10 ± 3 years, mean ± SD), GENEDIAB and GENESIS studies. Genotypes were determined by an Assay by Design kit from Applied Biosystems. Genotype associations with DN were assessed by logistic regression analyses. Associations with DN severity were assessed by ordinal logistic regression analyses, with stages of DN coded as ordinal polytomic dependent variables: absence (1), microalbuminuria (2), macroalbuminuria (3), reduced renal function (4) and end stage renal failure (5).
Results: In the SURGENE cohort, the rs7947841 variant was associated with DN both at baseline (Odds Ratio 8.60, 95% C.I. 1.83 - 40.32, p=0.005) and at follow-(Odds Ratio 4.34, 95% C.I. 1.29 - 14.78, p=0.01). The variant was also associated with the severity of DN, both at baseline (p=0.005) and at follow-up (p=0.001). In GENEDIAB cohort, five SNPs were associated with DN (Table 1). These SNPs were also associated with the severity of DN severity (p=0.009, p=0.06, p=0.02, p=0.006 and p=0.006, respectively) and with microalbuminuria (p=0.03, p=0.05, p=0.04, p=0.01 and p=0.003, respectively). We have also observed associations of these variants with arterial hypertension.
Conclusion: We have observed associations of CAT allelic variations with diabetic nephropathy, its severity and with intermediate phenotypes in subjects with T1DM. We are currently performing haplotypic studies in the 3 cohorts and analysis of 6 years follow-up data of GENESIS and GENEDIAB cohorts.

Table 1: GENEDIAB study: Association of CAT polymorphisms with diabetic nephropathy

SNP	Diabetic nephropathy at baseline	
	Odds ratio (95% IC)	p*
rs2266630	1.17 (0.41 - 3.66)	0.76
rs1001179	2.84 (1.24 - 6.79)	0.01
rs11032699	1.23 (0.63 - 2.42)	0.54
rs12272630	0.18 (0.04 - 0.77)	0.02
rs2300182	0.77 (0.33 - 1.84)	0.56
rs11032703	1.22 (0.40 - 3.87)	0.73
rs2300181	0.65 (0.32 - 1.33)	0.24
rs10488736	0.44 (0.22 - 0.88)	0.02
rs2420388	1.00 (0.49 - 2.08)	0.99
rs566979	0.44 (0.23- 0.86)	0.01
rs7947841	1.87 (0.55 - 6.73)	0.32
rs499406	2.14 (1.07 - 4.32)	0.03

*Adjusted for sex, age, duration of diabetes, HbA1c and ACE inhibitors

Does genetic variability in the fructosamine-3-kinase play a role in the progression of diabetic nephropathy, morbidity and mortality of diabetics?

L. Pácal[1], V. Tanhäuserová[1], J. Svojanovský[2], D. Krusová[2], S. Štěpánková[3], J. Olšovský[2], J. Bělobrádková[3], J. Řehořová[3], J. Smržová[3], K. Kaňková[1];
[1]Department of Pathophysiology, Faculty of Medicine, Masaryk University, [2]Department of Internal Medicine, St. Anne's Faculty Hospital, [3]Department of Gastroenterology, Faculty Hospital Brno-Bohunice, Brno, Czech Republic.

Background and aims: Fructosamines are products of non-enzymatic glycation formed in accelerated rate during hyperglycemia. As precursors of advanced glycation end-products (AGEs) fructosamines supposedly contribute to the development of glucotoxic injury. Mechanism of enzymatic deglycation of proteins *in vivo* by fructosamine-3-kinase (FN3K) was described recently. FN3K is a ubiquitous intracellular enzyme that phosphorylates fructosamines resulting in unstable fructosamine-3-phosphate, which subsequently spontaneously decomposes to inorganic phosphate, 3-deoxyglucosone and the unmodified amine. Recently, the -385A/G (rs3859206) and 900C/G (rs1056534) single nucleotide polymorphisms (SNPs) in the FN3K gene were found to have potential functional impact - association with FN3K enzyme activity in erythrocytes (genotypes -385AA and 900GG associated with lowest enzymatic activity). Fructosamine pathway may therefore represent either potentially protective metabolic process in hyperglycemia since degradation of fructosamines prevents formation of Lys-based AGEs or quite the reverse - harmful process - by formation of 3-deoxyglucosone as a potent mobile Arg-directed glycating agent. The aim was to study relationship between polymorphisms in FN3K gene, progression of diabetic nephropathy (DN) and cardiovascular morbidity and mortality of diabetics.
Materials and methods: Study comprised a total of 420 T1DM or T2DM subject with variable stage of DN (i.e. normoalbuminuria, microalbuminuria, proteinuria or ESRD) prospectively followed for 45 [21 - 63] months (median [IQR]). Following end-points were considered: [1] renal (progression of DN by stage or reaching the ESRD), [2] major cardiovascular event (MCVE: non-fatal myocardial infarction or stroke, limb amputation), [3] cardiovascular mortality (CVM: fatal myocardial infarction, stroke or sudden death) and [4] all-cause mortality (AM). SNPs were genotyped by PCR with subsequent RFLP.
Results: Progression of DN was reached in 16.5% of subjects, MCVE in 15.6%, CVM in 9.9% and ACM in 19.3%. Allele and genotype frequencies did not differ between DN stage groups (chi-square test). Using Kaplan-Meier time-to-event analysis significant effects were ascertained for the carrier state of the -385AA and 900GG genotype combinations and progression of DN, MCVE and CVM (all P<0.05, log-rank test). In all cases, group defined by the presence of at least one "low-activity" allele in both positions (i. e. -385AA or AG combined with 900GG or GC) were associated with significantly longer median of time to DN progression, MCVE and CVM.
Conclusion: Interindividual variability in FN3K enzyme activity represents potentially significant genetic risk factor for the progression of DN and cardiovascular morbidity and mortality of diabetics. Based on our results, we can't identify high FN3K deglycating activity as a protective factor, on the contrary higher rate of 3-deoxyglucosone formation may counterbalance putative protection by providing substrate for Arg-directed glycation and AGE formation.

***PPAR-γ2* P12A polymorphism and albuminuria in patients with type 2 diabetes**

S. De Cosmo[1], S. Prudente[2], O. Lamacchia[3], D. Camarchio[3], M. Cignarelli[3], M. Copetti[4], V. Trischitta[5];
[1]Unit of Endocrinology, Scientific Institute "Casa Sollievo della Sofferenza", SGR, Foggia, [2]CSS-Mendel Institute, Rome, [3]Department of Medical Sciences, Unit of Endocrinology, Foggia, [4]Scientific Institute "Casa Sollievo della Sofferenza", SGR, Foggia, [5]Scientific Institute Casa Sollievo della Sofferenza and University of Rome, SGR, Foggia and Rome, Italy.

Background and aims: Insulin resistance (IR) is believed to be pathogenic for albuminuria in patients with T2D. The *PPAR-γ2* P12A polymorphism has been consistently associated with IR and T2D with the A12 variant playing a protective role. The association of this variant with a reduced risk of albu-

minuria in T2D has been controversial. The aim of this study was to investigate the relationship between PPAR-γ2 P12A polymorphism and albuminuria in patients with T2D.
Materials and methods: To get deeper insights about this issue, we first tested the association between the A12 variant and albuminuria in two new case-control studies in patients with T2D from Italy, and then performed a meta-analysis of all studies available to date. The first study comprised 261 cases (162 male/99 female; age, 63.2±10.0 yrs) and 580 controls (264 male/316 female; age, 61.6±9.5 yrs) recruited at Scientific Institute CSS in San Giovanni Rotondo. The second study comprised 254 cases (131male/123 female; age, 63.9±12.2 yrs) and 369 controls (170 male/199 female; age, 62.2±12 yrs) recruited at University Hospital of Foggia. In these 2 studies, albuminuria was defined if ACR was ≥2.5 in men and 3.5 mg/mmol in women. Pro12Ala polymorphism was genotyped by TaqMan-based assay in genomic DNA. The 8 studies we meta-analyzed comprised 2144 cases and 3706 controls. In four studies albuminuria was determined by albumin excretion rate (AER) and in four by albumin concentration in a single spot (i.e. urine albumin/creatinine ratio in 3 studies and urinary albumin concentration in one study).
Results: The overall OR (95% CI) for association between A12 and albuminuria was 0.67 (0.49-0.91), with values of individual studies ranging from 0.29 to 1.13. A significant heterogeneity of the genetic effect was observed (Cochran's *Q* test p=0.017). Approximately one third of it (36.4%) was explained by the different method of urine collection and albuminuria definition utilized across the studies. Most of the protective effect of the A12 variant was observed in the 4 studies using AER rather than in those using albumin concentration in a single spot (OR, 95% CI: 0.52, 0.34-0.79, p=0.0024 and 0.84, 0.58-1.21, p=0.35, respectively).
Conclusion: The present meta-analysis shows that the PPARγ2 Ala12 variant is significantly associated with a reduced risk of albuminuria among patients with T2D. This association is particularly evident among studies where the ascertainment of case-control status was obtained by measurement of albumin excretion rate.

319

INPPL1 gene is associated with the metabolic syndrome but not with diabetic nephropathy in patients with type 1 diabetes

M.E. Hyvönen[1,2], C. Forsblom[3,4], P. Ihalmo[3], J. Söderlund[3], N. Sandholm[3], M. Parkkonen[3], L. Thorn[3,4], S. Lehtonen[1], P.-H. Groop[3,4], FinnDiane Study Group;
[1]Department of Pathology, University of Helsinki, [2]Hospital for Children and Adolescents, [3]Folkhälsan Institute of Genetics, University of Helsinki, [4]Department of Medicine, Helsinki University Central Hospital, Finland.

Background and aims: The metabolic syndrome has been shown to be a frequent phenomenon in patients with type 1 diabetes and to associate with diabetic nephropathy. *INPPL1* gene encodes lipid phosphatase SHIP2, a negative regulator of PI3-kinase mediated insulin signaling. Polymorphisms in *INPPL1* gene have been found to associate with components of the metabolic syndrome in British and Japanese cohorts. The aim of this study was to investigate if single nucleotide polymorphisms (SNPs) in *INPPL1* are associated with the metabolic syndrome or diabetic nephropathy in Finnish patients with type 1 diabetes.
Materials and methods: We selected 2520 patients participating in the FinnDiane study for this cross-sectional study. The metabolic syndrome was defined according to the most recent criteria (joint statement 2009), and patients were divided into controls without the metabolic syndrome (n=1010) and cases with the metabolic syndrome (n=1475), as well as into four groups based upon their albumin excretion rate: normoalbuminuria (n=1256), microalbuminuria (n=442), macroalbuminuria (n=553) and end stage renal disease (n=266). Nine SNPs were selected for genotyping from the HapMap database (CEPH, r^2>0.8) for *INPPL1* gene plus/minus 20 kbs. Genotyping was performed with ABI Prism 7900 Sequence Detection System based on TaqMan chemistry. The associations between the SNPs and outcome variables were analysed with the Chi-squared test.
Results: Two *INPPL1* SNPs, rs2276047 (in an intron) and rs2276048 (silent mutation), were found to associate with the metabolic syndrome in males, with p-values 0.018 and 0.001, respectively. When both genders were included, the association was not significant. No association between the genotyped SNPs and various degrees of nephropathy was observed.
Conclusion: *INPPL1* gene variants may contribute to susceptibility to the metabolic syndrome, however, not to diabetic nephropathy in patients with type 1 diabetes.

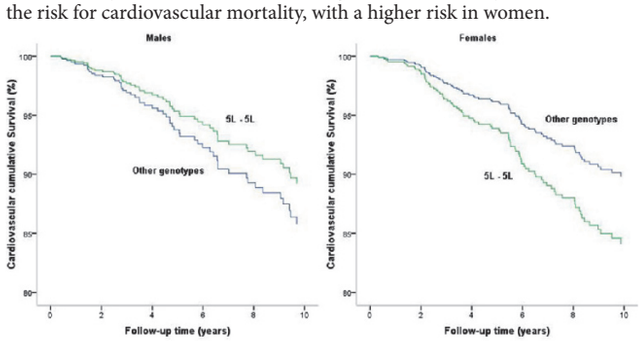
CNDP1 gene polymorphism predicts cardiovascular mortality in female patients with type 2 diabetes (ZODIAC 22)

A. Alkhalaf[1,2], K.J.J. van Hateren[2], G.W.D. Landman[2,3], S.J.L. Bakker[1], G.J. Navis[1], N. Kleefstra[2,4], H.J.G. Bilo[1,2];
[1]Internal Medicine, University Medical Center Groningen, [2]Diabetes Centre, Isala Clinics, Zwolle, [3]Internal Medicine, Isala Clinics, Zwolle, [4]Langerhans Medical Research Group, Zwolle, Netherlands.

Background and aims: Carnosine has been shown to be protective against oxidative stress and endothelial damage. Homozygosity for 5-leucine repeat (5L-5L) in the carnosinase gene (CNDP1) has recently been found to be associated with diabetic nephropathy in cross-sectional studies, mainly in women with type 2 diabetes. Longitudinal data on survival are, however, not yet available. We prospectively investigated whether allelic variation in CNDP1 predicts (cardiovascular) mortality in patients with type 2 diabetes and to what extent this is modified by sex.
Materials and methods: This study is part of the ZODIAC study, a prospective observational study in primary care patients with type 2 diabetes. Leucine repeats in CNDP1 were assessed by fluorescent DNA analysis. In 2009, data on mortality were collected. A Cox proportional hazard model was used to compare 5L-5L with other allelic variations, after adjustment for potential confounders, including age, body mass index, duration of diabetes, macrovascular complications, systolic blood pressure, HbA_{1c}, total cholesterol to HDL-cholesterol ratio, plasma creatinine, and urine albumin excretion. Furthermore, CNDP1 and sex were entered as an interaction term.
Results: 872 patients [age 68.1 ± 11.2 years, 366 (42%) males] were included. At baseline, median diabetes duration was 5 (interquartile range (IQ) 2-11) years, mean HbA_{1c} 56 ± 12 mmol/mol, plasma creatinine 91 (IQ 82-104) μmol/L, and urinary albumin creatinine ratio 1.94 (IQ 0.95-6.18) mg/mmol. 5L-5L was found in 331 patients (38%; this was for men 39% and for women 37%). After 9.5 (IQ 5.9-10.3) years of follow-up, 136 (41%) patients with 5L-5L had died, with 55 deaths (17%) attributable to cardiovascular causes. In patients with other allelic variants, these numbers were 205 (38%) and 81 (15%), respectively. Adjusted hazards ratios (HR) for all-cause mortality and cardiovascular mortality in 5L-5L versus other allelic variants were 1.08 (95%CI 0.87-1.35) and 1.12 (95%CI 0.79-1.60), respectively. There was a significant interaction between allelic variation in CNDP1 and sex for prediction of cardiovascular mortality (*P*=0.02), but not for all-cause mortality (*P*=0.69). After stratification for sex, adjusted HRs of 5L-5L for cardiovascular mortality were 0.74 (95%CI 0.42-1.32, *P*=0.31) in males and 1.61 (95%CI 1.02-2.55, *P*=0.04) in females.
Conclusion: In this prospective study on allelic variation in CNDP1 in patients with type 2 diabetes, 5L-5L was gender-dependently associated with the risk for cardiovascular mortality, with a higher risk in women.



Adjusted cardiovascular survival curves in male and female patients with type 2 diabetes according to their CNDP1 genotype

321

Two common variants on 9p21 affect mortality risk in type 2 diabetes patients (ZODIAC-15)

G.W.D. Landman[1], J.V. van Vliet-Ostaptchouk[2], N. Kleefstra[1,3], K.J.J. van Hateren[1], I. Drion[1], K.H. Groenier[4], R.O.B. Gans[5], C. Wijmenga[6], M.H. Hofker[2], H.J.G. Bilo[7,5];
[1]Diabetes Centre, Isala Clinics, Zwolle, [2]Molecular Genetics, Department of Pathology and Medical Biology, University Medical Centre Groningen and University of Groningen, [3]Langerhans, Medical Research Group, Zwolle, [4]General Practice, University Medical Centre Groningen, [5]Internal Medicine, University Medical Centre Groningen, [6]Department of Genetics, University Medical Centre Groningen and University of Groningen, [7]Diabetes Centre, Internal Medicine, Isala Clinics, Zwolle, Netherlands.

Background and aims: Recent genome wide association (GWA) studies identified two single nucleotide polymorphisms (SNP), rs10811661 and rs10757278 in the same region on the 9p21 chromosome to be consistently and independently associated with the risk of developing type 2 diabetes (T2DM) and cardiovascular disease, respectively.
We examined the SNPs in relation to the risk of total and cardiovascular mortality in a population based cohort of T2DM patients.
Materials and methods: The ZODIAC study is a prospective cohort study of T2DM patients treated in primary care in the Netherlands. Rs10811661 and rs10757278 were genotyped in 914 subjects from the ZODIAC study and 920 healthy Dutch controls. Associations of the SNPs with mortality were assessed by use of Cox proportional hazard analyses.
Results: After a median follow-up of 9.5 years 358 out of 914 patients had died. The adjusted Hazard Ratio's (HR) for total mortality for patients homozygote and heterozygote for the wild type allele of rs10811661 was 1.34 (95% CI 1.06-1.69, p=0.01) compared to individuals homozygous for the risk allele. For rs10757278 total mortality was lower among patients heterozygous and homozygous for the wild-type allele than in homozygous carriers for the risk allele (HR 0.64 (95%CI 0.43-0.95), p=0.03, and HR 0.73 (95%CI 0.48-1.11), p=0.14, respectively). This effect was more pronounced in the lower tertile of HbA1c: the adjusted HR for patients heterozygous and homozygous for wild-type allele of rs10757278 was 0.48 (95%CI 0.28-0.83, p=0.01) and 0.48 (95%CI 0.27-0.85, p=0.01), respectively, compared with the patients homozygous for the risk allele.
Conclusion: This prospective study shows a significant association between two common SNPs on 9p21 and mortality in type 2 diabetes patients.

322

Genome wide association analysis for free fatty acid levels in DGI

I.A. Stojkovic[1], C. Saloranta[2], P. Almgren[3], V. Lyssenko[3], E. Laurila[3], M. Svensson[1], A. Sharma[1], B. Isomaa[4], L. Groop[3], M.O. Melander[1];
[1]Diabetes, Cardiovascular Disease and Genetic Epidemiology, Lund University, Malmö, Sweden, [2]Department of Medicine, Helsinki University Hospital, Finland, [3]Diabetes and Endocrinology, Lund University, Malmö, Sweden, [4]Department of Medicine, Folkhälsan Research Center, Helsinki, Finland.

Background and aims: Recent genome-wide association studies (GWAS) have identified a number of common single nucleotide polymorphisms (SNPs) that contribute to multifactorial human phenotypes. Free fatty acids (FFAs) serve as physiologically important energy substrates and their release from adipose tissue is regulated by the energy demands of the body. FFAs are increased in obese patients and T2D and cause insulin resistance in all major insulin target organs. Although FFA levels have a heritability of 50-60%, very little is known about contributing genetic factors. The aim of this study is to identify genetic factors regulating FFA levels using a GWAS approach.
Materials and methods: In total 1094 non-diabetic unrelated individuals (49% males, age 59±11 years, BMI 27±4 kg/m^2) from the Diabetes Genetics Initiative (DGI) GWAS of 500K were included in the analyses. FFA-levels were determined using Half-micro and Micro 96-plate methods with two different kits NEFA HR (2) and NEFA C (Waco), after an overnight fast (FFA0) and after an OGTT (FFA120) and a dFFA was calculated reflecting insulin suppression (FFA0-FFA120). FFA-levels of the 1094 individuals were FFA0 655±235 μmol/l, FFA120 221±114 μmol/l and dFFA 432±221. Linear regression analyses were performed in plink with age, sex, fasting insulin, BMI and region or age, sex and region as covariates. Replication analyses are performed among 2845 participants of the Botnia Prevalence, Prediction and Prevention of Diabetes study (Botnia-PPP: 47% males, age 48±15 years, BMI 27±4 kg/m^2, FFA0 593±246 μmol/l, FFA120 159±80 μmol/l and dFFA 431±229).
Results: In DGI, the lowest p-values for FFA0, FFA120 and dFFA were found in or near *TUB*, *UBE2NL/SPANXN2* and *c4orf32/TIFA* loci on chromosomes 11, 23 and 4 (p= 1x10^{-6}, p=1x10^{-5} and p=4x10^{-6}, respectively). In total 24, 15 and 29 SNPs provided p-values of less than 1x10^{-4} for FFA0, FFA120 and dFFA, respectively. 14 loci associated with both FFA120 and dFFA with p<1x10^{-4}. All SNPs with p<1x10^{-4} in DGI were chosen for replication in Botnia-PPP. Similar to DGI, the *TUB* SNP associated with significantly lower dFFA in PPP (p=0.0005) while association with FFA0 did not reach statistical significance (p=0.065). These results were similar with and without adjustment for fasting insulin and BMI.
Conclusion: A GWAS for FFA identified 64 loci with p<1x10^{-4} and replication genotyping of these loci is ongoing. Our results so far provide evidence for involvement of *TUB* gene in regulation of FFA levels in man. *TUB* codes for the human homolog of a gene that causes maturity onset obesity and insulin resistance in *tubby* mice.

323

Interpretation of genome wide association data for lipoprotein traits using systems biology approach

A. Sharma[1], N. Gulbahce[2], S. Lang[1], C. Ladenvall[1], S. Kathiresan[3], M. Orho-Melander[1], A.-L. Barabasi[2];
[1]Diabetes and Cardiovascular Diseases, Genetic Epidemiology unit, Lund University, University Hospital Malmö, Sweden, [2]Department of Physics, Center for Complex Network Research, Boston, [3]Center for Human Genetic Research and Cardiovascular Research Center, General Hospital, Harvard Medical School, Boston, USA.

Background and aims: Genome wide association studies (GWAS) with large meta-analyses have identified a number of new loci contributing to multifactorial diseases. Hereby we assumed that by analysis of interaction networks of GWAS genes with SNPs providing P <5x10^{-8} (seed genes) in meta-analysis data of Global Lipids Genetics Consortium (GLGC) including > 100,000 individuals it could be possible to reveal novel candidate genes and pinpoint important pathways for lipid and lipoprotein traits. By integrating GLGC meta-analysis data with Molecular networks (expression, transcriptional, proteomic and metabolic interaction networks) as well as with phenotypic disease network (comorbidity network), we wish to gain new biological insights for better understanding of lipoprotein metabolism.
Materials and methods: GLGC meta-analysis data of ~ 2.6 million genotyped or imputed SNPs for four lipid/lipoprotein traits i.e. total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and triglycerides (TG) was analyzed. After correcting for linkage disequilibrium, SNPs were assigned to genes on the basis of being located within 20kb region of first and last exon. We defined a seed genes data set (association p-value <5x10^{-8}) of 112 genes for HDL-C, 117 for LDL-C, 158 for TC and 115 for TG. Interaction information gleaned from the first order neighbours and second order neighbours were used in further analysis. We then approached to identify additional candidate genes by studying clusters of seed genes using Molecular Triangulation (MT) algorithm. In the next step we only selected genes that were co-expressed with the seed genes using 79 human tissues expression data. Further, the GLGC meta-analysis p-values of seed genes were superimposed on the interaction networks to identify the sub-networks and additional 100 random control networks were generated. For weighing the identified sub-networks for comorbidity we utilized the large scale US Medicare database of comorbidity patterns of 13 millions patients.
Results: By MT algorithm we identified 223, 172, 140 and 243 additional candidate genes for HDL-C, LDL-C, TG and TC with significance of real scores of P=5.4x10^{-5}, P=4.7x10^{-5}, P=4.4x10^{-5} and P=6.5x10^{-5}, respectively. Receiver operating characteristic (ROC) curve showed accuracy of 93% and sensitivity of 64% for MT algorithm with the seed genes. After priorization of those additional candidate genes that co-expressed with seed genes and were present in the sub-networks having highest comorbidity values we were left with 39, 19, 27 and 20 genes for HDL-C, LDL-C, TG and TC. Of these genes, lowest p-values in GLGC meta-analysis data were for HDL-C in *INSR* (P=2x10^{-5}) and *ASCC2* (P=0.0005), for LDL-C in *SH3GL2* (P=0.0001) and *NDUFA4L2* (P=0.0003), for TG in *GCK* (P=3.7x10^{-5}) and *RAF1* (P=8.6x10^{-5}) and for TC in *SH3GL2* (P=0.0002) and *GOLM1* (P=0.004).
Conclusion: Combining large GWAS meta-analysis data with systems biology approaches and comorbidity data identified new candidate genes for lipoprotein traits and addresses the importance of network based genetic analyses in the future.

Association of FTO gene variation with fat oxidation in women with polycystic ovary syndrome

I. Kowalska[1], A. Adamska[1], M.T. Malecki[2], M. Karczewska-Kupczewska[1], A. Nikolajuk[1], M. Szopa[2], A. Lebkowska[1], M. Górska[1], M. Straczkowski[1]; [1]Endocrinology, Diabetology and Internal Medicine, Medical University, Bialystok, [2]Department of Metabolic Diseases, Jagiellonian University, Medical College, Krakow, Poland.

Background and aims: Polycystic ovary syndrome (PCOS) is heterogeneous disorder, where insulin resistance might be involved in the development of endocrine and metabolic abnormalities. It was recently shown that the *FTO* gene modifies weight, fat mass and insulin sensitivity in women with polycystic ovary syndrome, where its role might be larger than in other phenotypes. The aim of the present study was to estimate the effect of *FTO* variation on glucose and lipid oxidation in PCOS women.
Materials and methods: The study group consisted of 68 women with PCOS and 25 healthy, normally menstruating women. Clinical examination, anthropometric measurements, euglycemic hyperinsulinemic clamp and the measurements of serum sex hormones were performed. Glucose and lipid oxidation was evaluated with indirect calorimetry in the baseline state and during the last 30 minutes of the clamp. The *FTO* rs9939609 polymorphism was genotyped using the restriction fragment length polymorphism method.
Results: There was no difference in glucose and lipid oxidation between PCOS and control women. TT homozygotes had higher baseline fat oxidation in comparison to the carriers of A allele (p=0.019) in the entire study population. We found similar differences when PCOS women were analyzed separately (p=0.018). We did not observe the effect of *FTO* gene variation on insulin-stimulated lipid oxidation and either baseline or insulin-stimulated glucose oxidation.
Conclusion: Our data show that *FTO* gene variation might influence baseline lipid oxidation in PCOS patients. This might be one of potential mechanism explaining the impact of the *FTO* gene on body weight.

Impact of the I148M mutation in PNPLA3 (adiponutrin) on weight loss-induced decrease in liver fat

K. Sevastianova[1], A. Kotronen[1], A. Gastaldelli[2], A. Hakkarainen[3], N. Lundbom[3], E. Ferrannini[2], A. Rissanen[4], H. Yki-Järvinen[1]; [1]Department of Internal Medicine, Helsinki University Central Hospital, Finland, [2]Department of Internal Medicine, University of Pisa School of Medicine, Italy, [3]Department of Radiology, Helsinki University Central Hospital, [4]Department of Psychiatry, Obesity Research Unit, Helsinki University Central Hospital, Finland.

Background and aims: The rs738409 C>G single nucleotide polymorphism (SNP) in the patatin-like phospholipase domain-containing 3 (PNPLA3; adiponutrin) gene leads to a missense mutation (I148M) in PNPLA3. Carriers of the GG genotype (prevalence ~5%) have a marked 60% increase in liver fat. *In vitro*, adiponutrin has been associated with both transacylase and lipase activities. We explored whether the I148M variant in the adiponutrin gene influences weight loss -induced decrease in liver fat in humans.
Materials and methods: We recruited 17 subjects of whom 8 had the GG genotype and 9 the CC genotype. We matched the groups with respect to age (48 ± 4 vs. 53 ± 4 yrs, GG vs. CC, NS), BMI (29.2 ± 2.1 vs. 31.5 ± 1.9 kg/m^2, NS) and liver fat (10.2 ± 1.8 vs. 13.2 ± 1.8 %, NS). The subjects were placed on a hypocaloric (1000 kcal deficit/ day) low-carbohydrate (<20 g/ day) diet for six days. Liver fat was measured by proton magnetic resonance spectroscopy before and after the intervention. Whole-body insulin sensitivity was measured by the euglycemic insulin (0.4 mU * kg^{-1} * min^{-1}) clamp technique.
Results: Weight loss was similar in both groups (-3.7 ± 3.5 vs. -3.3 ± 0.3 kg, GG vs. CC, NS). Liver fat decreased by 45 % in the GG and by 20 % in the CC group (p=0.046). Whole-body insulin sensitivity increased significantly in the GG group from 0.90 ± 0.18 to 1.33 ± 0.25 mg * kg^{-1} * min^{-1} (p=0.04) and remained unchanged in the CC group (0.62 ± 0.10 vs. 0.68 ± 0.11 mg * kg^{-1} * min^{-1}, p=0.58). No significant differences between changes in fasting concentrations of triglycerides, glucose or insulin were observed.
Conclusion: These data suggest that the I148M mutation facilitates weight loss -induced mobilization of intrahepatocellular triglyceride *in vivo* in humans.

PS 8 Epidemiology and genetics of adiposity

Three year-follow-up incidence of cardio-metabolic alterations in a metabolically normal population

Z. Pataky, E. Bobbioni-Harsch, V. Makoundou, A. Golay; WHO Collaborating Centre, University Hospitals of Geneva, Switzerland.

Background and aims: It has been claimed that obese subjects with normal metabolic profile are not at increased risk for cardio-metabolic diseases, as compared to normal body weight. The aim was to compare the 3-year evolution of cardio-metabolic parameters in normal body weight (NBW) and obese (OB) healthy subjects, free from MS and with a normal glucose tolerance at baseline.
Materials and methods: We investigated a sub-group of the RISC study (Relationship between Insulin Sensitivity and Cardiovascular Disease) participants (NBW=288 and OB=141) free from metabolic syndrome (MS, according to IDF criteria) and with a normal glucose tolerance at baseline. In these subjects, fasting insulin was measured and insulin sensitivity was assessed by euglycaemic hyperinsulinaemic clamp. Based on quartiles established in NBW, both NBW and OB subjects were classified as normo-insulinaemic or hyper-insulinemic and insulin sensitive or insulin resistant. Metabolic normality was defined as the presence of normal levels of both fasting insulin and insulin sensitivity. Three years later, the cardio-metabolic parameters suggested by the IDF to define MS as well as glucose tolerance were re-measured.
Results: At 3 years, the incidence of MS was 6.6% in NBW and 21.3% in OB (p<0.0001), the incidence of impaired fasting glucose was 7.6% vs 20.6% (p<0.0001) and of impaired glucose tolerance 3.8% vs 10.6% (p=0.005), in NBW and in OB respectively. Hypertension occurred in 6.3% of NBW vs 14.9% in OB (p=0.003). In the overall population, both BMI at baseline and BMI modifications along the 3-year period were predictors for MS (OR=1.12, p=0.04 and OR=1.44, p=0.01, respectively), whereas BMI at baseline was predictor of impaired fasting glucose (OR=1.20, p=0.001). BMI evolution predicted impaired glucose tolerance (OR=1.44, p=0.02) and hypertension (OR=1.47, p=0.04).
Conclusion: Even when metabolically normal, OB subjects show an increased risk for MS, pre-diabetes and hypertension. Therefore, they need a closer surveillance.

Gestational diabetes is not associated with adiposity measurements in 18 months offspring: the mother child rhea cohort in Crete, Greece

L. Chatzi[1], E. Papadopoulou[1], M. Vafeiadi[1], K. Mathianaki[1], A. Pappas[2], A. Koutis[1], M. Kogevinas[3,4]; [1]Department of Social Medicine, Heraklion, [2]Diabetic Clinic, Venizelio Hospital, Heraklion, Greece, [3]Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain, [4]National School of Public Health, Athens, Greece.

Background and aims: Studies of developmental origins of health and disease have put focus on the possible role of intrauterine exposure to hyperglycemia in the pathogenesis of obesity and cardiovascular disease in offspring. Although gestational diabetes is a strong risk factor for obesity in the offspring, the age at which this association becomes apparent is unknown. The purpose of this study was to examine the relation of gestational diabetes with measures of adiposity in early childhood.
Materials and methods: The mother-child "Rhea"study in Crete is a prospective cohort examining pregnant women (Greek and immigrants) residents at the prefecture of Heraklion that became pregnant during one year starting in February 2007 and initiated prenatal care before 15 weeks of gestation (mean: 12 weeks). Six hundred and thirty five pregnant women and their children, were included in the analysis. Pregnant women were screened for gestational diabetes (GDM) between 24 and 28 weeks of gestation, and GDM was defined by the criteria proposed by Carpenter and Coustan. Weight, height, abdominal circumference, and thickness of triceps, subscapular, suprailiac, and subscapular were measured in 635 children at 18 months of age (59 offspring of mothers with gestational diabetes). Multivariable linear and logistic regression models were used to estimate the effect of GDM on the risk of adiposity in early childhood after adjusting for offspring sex, age, maternal education, and parity.

Results: Offspring of mothers with gestational diabetes did not differ significantly in BMI (beta coefficient: -0.20, 95% Confidence Intervals: -0.83-0.44), abdominal circumference (beta coefficient: 0.30, 95% Confidence Intervals: -0.65-1.25), or body fat percentage (beta coefficient: -0.27, 95% Confidence Intervals: -1.59-1.05) compared with offspring of non-diabetic mothers after adjustment for offspring sex, age, maternal education, and parity. Similarly, adiposity rates (BMI≥85th percentile-Odds ratio: 0.96; 95% Confidence Intervals:0.44-1.55 , abdominal circumference≥85th percentile-Odds ratio: 1.29; 95% Confidence Intervals: 0.59-2.84, sum of skin folds >85th percentile-Odds ratio: 1.14; 95% Confidence Intervals: 0.20-1.26, and percent body fat >85th percentile-Odds ratio: 0.95; 95% Confidence Intervals: 0.36-2.55) did not differ significantly between the two groups.
Conclusion: The study found no association between gestational diabetes and obesity in early childhood. These findings are consistent with the few other studies with adiposity measurements in early childhood. Further follow up of this cohort will allow determining if gestational diabetes has, an effect on obesity and cardiovascular risk in later childhood.

Body mass index and fasting glucose levels in a large cohort of patients assigned to age decades between <20 and >80 years - relationship with cardiovascular events and medication

A. Dzien[1], C. Dzien-Bischinger[1], E. Theurl[2], H. Winner[3], M. Lechleitner[4];
[1]Internal Medicine, Medical Center Hentschelhof, Innsbruck, [2]Public Economics, University of Innsbruck, [3]Economics and Social Sciences, University of Salzburg, [4]Internal Medicine, Hospital Hochzirl, Zirl, Austria.

Background and aims: There is an ongoing debate about the relationship between obesity and morbidity in the elderly and the clinical relevance of overweight in older patients. The main purpose of our study was to investigate whether a higher BMI is associated with an increase in fasting glucose levels and cardiovascular morbidity in all age groups.
Subjects and methods: We performed a retrospective evaluation of clinical data from 5374 patients who visited a medical outdoor center for diagnostic and/or therapeutic interventions in the period from January 1995 to September 2009. Patients were assigned to eight age groups of one decade from <20 years to ≥80 years and results were analyzed with respect to the presence or absence of cardiovascular events and need for medication.
Results: The Body Mass Index (BMI) revealed a hump-shaped pattern, with a peak in the age group 60-69. In all age groups, there was a significant difference in the BMI in patients with and without a cardiovascular event. BMI and the percentage of body fat were higher in all patients with cardiovascular events. The fasting glucose values increased continuously in the patients without events from 85.7±15.9 mg/dL in the age group <20 to 115.6±40.4 mg/dL in patients ≥80 years. In patients with events fasting glucose values increased up to 134.8±61.6 mg/dL in the age group 40-49, and, probably because therapeutical interventions were begun at that point, no further increase could be observed with increasing age. The analysis of patients with and without a need for medication demonstrated that patients with a need for medication revealed higher fasting glucose levels in the age groups between <20 and 60-69 years. Fasting glucose values showed a continuous increase with increasing age with the highest values in the age group 70-79 in patients without medication (112.2±30.4 mg/dL) and in the age group ≥80 in patients with medication (115.1±41.6 mg/dL).
Conclusion: Our study supports the hypothesis that overweight is a risk factor not only for younger and middle-aged, but also for active elderly patients. Fasting glucose levels revealed a continuous increase up to the oldest age groups. Preventive strategies for type 2 diabetes should thus be offered for all age groups.

329

Comparison of visceral adiposity and liver fat in 4277 individuals from an international cohort of patients classified according to their glucose tolerance status: the INSPIRE ME IAA Study

J.-P. Després[1], S.M. Haffner[2], B.J. Balkau[3], R. Ross[4], N. Alméras[1], INSPIRE ME IAA investigators;
[1]Quebec Heart and Lung Institute, Quebec, Canada, [2]Baylor College of Medicine, Houston, USA, [3]INSERM Unit 1018, Villejuif, France, [4]Queen's University, Kingston, Canada.

Background and aims: Excess visceral adiposity and liver fat are well known correlates of metabolic abnormalities increasing the risk of type 2 diabetes (T2D) and cardiovascular disease. The first aim of the INSPIRE ME IAA study was to determine the relationships between visceral adiposity and liver fat measured by computed tomography (CT), related cardiometabolic risk markers and history of ischemic cardiovascular events and T2D.
Materials and methods: The INSPIRE ME IAA study (INternational Study of Prediction of Intra-abdominal adiposity and its RElationships with cardioMEtabolic risk/Intra-Abdominal Adiposity) is an international observational prospective study with a planned 3-yr follow up conducted in 29 countries and involving 297 physicians. Physicians were either 1- hospital based primary care physicians and internists, 2- cardiologists or 3- endocrinologists/diabetologists with approximately 1/3 of each clinical practice group represented. Of the 4505 patients included in the study, 4277 had data available for the present analyses. Male outpatients were aged 40-70 years whereas female outpatients were aged 45-70 years. At baseline, demographic and clinical data were obtained as well as a cardiometabolic profile which included a 75 g oral glucose tolerance test. Visceral adiposity and liver fat were measured by CT and all images were read centrally by a core imaging laboratory. The present analyses focus on the comparison of visceral adiposity/liver fat across subgroups of patients defined according to their glucose tolerance status: 1- normal (NGT), 2- impaired fasting glucose (IFG) or impaired glucose tolerance (IGT), 3- controlled T2D (HbA1c<7%), 4- poorly controlled T2D (HbA1c≥7%). All comparisons across the 4 groups were adjusted for age, region and clinical practice group.
Results: Across the 4 groups with differing glucose control, there was a clear gradient for waist circumference with the lowest values found in NGT subjects and the highest in poorly controlled T2D patients (p<0.001). Accordingly, there was also a positive gradient for fasting triglyceride levels and a negative gradient for HDL-cholesterol, the lowest values being found in patients with poorly controlled T2D (p<0.005). There was also a progressive increase in visceral adiposity measured by CT from the NGT subjects to the poorly controlled patients with T2D (p<0.001). Mean attenuation value of the liver (used as an index of liver fat) also showed significant group differences (p<0.001). In men and women, significant correlations were observed between visceral adiposity and the CT-derived index of liver fat (r=-0.39 in men and r=-0.47 women, p<0.001).
Conclusion: INSPIRE ME IAA is the largest international study on visceral adiposity/liver fat and cardiometabolic risk profile. Analyses of the baseline data revealed marked differences in visceral adiposity/liver fat associated with glucose tolerance status. In both men and women, T2D diabetes is characterized by high levels of visceral adipose tissue/liver fat. A strong association between visceral adipose tissue and liver fat is found in both men and women. Excess visceral adiposity/liver fat is associated with a deteriorated cardiometabolic risk profile in patients with T2D.

Variants in vitamin D genes are associated with liver density and non-alcoholic fatty liver disease (NAFLD) in Hispanics and African Americans: the IRAS Family Study

K.A. Young[1], T.E. Fingerlin[2], L.E. Wagenknecht[3], C.D. Engelman[4], S.M. Haffner[5], C. Lorenzo[5], Y.-D. Chen[6], S.P. Sibbel[2], J.M. Norris[2];
[1]Colorado School of Public Health, Aurora, [2]Colorado School of Public School, Aurora, [3]School of Medicine, Wake Forest Univesity, Winston-Salem, [4]School of Medicine and Public Health, University of Wisconsin, Madison, [5]University of Texas Health Sciences Center, San Antonio, [6]Cedars Sinai Medical Center, Los Angeles, USA.

Background and aims: NAFLD is a condition that may be involved in the pathogenesis of type 2 diabetes, obesity, and the metabolic syndrome. Given the association between these factors and vitamin D status, we examined whether vitamin D pathway genes are associated with NAFLD in Hispanic- (HA) and African-Americans (AA), two ethnicities at increased risk for obesity, type 2 diabetes, and vitamin D deficiency.
Materials and methods: After eliminating 120 subjects with excessive alcohol intake, the IRAS Family Study examined 830 HA and 350 AA individuals from families in San Antonio, San Luis Valley and Los Angeles who had a computed tomography (CT) measure of the liver and visceral fat (VAT), and single-nucleotide polymorphism (SNP) data on *VDR* (15 SNPs), *DBP* (11 SNPs), *CYP27B1* (5 SNPs), *CYP24A1* (22 SNPs), and *CYP2R1* (3 SNPs) genes. The continuous outcome liver density was examined using a variance components approach, while the dichotomous outcome of NAFLD (liver:spleen density ratio < 1) was examined using generalized estimating equations (GEE); both analytic approaches account for the relatedness of the subjects. Additive models were

assumed for the SNPs. Models were adjusted for age, gender, admixture, and VAT. HA analyses were also adjusted for clinic site.
Results: In HA, mean age was 48.2 years, 63.4% were female, and mean VAT was 116.9 cm^2. In AA, mean age was 49.8 years, 60.2% were female, and mean VAT was 103.3 cm^2. 236 subjects were classified as having NAFLD (203 HA and 33 AA). *CYP27B1* and *CYP2R1* were not associated with liver density nor NAFLD in HA and AA. In HA, *DBP* and *VDR* were not associated with NAFLD, however, rs4334089 in *VDR* in was associated with liver density (p=0.027). In AA, while *DBP* and *VDR* were not associated with liver density, 3 SNPs in *DBP* and 1 SNP in *VDR* were associated with NAFLD. In AA, each copy of the A allele at rs10783219 in *VDR* resulted in 3.70 greater odds of having NAFLD (95% CI: 1.03-14.29); and for *DBP*, each copy of the T allele at rs4752 resulted in 3.09 greater odds of NAFLD (95% CI:1.51-6.34); each copy of the C allele at rs222020 resulted in 1.89 greater odds of NAFLD (95%CI: 1.08-3.33); and each copy of the G allele at rs10011000 resulted in1.96 greater odds of NAFLD (95% CI: 1.13-3.40). Several SNPs in *CYP24A1*were associated with liver density in AA [rs2248359 (p=0.036), rs3787554 (p=0.023), rs4809960 (p=0.044), rs6022999 (p=0.016)] and in HA [rs3787555 (p=0.013), rs6068816 (p=0.002), rs6097809 (p=0.029), rs6127119 (p=0.039)]. In addition, SNPs rs3787557 in AA and rs6068816 in HA were significantly associated with NAFLD. In AA individuals, each copy of the C allele at rs3787557 resulted in 2.60 greater odds of having NAFLD (95% CI: 1.33-5.07). In HA individuals, each copy of the C allele at rs6068816 resulted in 1.59 greater odds of having NAFLD (95% CI: 1.05-2.38).
Conclusion: In a two minority populations at increased risk for obesity and type 2 diabetes, variants in vitamin D pathway genes, particularly *CYP24A1*, are associated with liver density and NAFLD.

Using imputation to investigate association of low-frequency variants with adiposity in the 1966 Northern Finnish birth cohort
J.M. O'Connell[1], S. Ripatti[2], E. Zeggini[3], L. Peltonen[4], M.-R. Jarvelin[5], M.I. McCarthy[1], A.P. Morris[1], C.M. Lindgren[1];
[1]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [2]University of Helsinki, FIMM Institute for Molecular Medicine, Helsinki, Finland, [3]Wellcome Trust Sanger Institute, Cambridge, [4]Deceased, Cambridge, [5]Division of Epidemiology, Public Health and Primary Care, Imperial College London, United Kingdom.

Background and aims: Adiposity measures are known to be substantially heritable. While genome-wide association studies (GWAS) have identified over 20 common variants associatied with adiposity measures, less than 3% of the total heritability of adipose traits has been explained. One possible source of this missing heritablity is in low-frequency causal variants, say with minor allele frequency (MAF) <5%. Such variants pose several analytical challenges, due to a lack of statistical power for detecting association and their sparse availibility on current GWAS genotyping chips (by design). Here, we utilise genotype imputation and a novel statistical test of association to try and overcome these challenges.
Materials and methods: Given a set of SNPs for some individuals, imputation allows us to estimate genotypes at untyped variants in each individual by utilising a combination of population reference panels and a fine-scale recombination map. The recent release of 1000 Genomes pilot data (and already available HapMap3 data) allows us to impute the majority of low-frequency variants with MAF as low as 1%, as well as many much rarer variants. Using this newly available data, we test for association of gene regions with adiposity measures by considering the proportion of low-frequency and rare variants per genomic region at which individuals carry minor alleles in a linear regression framework. This method offers improved power over the traditional tests of association typically applied to common variants. Using this framework, four different adiposity phenotypes were investigated in the 1966 Northern Finnish Birth Cohort (genotyped using the Illumina HumanCNV-370DUO chip). We examined variants with MAF of <5% for association with BMI, hip circumference (HC), waist circumference (WC) and waist to hip ratio (WHR). Additional covariates were included in the model to adjust for population structure as well as sex. Models were also fitted separately for each sex.
Results: Imputation allowed us to investigate 89 514 and 1 121 653 variants with MAF <1% and <5% respectively, as opposed to the original GWAS data which contained 14 119 and 28 470 variants. The strongest signal of association over all genes and phenotypes was with WHR adjusted for BMI in males on a region of chromosome 7 ($p=2.1x10^{-8}$, allelic effect β=-0.23 [-0.31, -0.15]). In addition to this, a total of nine genes demonstrated strong evidence of association ($p<10^{-5}$) with the adiposity measures investigated. A further ten genes with nominal evidence of association ($p<10^{-4}$), but with plausible biological roles in adiposity have been highlighted for further investigation. For example, three genes on chromosome 11; PNPLA2, RPLP2 and TSPN4, had $p<10^{-4}$ and are all reported to be preferentially expressed in adipose tissue.
Conclusion: A number of novel possible adiposity associated genomic regions have been identified for follow up. Many of the identified regions have previously been identified as having plausible biological roles in adiposity and these regions are currently being sequenced in individuals at the extremes of the phenotypes.

***MC4R* gene variant rs17782313 (C/T) is associated with increased muscle mass in lean women**
O. Bradnova[1,2], M. Vankova[1], P. Lukasova[1], J. Vcelak[1], H. Kvasnickova[1], K. Vondra[1], J. Vrbikova[1], B. Bendlova[1];
[1]Molecular Endocrinology, Institute of Endocrinology, [2]Dep. of Anthropology and Human Genetics, Charles University, Prague, Czech Republic.

Background and aims: Melanocortin-4 receptor (*MC4R*) plays a critical role in regulating food intake and energy balance. MC4R activation in brain reduces food intake and increases energy expenditure via leptin signaling. MC4R deficiency is the most common form of monogenic obesity. Recently, the meta-analysis of 15 genome-wide association studies strongly confirmed the association of the common polymorphism rs17782313 lying 188 kb downstream of the *MC4R* gene with body mass index (BMI) and obesity risk in adults and children. We examined the impact of the rs17782313 (C/T) on obesity in cohort of Czech women and studied its possible metabolic effects.
Materials and methods: Polymorphism was assesed by ABI TaqMan SNP Genotyping Assay in 951 non-diabetic normoglycaemic women: 128 lean (age 26.4±5.86 years; BMI 18.9±0.92 kg/m^2), 409 normal weight (age 30.4±9.84 years; BMI 22.3±1.38 kg/m^2), 208 overweight (age 37.8±13.65 years; BMI 27.3±1.39 kg/m^2) and 206 obese women (age 38.6±13.86 years; BMI 34.9±4.11 kg/m^2). All women were detailed anthropometrically and biochemically characterized including oGTT and ITT tests. For statistical analyses the Mann-Whitney test and Chi-square test were used (NCSS 2004).
Results: Genotypes were in Hardy-Weinberg equilibrium. The allelic frequencies did not differ among groups (risk minor C allele: lean 33.2%; normal 27.3%; overweight 26.9%; obese 29.1%). The frequency of the minor allele corresponds to the other European populations. In the whole group of pooled women (age 30.5±9.28 years; BMI 24.9±5.54 kg/m^2), the carriers of the minor C allele (CC+CT) did not differ in BMI in comparison with non-carriers (TT) and surprisingly, they had significantly lower WHR (0.82 vs. 0.84, p=0.046) and waist circumference (73.8 vs. 75.9 cm, p=0.035) and higher serum creatinine level (69.9 vs. 66.9 umol/L, p=0.005). These effects were most apparent in the subgroup of lean women with BMI<20 kg/m^2 where the C allele carriers had significantly lower WHR (0.78 vs 0.82, p=0,001), waist (65.6 vs. 66.9 cm, p=0.02) and abdominal circumference (69.5 vs. 74.9 cm, p=0.008), higher % of muscle mass (41.3 vs. 39.1, p=0.0001) and higher creatinine levels (73.4 vs. 64.2 umol/L, p=0.02). In the sugroup of obese women with BMI > 30 kg/m^2, the association of the C allele with anthropometric parameters was not found, but the C allele carriers tend to be more obese and had also increased creatinine levels compared to non-carriers (69.8 vs. 61.9 umol/L, p=0.01).
Conclusion: We did not confirm the association of rs17782313 with obesity in our cohort of women. However, the C allele carriership was associated with increased creatinine levels and increased % of muscle mass, especially in lean women.

The effect of birth weight on obesity is not modified by *FTO* rs9939609
K. Færch[1], K. Pilgaard[1], E.A. Andersson[2], M.N. Harder[2], D.R. Witte[1], C. Pisinger[3], T. Jørgensen[3,4], O. Pedersen[2], T. Hansen[2], A.A. Vaag[1];
[1]Steno Diabetes Center, Gentofte, [2]Hagedorn Research Institute, Gentofte, [3]Research Centre for Prevention and Health, Glostrup, [4]Faculty of Health Sciences, University of Copenhagen, Denmark.

Background and aims: Increased birth weight and the *A* allele of *FTO* rs9939609 are both associated with adult obesity. However, it is unknown

whether the effects of birth weight and *FTO* variation are additive or whether the *FTO* risk variant modifies the effect of birth weight on adult obesity. Thus, the aim of this study was to examine whether there is an interaction between birth weight and the *FTO* rs9939609 on the development of adult obesity.
Materials and methods: Baseline data from the Danish population-based Inter99 study were used. Birth weight data on 4,584 participants (all singletons) were collected through midwife journals from the Danish State Archives. The *FTO* rs9939609 was genotyped using KASPar® technology (n=4,371). Obesity was assessed by body mass index (BMI). Age- and sex-adjusted linear regression analyses with BMI as outcome were performed. Model 1 allowed for interaction between birth weight and *FTO* rs9939609, whereas model 2 only included main effects of birth weight and *FTO* rs9939609.
Results: Mean BMI in the population was 26.11 kg/m^2 (SD: 4.5), mean age was 46.3 years (SD: 7.9), and 46.5% were men. There was no interaction between birth weight and the FTO rs9939609 variant on adult BMI (P=0.23, model 1), but both birth weight and FTO rs9939609 were independently associated with adult BMI in model 2. One kg increase in birth weight was associated with an increase in adult BMI of 0.46 kg/m^2 (95% CI: 0.20-0.71, P<0.001). Likewise, the *A* allele of FTO rs9939609 was associated with an increase in BMI of 0.49 kg/m^2 (95% CI: 0.30-0.68) per risk allele (P<0.001) assuming an additive genetic model.
Conclusion: The effect of birth weight on obesity in adult life is not modified by the FTO rs9939609 variant in the Danish population. Thus, *FTO* variation and birth weight contribute independently to adult obesity.

GIP receptor polymorphism rs10423928 affects body mass index and insulin and glucagon response after ingestion of glucose or mixed meals in Japanese

D. Yabe, K. Watanabe, Y. Kitamoto, K. Sugizaki, K. Sugawara, M. Hishizawa, T. Hyo, T. Kurose, Y. Seino;
Division of Diabetes, Clinical Nutrition and Endocrinology, Kansai Electric Power Hospital, Osaka, Japan.

Background and aims: GIP enhances insulin and glucagon secretion, and regulates fat deposition and bone formation through binding to GIP receptor (GIPR). Recent study showed an association of a single nucleotide polymorphism (SNP) in the human GIPR gene, rs10423928 with elevated post-challenge plasma glucose levels. To evaluate effects of this SNP, as well as SNPs in KCNQ1 and TCF7L2, on secretion of insulin and glucagon, we measured levels of insulin, glucagon and glucose in response to ingestion of glucose or mixed meal in Japanese untreated type 2 diabetes (T2DM), impaired glucose tolerance (IGT) and healthy controls.
Materials and methods: Japanese healthy controls (n=33, age 46±;2, HbA1c 5.2 ±;0.0%, BMI 21.6±;0.5), IGT (n=24, age 56±;2, HbA1c 5.9±;0.3%, BMI 23.7±;0.5) and untreated T2DM (n=22, age 58±;2, HbA1c 6.3±;0.1%, BMI 23.3±;0.4; duration 1.9±;0.4 years) were subjected to 75-g oral glucose and 480-kcal meal tolerance tests (OGTT and MTT, respectively) and their glucose, insulin and glucagon levels were measured. SNPs were genotyped by an allele-specific primer PCR method using peripheral leukocyte DNA of each subject.
Results: Allele frequencies of SNPs in each group were as follows: GIPR rs10423928 Controls, AA 0.2/AT0.3/TT0.5; IGT, AA0/AT0.3/TT0.7; T2DM, AA0/AT0.4/TT0.6; KCNQ1 rs2237892 Controls, CC0.4/CT0.4/TT0.1; IGT, CC0.4/CT0.4/TT0.2; T2DM, CC0.4/CT0.4/TT0.2; TCF7L2 rs7903146 Controls, CC0.9/CT0.1/TT0; IGT, CC0.9/CT0.1/TT0; T2DM, CC0.9/CT0.1/TT0. Parameters that are significantly different (unpaired t-test, p<0.05) between GIPR rs10423928 AA- and TT-carriers are as follows (Figure 1): BMI, glucose-AUC(0-120) in OGTT and MTT, and glucagon-AUC(0-120)in OGTT and MTT. Parameters related to insulin secretion (i.e. insulinogenic index, insulin-AUC(0-120), HOMA-beta) and insulin resistance (i.e. HOMA-IR) show no significant difference between AA- and TT-carriers, although insulin-AUC(0-120) in OGTT and MTT showed significance difference between AT- and TT-carriers. No parameter related to insulin and glucagon secretion shows significant difference among KCNQ1 rs2237892 CC-, CT- and TT-carriers. No parameter shows significant difference between TCF7L2 rs7903146 CC- and CT-carriers.
Conclusion: GIPR rs10423928 AA-carriers have significantly lower BMI, reduced glucagon secretion, and lower plasma glucose levels after ingestion of glucose or meal. In addition, GIPR rs10423928 also affects insulin secretion after ingestion of glucose or meal. Notably, no GIPR rs10423928 AA-carrier was found in IGT and T2DM of the current study. Although the subject number in the current study is limited, our results are consistent with roles of GIP in secretion of glucagon and insulin and fat accumulation, and strongly suggests that GIP dysfunction could play a role in pathogenesis of T2DM.

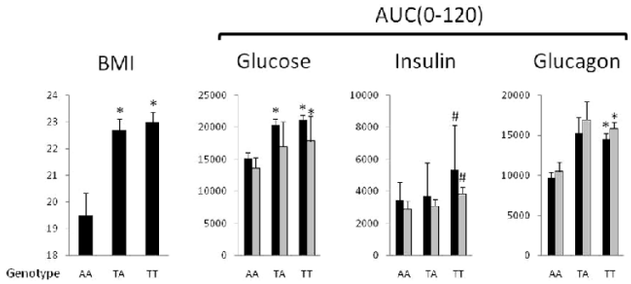

Figure 1. Effects of GIPR SNP on BMI and Levels of Glucose, Insulin and Glucagon. Mean±SEM. OGTT, black bars and MTT, gray bars.
* and #, Significant difference (unpaired t-test , p<0.05) versus AA and TA, respectively.

Replication initiator 1 gene (*Repin1*) is involved in the pathophysiology of human obesity

K. Dietrich[1], M. Kern[2], D. Schleinitz[1], J. Breitfeld[1], I. Mueller[1,2], B. Enigk[1], J. Kosacka[2], A. Toenjes[2], M. Stumvoll[2], M. Blueher[2], P. Kovacs[1], N. Kloeting[2];
[1]Interdisciplinary Centre for Clinical Research, [2]Department of Medicine, University of Leipzig, Germany.

Background and aims: The replication initiator 1 gene (*Repin1*) maps within a quantitative trait locus for obesity and is related to dyslipidemia in subcongenic rat strains. Here, we investigated the role of *Repin1* in the pathophysiology of human obesity.
Materials and methods: *Repin1* mRNA expression was measured in intraabdominal visceral (Vis) and abdominal subcutaneous (Sc) adipose tissue in 196 individuals with a wide range of metabolic phenotypes using RT-PCR (TaqMan, Applied Biosystems, Inc.). The *Repin1* was sequenced (exons, exon-intron boundaries, 5´and 3´ UTRs) in DNA samples from 48 non-related Caucasian subjects to identify genetic variants. 18 variants were identified, including a 12 bp deletion in exon four resulting in a final protein missing four amino acids (rs3832490; P356_A359del). The deletion and nine single nucleotide polymorphisms (SNPs) including six HapMap (www.hapmap.org) tagging SNPs representing their linkage disequilibrium groups were genotyped for subsequent association studies in two independent cohorts with detailed metabolic testing: German Caucasians from Leipzig (N=2194; mean age 56±15 years) and a self-contained population of Sorbs from Germany (N=1046; 48±16 years), totalling 3240 subjects. TaqMan assays were used for SNP genotyping and restriction fragment length polymorphism (RFLP) technique for the deletion.
Results: We found significant correlations between *Repin1* mRNA expression in human Vis and Sc adipose tissue and total body fat mass as well as adipocyte size, suggesting *Repin1* as novel candidate gene for human obesity and related traits. In a case control study including 1018 subjects with type 2 diabetes (T2D) vs. 616 subjects with normal glucose tolerance (NGT), three SNPs (rs3735170, rs10278590, rs1051760) were significantly associated with T2D (P<0.05 after adjusting for age, sex and BMI) in the Leipzig cohort. In subjects with NGT, rs4725336 was significantly associated with cholesterol, rs9640161 with HbA1c, and rs3832490 (P356_A359del) with % body fat and 2 hr glucose (adjusted P<0.05). In the self-contained population of the Sorbs, rs4725336 showed association with obesity in a case control study including 397 obese (BMI>30 kg/m^2) vs. 234 lean (BMI<25 kg/m^2) subjects (adjusted P<0.05). Consistent with results from the Leipzig cohort, rs3832490 (P356_A359del) was moderately associated with % body fat in Sorbian subjects with NGT (N=835) and rs6971465 correlated with cholesterol and LDL-cholesterol (adjusted P<0.05).
Conclusion: Correlation of mRNA expression in adipose tissue with obesity as well as the association of *Repin1* genetic variants with T2D, obesity and relevant metabolic traits suggest a potential role of *Repin1* in the pathophysiology of human obesity.

PS 9 Epidemiology of type 1 diabetes mellitus: incidence and mortality

336

Estimate of incidence and prevalence of type 1 diabetes using electronic drug prescription archives

M. Maggini[1], R. Da Cas[1], C. Lunghi[2], F. Pricci[3];
[1]Epidemiology, National Institute of Health, Roma, [2]ProtEra, Sesto Fiorentino, [3]Cell Biology, National Institute of Health, Roma, Italy.

Background and aims: A very wide range of childhood diabetes incidence rates within Europe has been shown, but no recent data are available in Italy. Type 1 diabetes features are that is usually diagnosed in children and young adults, and causes dependence on insulin treatment for life. On the other hand, diabetes is the only indication for insulin therapy. Aim of this study was to estimate incidence and prevalence of type 1 diabetes among people 0-15 years old in the Lazio Region in the period 2005-2008, and to describe the insulin prescription pattern, using a record linkage between drug prescription and National Health Service (NHS) enrollee electronic archives.
Materials and methods: The Italian NHS provides antidiabetic drugs free of charge to all citizens. Data on outpatient antidiabetic drug use were obtained from the Regional drug prescription monitoring database for the period 2005-2008. Data on characteristics of population exposed to the study drugs were derived from Lazio (about 6 millions inhabitants) database of NHS enrollees, which contains demographic data of residents. The two databases can be linked by a unique individual code allowing to trace back an hystorical patient drug profile. Patients were considered as "prevalent" cases if they received insulin (ATC A10A - insulins and analogs) prescriptions during the study period. "Incident" case was defined as a patient who received the first insulin prescription in the period 2006-2008, without any antidiabetic prescription in the previous 12 months. The date of the first insulin prescription was used as date of diagnosis.
Results: An annual mean of 692 type 1 diabetes cases were identified in the four-year study period. The prevalence of diagnosed type 1 diabetes increased from 81 (CI 95% 74-87) per 100,000 inhabitants in 2005 to 91 (CI 95% 84-97) in 2008 with no evidence of a difference between boys and girls. The prevalence rates increase with age, in 2008 they were 20 per 100,000 (CI 95% 11-28) for children aged 1-3 years, and 173 (CI 95% 156-191) for 12-15 years. A total of 469 incident cases were identified from 2006 through 2008. The cumulative incidence varied from 21 (CI 95% 17-24) per 100,000 in 2006 to 17 (CI 95% 14-19) in 2008. At the first prescription, the majority of children received rapid-acting human insulin and analogs. Overall, with respect to 2005 there was a shifting of prescriptions to long-acting insulin.
Conclusion: The estimated incidence is quite higher from that previously reported for Lazio: 8.1 per 100,000 in the period 1993-94. Our study shows a limited increase in the prevalence rates of diagnosed type 1 diabetes among children 0-15 years from 2005 through 2008. However, the study period was too short to investigate a time trend in incidence and prevalence. Completeness of ascertainment is being evaluated through a validation procedure with the data of one of the most important diabetic centre of the Region. The use of routinely collected data to estimate incidence and prevalence of type 1 diabetes, and to identify cohorts of patients, may represent an alternative to other costly and time consuming methods.

337

Increasing incidence of childhood onset type 1 diabetes in Norway

T. Skrivarhaug[1], L.C.M. Stene[2], H. Strøm[2], A.K. Drivvoll[1], P.R. Njølstad[3], G. Joner[1], The Norwegian Childhood Diabetes Study Group;
[1]Dept of Pediatrics, Oslo University Hospital, Ulleval, [2]Division of Epidemiology, Norwegian Institute of Public Health, Oslo, [3]Dept of Pediatrics, Haukeland University Hospital, Bergen, Norway.

Background and aims: There is a worldwide increase of type 1 diabetes (T1DM). In 1989, the Norwegian population-based childhood diabetes register was initiated including all newly diagnosed children aged 0-14 years with diabetes. All 26 paediatric departments in Norway reports new cases of childhood diabetes to The Norwegian Childhood Diabetes Register based on informed consent from the child and/or parents. Since 2004 the Prescription Database (NorPD) at the National Institute of Public Health has registered all drug prescription in Norway, including insulin. Data published by the authors previously showed a clear increasing trend during the period 1973 - 2003 with IR moving from 19.1/10^5 in 1973 to 28.9/10^5 in 2001-2003. The aim of the study was to determine the incidence of T1DM in children 0-14 years in Norway during 2005-2008, and to calculate the ascertainment in the nationwide Norwegian Childhood Diabetes Register during the same period.
Materials and methods: During the study period 2005-2008,1232 new cases of childhood onset diabetes were registered by The Norwegian Childhood Diabetes Register. Of these, 1144 were classified as T1DM and were below 15 years at onset. Information on individual insulin prescriptions was obtained from The Prescription Database, and the first prescription of insulin 2004-2008 was registered and assumed to be at a date close to onset of T1DM. Consequently, "new cases" in the NorPD could only be defined for the years 2005-2008. The assumption of source independence and equal probability of capture of each case by these two sources is verifiable. This is the first time these two registries are linked with the purpose to give information about incidence of childhood T1DM and completeness of The Norwegian Childhood Diabetes Register.
Results: In the period 2005-2008, the uncorrected incidence rate of T1DM 0-14 years was 32.4 /10^5/year for both sexes, for boys 34.1*10^5 and for girls 30.9*10^5, which indicates an steadily increasing trend compared to previously published incidence rates. The Prescription Database contained data on first time insulin prescriptions in 115 subjects, not reported to the diabetes register and the completeness is calculated to 92 % for the whole study period which is appropriate according to the criteria for entering national data into the EURODIAB study.
Conclusion: The incidence of type 1 diabetes has further increased in Norway as in many other European countries. The incidence has been studied nationwide since 1989 and the completeness of registration of new cases can be documented to be 90-95% % in all periods with obligatory signed informed consent forms from all patients.

338

The influence of birth cohort on the incidence of childhood type 1 diabetes in Wales

J.N. Harvey[1], R. Hibbs[1], H. O'Connell[2], J.W. Gregory[2], on behalf of the Brecon Group;
[1]Centre for Endocrinology & Diabetes, Wales College of Medicine, Wrexham, [2]Paediatrics, Wales College of Medicine, Cardiff, United Kingdom.

Background: It is suggested that type 1 diabetes (T1DM) occurs when genetically susceptible individuals experience a viral infection in the period preceding diagnosis: a period effect. There is also evidence that perinatal factors influence the incidence of T1DM in childhood. Systematic change in these would produce a birth cohort effect meaning an effect from being born at a particular time or having shared experience with those born at the same time.
Aims: To examine the influence of period and birth cohort on the incidence of T1DM in children aged <15y in Wales from 1995-2008.
Materials and methods: Information on 2046 cases diagnosed with T1DM from 1995-2008 was obtained prospectively from all paediatric units in Wales. Ascertainment was >95% in each calendar year to 2006.
Results: The overall increase in incidence (poisson regression modelling) assuming continuous linear growth was 1.9% per annum (residual deviance 0.84, $p<0.001$) but best fit was obtained with a model showing no further increase in incidence rate since 2000 (residual deviance <0.7, $p<0.001$) with no further increase in cases before age 5. The current annual incidence rate is 28 cases per 100,000 children. Modelling the influence of birth cohort suggests an effect of approx 1.5 on incidence rate when birth cohorts since 1985 are compared with 1980-84 and that this effect has not increased since 1985. Adding period effect produces a less good model (residual deviance 1.27, $p<0.001$) but indicates that an increasing period effect is counterbalanced by a reducing birth cohort effect.
Conclusion: The incidence rate of T1DM has not increased in Wales since 2000. Birth cohort effects have more influence than period effects and the absence of any continuing increase in birth cohort effect in Wales is a major influence on the incidence rate. Perinatal factors therefore require further investigation. Differences in the relative contribution of birth cohort and period effects on incidence compared to other nations may explain the current plateau in incidence in Wales.

339

Incidence of childhood and youth type 1 diabetes in La Palma Island 1993-2009

B.M. Belinchón[1], J.A. Hdez.-Bayo[2], S. Vázquez Dieguez[3];
[1]Family Care, S/C La Palma, [2]Endocrinology, General Hospital of La Palma, Breña Alta, [3]Pediatrics, General Hospital of La Palma, Breña Alta, Spain.

Background and aims: The incidence of type 1 diabetes shows wide geographical variability and heterogeneity. The aim of this study was to determine the incidence of type 1 diabetes in children and young people younger than 30 yr in La Palma Island (the most northwest of Canary Islands, Spain: 730 Km^2, 85000 habitants and subtropical climate).
Materials and methods: All subjects with type 1 diabetes (according WHO and/or ADA criteria) diagnosed between January 1993 and December 2009 (prospectively 1995-2009) were included. The population at risk (0-29 yr) fluctuated between 36419 habitants (15711 habitants younger than 15 yr) -1991 General Census- and 29620 (11899 habitants younger than 15 yr) -2001 General Census-. All the reported cases were on insulin treatment. All subjects were living in La Palma Island at least six months before diagnosis of type 1 diabetes. Using the capture-recapture method (primary source was hospital records, while secondary sources were membership files of La Palma Diabetic Association and Primary Care Physicians), the ascertainment was 100 %. The incidence rates were expressed as number of cases per 10^5 habitants per year. The 95% Confidence Intervals were estimated assuming the Poisson distribution of the cases. The age adjustment for the rates was done using the direct method with a World and European Standard Population.
Results: 113 subjects younger than 30 yr had presented type 1 diabetes at the last 17 yr (64 boys, 49 girls; medium age: 13±7.6 yr). The annual incidence fluctuates between 5.8 and $33.7/10^5$, being the average annual incidence $20.8/10^5$ (95% CI: 18.6-23; $34/10^5$ in the 0-14 yr group, CI 95%: 31.2-36.8; $11.6/10^5$ in the 15-29 yr group, CI 95%: 10-13.2) without sex differences ($21.4/10^5$ per yr in boys versus $17.3/10^5$ per yr in girls). The incidence was higher in the 5-9 yr age-group ($39.6/10^5$ per yr), followed by the 10-14 yr age-group ($38.4/10^5$ per yr), the 0-4 yr age-group ($21.9/10^5$ per yr), the 25-29 yr age-group ($13/10^5$ per yr), the 15-19 yr age-group ($12.8/10^5$ per yr) and the 20-24 yr age-group ($9/10^5$ per yr). The age-adjusted incidence to World Standard Population was $23.1/10^5$ per yr (95% CI: 20.8-25.4; $32.4/10^5$ in the 0-14 yr group, $11.6/10^5$ in the 15-29 yr group]. The age-adjusted incidence to European Standard Population was $22.4/10^5$ per yr (95% CI: 20.2-24.6; $32.8/10^5$.in the 0-14 yr group, $11.6/10^5$ in the 15-25 yr group).
Conclusion: The incidence of type 1 diabetes in La Palma Island is the highest reported up to date in a Spanish community, and is close to the highest of the world. It is inconsistent with the hypothesis of a north-south gradient in diabetes risk. The knowledge of the incidence rates in La Palma Island can contribute to study the role that genetics and environmental factors may play in these differences.

340

Prospective nation wide registration of type 1 diabetes incidence in 0-34 years old during 25 years - a shift to younger age at diagnosis

G.G. Dahlquist[1], L. Nyström[2], C.C. Patterson[3], Swedish Childhood Diabetes Study Group and Diabetes Incidence in Sweden Study Group;
[1]Clinical Science, Pediatrics, Umeå university, [2]Public Health and Clinical Medicine, Epidemiology, Umeå University, Sweden, [3]Department of Epidemiology and Public Health, Queen's University, Belfast, United Kingdom.

Background and aims: To clarify if the increase in childhood type1 diabetes is mirrored by a decrease in older age groups on a birth cohort basis and to test the hypothesis that autoimmune diabetes shifted to younger age at onset. To test if cohort effects dominated over calendar period effects.
Materials and methods: The data base included 20 249 individuals with diabetes onset 1983 to 2007 combining data from two prospective research registers, the Swedish Childhood Diabetes Register including cases 0-14.9 years at onset and the Diabetes in Sweden Study including cases 15-34.9 years at onset. Incidence rates over time were analyzed using Poisson regression models.
Results: The overall yearly incidence rose to a peak of 42.3 per 100000 in males10-14 years and of 37.1 in females 5-9 years age group and decreased thereafter with increasing age. There was a significant increase by calendar year in both sexes in the three under 15 years' age groups but decreases in the older age groups with significant decreases in the two age groups over 25.A cohort effect dominated over the time period effect.
Conclusion: Twenty-five years of prospective nationwide incidence registration demonstrates a clear shift to younger age at onset rather than a uniform increase in incidence rate across all age-groups. Exposures that affect young children more than older children and adults and accelerates disease onset may be responsible.

Ethnic differences in incidence rates of childhood type 1 diabetes in Yorkshire 1978-2007

K. Harron[1], P.A. McKinney[1], R.G. Feltbower[1], C.R. Stephenson[1], P.D. Norman[2], H.J. Bodansky[3], G. Chhokar[4], R.C. Parslow[1];
[1]Paediatric Epidemiology Group, University of Leeds, [2]School of Geography, University of Leeds, [3]Leeds General Infirmary, [4]St. James University Hospital, Leeds, United Kingdom.

Aims: To examine incidence rates and trends of childhood Type 1 diabetes in Yorkshire from 1978-2007.
Materials and methods: Data from the population-based Yorkshire Register of Diabetes in Children and Young People was used to analyse the incidence of Type 1 diabetes in children aged <15 years diagnosed in the former Yorkshire Regional Health Authority. Incidence rates (per 100,000 per year) were estimated using mid-year population estimates stratified by sex, age and ethnicity: south Asian (Indian, Pakistani, Bangladeshi) or non-south Asian (all other ethnicities). Ethnicity was assigned using two name recognition programs (Nam Pehchan and SANGRA) and a local expert. Age-sex standardised rates were calculated between 1978-2007 and by ethnic-group between 1990-2007. Poisson regression was used to assess incidence trends and estimate predicted rates up to 2020. Goodness-of-fit, AIC and likelihood-ratio tests were used to assess model fit.
Results: 3911 children were diagnosed in Yorkshire between 1978-2007. Overall incidence was 18.1 (17.6-18.7) and lowest among 0-4 year-olds compared to 5-9 and 10-14 year-olds: 11.7 (95% CI 10.9-12.5), 18.6 (17.6-19.6) and 23.7 (22.6-24.8) respectively. Incidence increased significantly over time with an average annual percentage change (AAPC) of 2.9% (2.5-3.2). The AAPC differed slightly between age-groups - 0-4: 2.6% (1.7-3.4), 5-9: 3.2% (2.6-3.8) and 10-14 years: 2.8% (2.2-3.3). The inclusion of an age-sex interaction term provided evidence for differences in trends between sexes depending on age, with females having higher incidence and AAPC than males for those aged 5-9. Incidence for non-south Asians (21.6 (20.7-22.4)) was significantly higher than that of south Asians (14.7 (12.4-17.1)) over the entire study period. A significant increasing trend in incidence was observed for non-south Asians of 3.4% (2.7-4.2) compared to a non-significant trend seen in south Asians (1.5% (-1.5, 4.5)). Overall forecasted incidence for 2020 is 38.8.
Conclusion: Type 1 diabetes incidence rates have continually risen over the last three decades for non-south Asians of all ages but not for south Asians, whose families come from a low incidence area. This is contrary to findings in the Bradford area of Yorkshire between 1978-1998. Overall incidence increased most quickly in the 5-9 age-group. Incidence doubled from 12.5 to 25.6 between 1978-2007. If current trends continue, rates will rise by 52% to 38.8 between 2007-2020.

Long-term mortality and causes of death among patients with type 1 diabetes in Japan

A. Morimoto, R. Nishimura, H. Sano, T. Matsudaira, N. Tajima, K. Utsunomiya;
Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.

Aims: To investigate long-term prognosis including causes of death among patients with type 1 diabetes in Japan.
Methods: A total of 1,387 patients (556 males and 831 females) were registered from two nationwide type 1 diabetes surveys in Japan. They were diagnosed as type 1 diabetes at less than 18 years of age between 1965 and 1979. All patients were tracked for survival status until January 1, 2005, with this status determined based on the questionnaires sent to their attending physicians or the residents' records. Causes of death were identified through questionnaires or death certificates. Their survival status as of January 1, 2005 was expressed in terms of standardized mortality ratio (SMR) and crude mortality rate (CMR). Mortality was compared between the male and female patients by using the Cox proportional-hazards model. The causes of death for deceased cases were divided into 9 groups (1. diabetic renal disease; 2. acute diabetic complications; 3. accident/suicide; 4. cardiovascular disease; 5. infections; 6. malignant neoplasms; 7. other non-diabetic causes; 8. other diabetic causes; 9. unknown) and were also compared by duration of diabetes. Statistical analyses were performed by using SAS 9.1.
Results: The mean age at diagnosis was 8.8 ± 4.1 (SD) years, with a duration of diabetes of 27.9 ± 6.4 years. One thousand one hundred and three patients were confirmed as alive as of January 1, 2005, and 223 deaths (16.1%) were observed (confirmation rate: 95.6%). The SMR was 10.6 (males, 9.6; females 14.3), and the CMR was 658/100,000 person-years (males, 778; females, 579). The male patients were shown to be at 1.37-fold higher mortality risk compared to the female patients (95% CI, 1.02-1.85). The causes of death identified included diabetic renal disease (51 patients; 22.9%), cardiovascular disease (40; 17.9%), acute diabetic complications (38; 17.0%), infections (34; 15.3%), accidents and suicides (21; 9.4%), unknown cause (18; 8.1%), other non-diabetic causes (13; 5.8%), other diabetic causes (6; 2.7%), and malignant neoplasms (2; 0.9%). Leading causes of death included acute diabetic complications among those with less than 10 years' duration of disease, diabetic renal disease among those with 10 to 20 years' duration, infections among those with 20 to 30 years' duration, and cardiovascular disease among those with 30 to 40 years' duration. Thus, the longer the duration of disease, the less the mortality from acute diabetic complications, and the greater the mortality from cardiovascular disease. The time from the initiation of dialysis to death was shown to be 5.5 ± 4.8 years in 89 patients who were confirmed to have been dead after initiation of dialysis.
Conclusion: The mortality risk of patients diagnosed as type 1 diabetes between 1965 and 1979 in Japan was shown to be 10.6-fold higher than that of the general population. The males were found to be at 1.37-fold higher mortality risk than the females. Diabetic renal disease, cardiovascular disease and acute diabetic complications were found to be the leading causes of death. However, as the duration of disease became longer, acute diabetic complications contributed less and cardiovascular disease contributed more to mortality.

First trimester cytokine levels in mothers to children diagnosed with islet autoimmunity or type 1 diabetes before eight years of age

S.R. Resic Lindehammer[1], M. Fex[1], K. Marsal[2], Å. Lernmark[1];
[1]Diabetes and Celiac Disease, Clinical Sciences, Malmoe, [2]Department of Obstetrics and Gynecology, Clinical Sciences, Lund, Sweden.

Background and aims: Gestational infections and/or stress have with conflicting results been associated with an increased type 1 diabetes risk in offspring. Using multi-array analysis of cytokines, we tested whether Th1/Th2 cytokines during the first trimester were different between mothers who gave birth to children who developed islet autoimmunity at 1-8 years of age and matched control mothers.
Materials and methods: First trimester serum samples were analyzed for IFNγ, IL-10, IL-12, IL-13, IL-1β, IL-2, IL-4, IL-5, IL-8 and TNFα using the Meso-Scale Multi-Array system (MesoScale, Gaithersburg, Maryland). We compared 53 non-diabetic mothers who gave birth to a child who developed at least two islet autoantibodies against either GAD65, IA-2 or insulin with increasing levels at the second, third, fourth or fifth year of follow-up (a total of 40 children developed type 1 diabetes before 8 years of age) with 106 non-diabetic control mothers which were matched by age, HLA genotype as well as first trimester sampling date. The mothers included in this study are participating in the Skåne Diabetes Prediction Study (DiPiS). In 2000-2004, DiPiS recorded 48 058 live births with the aim to determine etiology indicators of type 1 diabetes. Blood samples (both mothers serum and cord blood) were obtained at the time of delivery in 75% of the 48 058 recorded live births, and first trimester samples (10-16 gestational weeks) were available from the Southern Sweden Microbiological biobank for the non-diabetic mothers included in this part of the study.
Results: The median of IFNγ (p=0.02) and IL-1β (p=0.04) levels were significantly higher in the index mothers compared to the matched controls. The mean length of gestation in the index mothers was 275 days compared to 280 days in control mothers (p=0.04). The shortened gestational length was not related to the IFNγ or IL-1β levels. However, the gestational length in index but not control mothers was significantly correlated to IL-10 (p=0.03), IL-12 (p=0.01), IL-13 (p=0.04), IL-2 (p=0.04) and IL-5 (p=0.008).
Conclusion: This study revealed that 1) index mothers had elevated Th1 mediated cytokines (IFNγ and IL-1β) during the first trimester; 2) gestational length was significantly shortened in the index mothers; and that 3) several Th2 mediated cytokines were inversely related to the gestational length in the index but not in the control mothers, in first trimester samples. We therefore conclude that an increase in Th1 cytokine levels during the first trimester may signify gestational infection or stress. Furthermore, we conclude that Th2 cytokines may affect gestational length. In summary, these aberrations may contribute to an increased risk for islet autoimmunity and subsequent development of type 1 diabetes in the offspring.

First trimester serum cytokine levels and the development of autoimmune disease in offspring

M. Fex[1], S. Björck[1], K. Lynch[1], C. Brundin[1], K. Marsal[2], D. Agardh[1], S.R. Resic Lindehammer[1];
[1]Diabetes and Celiac Disease, Lund University, Malmö, [2]Department of Obstetrics and Gynecology, Lund University Hospital, Lund, Sweden.

Background and aims: Pregnancy involves local and systemic changes in the balance between the Th1 and Th2 immunological response. It is generally accepted that pregnancy is mediated by a Th2 response inducing tolerance in the mother towards the fetal allograft. Several studies suggest that a shift in the Th1/Th2 balance during pregnancy caused by underlying environmental factors could be associated with post-partum autoimmune disease in the offspring. In this study we used Celiac disease as a model to investigate if autoimmunity is triggered already *in utero* during early pregnancy, observed as changes in the mother's cytokine profile.
Material and methods: Ten cytokines were measured by electro chemi-luminiscent multiplex ELISA in serum samples obtained from mothers during the first trimester. Cases included women with children who before the

age of 5 developed verified Celiac disease. Matched controls were selected based on age, Celiac Disease associated HLA genotype and serum sampling date. Mann-Whitney U tests first tested for a significant overall shift in cytokine levels in cases compared to controls. Chi-square tests further examined whether the cases were distributed evenly across quartiles ranges of the control distribution.
Results: We observed that seven out of ten cytokines were significantly increased in the cases when compared to matched controls. Five of the cytokines were Th1 mediated (TNFα, IFNγ, IL-2, IL-1β, IL-12), and two were Th2 mediated cytokines (IL-13 and IL-10). In the matched case-control analysis, the three top cytokines were shown to be: TNFα (p=0.002), IL-13 (p=0.002) and IFNγ (p=0.005) which all were all elevated in the case group.
Conclusion: A delicate balance between Th1/and Th2 mediated cytokines is required to ensure a successful pregnancy. However, changes in this balance could predispose the fetus to future disease. In this study we show that autoimmunity in children is triggered already during early pregnancy and can be observed as quantitative changes in the serum cytokine levels of pregnant mothers.

Maternal serum 25-hydroxy-vitamin D during late pregnancy and risk of type 1 diabetes in the offspring
L.C.M. Stene[1], I.M. Sørensen[2], P.A. Torjesen[3], P.A. Jenum[4], A. Eskild[5], G. Joner[2,6];
[1]Division of Epidemiology, Norwegian Institute of Public Health, Oslo, [2]Department of Paediatrics, Oslo University Hospital Ullevål, Oslo, [3]Hormone Laboratory, Oslo University Hospital Aker, Oslo, [4]Department of Microbiology, Asker and Bærum Hospital, Bærum, [5]Department of Obstetrics and Gynaecology and Medical Faculty Division, Akershus University Hospital, University of Oslo, [6]Institute of Health and Society, University of Oslo, Norway.

Background and aims: A few case-control studies and one cohort study have suggested that use of vitamin D supplement in childhood or by the mother during pregnancy may be associated with lower risk of type 1 diabetes in children. However, vitamin D status is influenced not only by dietary intake (from food and supplements) but also skin exposure to ultraviolet light. No published study has yet reported the possible relation between the serum level of 25-hydroxy-vitamin D, which is a good marker of the integrated effects of dietary and endogenous sources of vitamin D, and the risk of type 1 diabetes. We aimed to test whether higher maternal serum concentration of 25-hydroxy-vitamin D during late pregnancy predicts a lower risk of childhood onset type 1 diabetes in the offspring.
Materials and methods: Based on a prospective cohort of nearly 30 000 pregnant women who gave birth in Norway during 1992-94, we analysed serum samples from 99 pregnant women whose child developed type 1 diabetes before 15 years of age and 155 randomly selected control women whose child did not develop type 1 diabetes during follow-up. The sera were collected around week 37 of pregnancy and stored at -20°C until analysed in 2008/9. Cases were identified by record linkage to The Norwegian Childhood Diabetes Registry. Serum 25-hydroxy-vitamin D was analysed using a radio immunoassay (DiaSorin). Power calculations showed 88% power to detect a significant association with a test for trend over quartiles with 100 cases and 150 controls, assuming an odds ratio of 0.33 comparing the upper vs. lower quartile of 25-hydroxy-vitamin D and a logit-linear dose-response relation.
Results: There were no significant differences between cases and controls in demographic data. The mean level of 25-hydroxy-vitamin D in cases was 66.4 nmol/l and in controls 71.5 nmol/l, odds ratio (per nmol/l): 0.9 (95% CI 0.9-1.0, p=0.1). Comparing the 4th vs. 1st quartile of maternal serum 25-hydroxy-vitamin D, the odds ratio was 0.6 (95% CI 0.3-1.3). Test for trend over quartiles: p=0.2. Adjustment for season of blood collection, maternal diabetes or other potential confounding variables did not influence these results.
Conclusion: In this first study to test the hypothesis that high serum 25-hydroxy-vitamin D status during pregnancy predicts a lower risk of type 1 diabetes in children we found no statistically significant association despite a suggestive trend.

No association of human enterovirus RNA in monthly faecal samples and islet autoimmuinity in the Norwegian MIDIA study
G. Tapia[1,2], O. Cinek[2], T. Rasmussen[1], E. Witsø[1], B. Grinde[3], L.C.M. Stene[1], K.S. Rønningen[1];
[1]Department of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway, [2]Second Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Department of Virology, Norwegian Institute of Public Health, Oslo, Norway.

Background and aims: To test whether the frequency of human enterovirus RNA in faecal samples collected monthly from early infancy was associated with development of multiple islet autoantibodies in children with the highest risk HLA genotype.
Materials and methods: Individuals carrying the HLA-DRB1*0401-DQA1*03-DQB1*0302/DRB1*03-DQA1*05-DQB1*02 genotype were identified at birth and followed with monthly stool samples from 3 to 35 months. Blood samples taken at age 3, 6, 9, 12 months, and then annually, were tested for autoantibodies to insulin, glutamic acid decarboxylase 65 and protein tyrosine phosphatase IA-2. Twenty seven children developed positivity for at least 2 islet autoantibodies in 2 or more consecutive samples (cases). Two matched controls per case were selected. Stool samples from these children were analyzed for enterovirus with a semiquantitative real-time reverse transcriptase PCR. The frequency of enterovirus was modelled as the dependent variable and took account of the intra-individual correlation in enterovirus infection using a random intercept for the enterovirus infection. The data was also analysed using conditional logistic regression modelling with islet autoimmunity as the outcome.
Results: The frequency of enterovirus RNA in stool samples from cases prior to seroconversion (43/339, 12.7%) did not differ from the frequency in matched controls (94/692, 13.6%); odds ratio=1.01 (95% CI: 0.59 - 1.72), P=0.97. Results remained essentially unchanged after adjustment for potential confounders, restriction to various time windows before seroconversion, infections in the first year of life, or after including samples collected after seroconversion. There was no difference in the average quantity of enterovirus RNA, or the frequency of repeatedly positive samples. In the conditional logistic regression analysis, the "odds ratio" per enterovirus infection was 1.12, with corresponding 95% confidence interval 0.66-1.91.
Conclusion: The data strongly suggest that faecal shedding of enteroviral RNA does not predict islet autoimmunity, as human enterovirus infections are not more frequent before or after autoantibodies appear.

347

Identification of type 1 diabetes-associated methylation variable positions that precede disease diagnosis
H. Beyan[1], V.K. Rakyan[1], T.A. Down[2], M.I. Hawa[1], S. Maslau[2], C. Wallace[3], D. Aden[1], C.A. Mein[4], B. Manfras[5], A. Curtotti[4], C.G. Bell[6], J.A. Todd[3], B.O. Böhm[5], S. Beck[6], R.D. Leslie[1];
[1]Centre for Diabetes, Blizard Institute of Cell and Molecular Science, London, [2]Department of Genetics,, University of Cambridge, [3]Department of Medical Genetics, Department of Medical Genetics, Cambridge Institute for Medical Research, University of Cambridge, Addenbrooke's Hospital, London, [4]The Genome Centre, Queen Mary University of London, Barts and The London School of Medicine and Dent, London, United Kingdom, [5]Department of Internal Medicine I, University Medical Center Ulm and Center, University Medical Center Ulm, Germany, [6]UCL Cancer Institute, University College London, United Kingdom.

Background and aims: Type 1 diabetes (T1DM) is a complex multifactorial autoimmune disease caused by a combination of genetic and non-genetic factors. A role for the latter is suggested by studies of migrant populations, twin-cohorts, and the recent rise in T1DM prevalence. To assess whether epigenetic factors could contribute to these non-genetically determined effects we performed a genome-wide, promoter-specific DNA methylation analysis.
Materials and methods: We studied $CD14^+$ monocytes from 15 childhood-onset T1DM-discordant monozygotic (MZ) twin pairs, 9 control MZ twin pairs, plus 7 non-diabetic antibody-positive children studied prospectively before and after they developed T1DM. Methylation profiling was done using Illumina HumanMethylation27 BeadChips which allow for DNA methylation analysis of >27,000 CpG sites associated with >14,000 promoters per sample.
Results: We identified 132 T1D-associated methylation variable positions (T1D-MVPs) (P=0.02). Importantly, T1D-MVPs displayed statistically sig-

nificant trends for methylation differences in the expected direction in an independent set of T1DM singletons and controls, both before (P=0.001) and after (P=0.015) disease-onset, indicating epigenetic variation before T1DM clinical onset.
Conclusion: The identified T1DM-MVPs are associated with genes involved in pathways strongly implicated in the aetiopathogenesis of T1DM including major antigen expression, proinflammation, regulation of immunoglobulin secretion and apoptosis, with only a small over-representation of T1D-MVPs within known T1DM genetic susceptibility regions. Changes in DNA methylation in critical immune-response pathways probably contribute to the pathogenesis of T1DM.

A lipotoxicity model in the INS-1 832/13 beta cell line and the epigenetic alterations induced by it
S. Malmgren, V.V. Sharoyko, D.G. Nicholls, C.L.F. Nagorny, P. Spégel, M. Dekker Nitert, H. Mulder, C. Ling;
Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden.

Background and aims: The hallmarks of Type 2 Diabetes Mellitus (T2D) are peripheral insulin resistance that in combination with impaired insulin secretion results in hyperglucemia. While T2D has a strong genetic component, the disease can be triggered by obesity and a sedimentary lifestyle. Plasma free fatty acids (FFA) are elevated in obese subjects and this is believed to be an important pathogenic factor in T2D. Histone proteins and the nucleosomes they form with DNA are the fundamental building blocks of chromatin. Histone acetylation is a chromatin modification associated with an open chromatin structure and increased gene transcription. Histone acetyl transferases (HATs) and histone deacetyltransferases (HDACs) are enzymes which regulate histone acetylation. It has previously been demonstrated that the regulation of insulin expression by glucose is under the control of histone acetylation. The aim of our study is to examine whether a lipotoxic challenge of clonal 832/13 beta-cells induces epigenetic alterations and impaired metabolism.
Materials and methods: Insulin secretion for one hour in static incubation was measured by RIA. Differences in glucose metabolism were assessed by Extracellular flux analyzer XF24 (Seahorse Bioscience, Billerica, MA). HAT and HDAC activity was measured using a Nuclear/Cytosol Fractionation Kit (BioVision, Mountain View, CA) and HAT/HDAC colorometric assays (BioVision, Mountain View, CA).
Results: Lipotoxic conditions, assessed as 0,5 mM palmitate for 48 h, significantly increased basal secretion at 2,8 mM of glucose from 9 ±3 ng/mg/h to 29 ±6 ng/mg/h (p<0,001) and significantly decreased glucose-stimulated insulin secretion at 16,7 mM of glucose in beta-cells from 172 ±60 ng/mg/h to 52 ±15 ng/mg/h (p<0,05). In extracellular flux (XF) measurements lipotoxic beta-cells failed to increase oxygen consumption rates (OCR) in response to elevated glucose to the same extent as control cells. While 16,7 mM of Glucose increased OCR expressed as area under curve (AUC) with 32 ±0,02 % the same increase was only 12 ±0,03 % under lipotoxic conditions (p<0,05). This suggests that the lipotoxic beta-cells have a diminished ability to increase ATP production in response to increases in glucose concentration. HAT activity was elevated more than 4-fold in lipotoxic cells versus control cells (p<0.05), which suggests that elevated levels of FFA may induce epigenetic changes and gene transcription in the clonal 832/13 beta-cells. HDAC activity was not affected by lipotoxicity.
Conclusion: The lipotoxicity model we established affected glucose-stimulated insulin secretion in a way which mimics that seen in T2D patients. We can also conclude that part of this is due to metabolic effects such as lack of increased OCR, probably reflecting a decrease in ATP production. Finally, elevations in HAT activity indicate that lipotoxicity induces activation of genes in the clonal 832/13 beta-cells.

349

Smoking impairs glucose control in patients with type 1 diabetes mellitus: a prospective, longitudinal single-center study
P.A. Gerber, R.E. Locher, G.A. Spinas, R. Lehmann;
Endocrinology and Diabetes, University Hospital Zurich, Switzerland.

Background and aims: Smoking is known to negatively influence metabolic control in patients with type 1 diabetes mellitus. However, previous multicenter cross-sectional studies lack information on possible differences in diabetes therapy and consultation adherence between smokers and non-smokers. The aim of this prospective single-center study was to determine the effect of smoking on metabolic control during a longitudinal observation period.
Materials and methods: Patients with type 1 diabetes mellitus who were referred to our institution were included if written informed consent was given. Data on smoking habits and metabolic control (HbA_{1c}) were taken at baseline and during follow-up, as well as on insulin dosage, weight, blood pressure and serum lipids. All patients were seen every 3 to 4 month and treated with intensive insulin therapy or continuous subcutaneous insulin infusion.
Results: 763 patients were included, 160 (17.1%) were smokers. HbA_{1c} levels differed significantly between current smokers and non-smokers at baseline and during follow-up (mean 6.6 years, mean HbA_{1c} 7.9±1.3 vs 7.3±1.1%, p=0.001) (figure 1, **p<0.001, *p<0.05). There was no difference between smokers and non-smokers in terms of age (35.1±12.8 vs 36.1±14.2y), diabetes duration (11.5±10.8 vs 13.4±12.5y) and BMI (23.6±4.5 vs 23.9±5.8kg/m^2). However, there was a significant difference in gender between the two groups (71.3% male in smokers, 52.1% in non smokers). Therefore, every analysis comparing the two groups was adjusted for gender. At the end of follow-up, weight, blood pressure and serum lipids were not different between the two groups when adjusted for gender. The proportion of patients with two or more diabetes related complications was higher in smokers at the end of follow-up (p=0.04). Insulin requirement at the end of follow-up was higher in smokers than in non-smokers (0.71±0.30 vs 0.65±0.31IU/kg/d, p=0.04), whereas there was no difference in the occurrence of severe hypoglycemias (16 events per 100 patient years in smokers, 17 in non-smokers).
Conclusion: In conclusion, this study demonstrates that patients with type 1 diabetes mellitus who smoke have a significantly worse metabolic control than non-smokers despite the same quality and intensity of diabetes treatment.

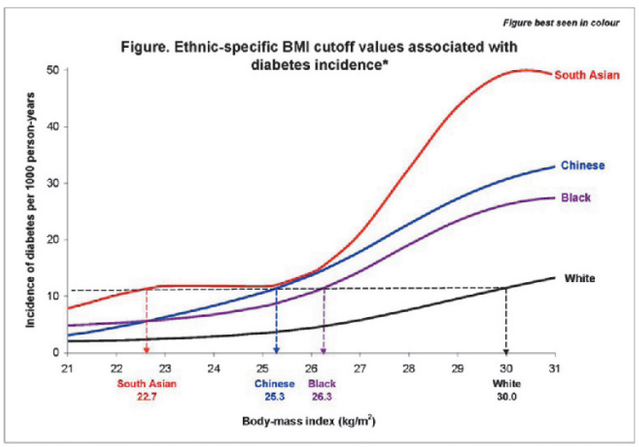
A comparison of diabetes incidence in Whites, South Asians, Chinese and Blacks: a population-based cohort study in Ontario, Canada

M. Chiu, P. Austin, D.G. Manuel, B.R. Shah, J. Tu;
Institute for Clinical Evaluative Sciences, Toronto, Canada.

Background and aims: Diabetes is a growing epidemic in many countries worldwide. While ethnic differences in the prevalence of diabetes is well documented, little is known about the relative *incidence* of diabetes across the world's four major racial-ethnic groups; Whites, Chinese, South Asians, and Blacks. We therefore conducted a population-based comparison of incidence rates of diabetes across Whites, Chinese, South Asians, and Blacks living in Ontario, Canada. We also derived ethnic-specific body-mass index (BMI) cutoff values to define obesity based on clinically-ascertained diabetes.
Materials and methods: We conducted a cohort study of 59824 non-diabetic adults (57210 Whites, 866 Chinese, 1001 South Asians, and 747 Blacks) aged 30 years or older, who were derived from Statistics Canada's population health surveys (1996-2005). Subjects were followed up for up to 12 years for diabetes incidence using record linkages to the Ontario Diabetes Database, an administrative-based algorithm shown to identify diabetes with 86% sensitivity and 97% specificity.
Findings: Diabetes incidence (per 1000 person-years) was highest among South Asians (20.8), followed by Blacks (16.3), Whites (9.5), and Chinese (9.3). Cox proportional hazards regression models adjusted for age, sex, BMI, and sociodemographic characteristics revealed hazard ratios (HR) that were significantly higher in South Asians (HR: 3.40), Blacks (HR: 1.99), and Chinese (HR: 1.87) than Whites (all p<0.0001). The median age at diagnosis was 9 years younger in South Asians and 3 years younger in Chinese than in Whites. Ethnic-specific BMI cutoff points for diabetes risk were identified using Poisson regression and restricted cubic splines. For the equivalent incidence rate of diabetes at BMI 30 kg/m^2 in Whites, the candidate BMI cut-off points were 23 kg/m^2, 25 kg/m^2, and 26 kg/m^2 for South Asians, Chinese, and Blacks, respectively (see Figure).
Interpretation: Current screening and prevention strategies for diabetes are informed mainly by studies of White populations; however, our study suggests that the risk of new diabetes is significantly greater in South Asians, Chinese, and Blacks; that these groups present with diabetes at younger ages; and that the current definition of obesity is inadequate for assessing diabetes risk in these non-White groups. Ethnic-specific prevention programs and equitable health services are needed to reduce the burden of diabetes in these high-risk populations.



*Association between body-mass index (BMI) and incidence of diabetes (per 1000 person-years), by racial-ethnic group, Ontario, Canada. Poisson regression and restricted cubic splines were applied; models were adjusted for age, sex, race-ethnicity, BMI, BMI-ethnicity interaction, age-BMI, income adequacy, survey year, and urban vs. rural dwelling.

The association between physical activity and type 2 diabetes according to weight status among different ethnic groups

W.M. Admiraal[1,2], I.G.M. van Valkengoed[2], J.S.L. de Munter[2], J.B.L. Hoekstra[1], K. Stronks[2], F. Holleman[1];
[1]Department of Internal Medicine, [2]Department of Social Medicine, Academic Medical Centre, Amsterdam, Netherlands.

Background and aims: Physical inactivity and adiposity are both independently related to type 2 diabetes (DM). Some studies have suggested that a high level of physical activity can counterbalance the negative health effects of obesity. This implies a differential effect of physical activity according to weight status. Moreover, effects of physical activity may potentially differ between ethnic groups. Therefore, we studied differences in the association between physical inactivity and DM according to weight status among individuals from different ethnic groups.
Materials and methods: We analysed data on 508 White Dutch, 596 African-Surinamese and 339 Hindustani Surinamese participants, aged 35-60 years, in the population-based, cross-sectional SUNSET study. Physical activity was measured using the Short Questionnaire to Assess Health-enhancing Physical Activity, which covers similar topics as the long-format International Physical Activity Questionnaire and has been validated for the Dutch population. Physical inactivity was defined as the lowest quartile of reported activity (min/week). Overweight was primarily defined as a BMI > 25 kg/m^2, and in a second analysis as a waist circumference ≥ 94 cm in men and ≥ 80 cm in women. DM was defined based on fasting plasma glucose levels and self-reported diagnosis of DM.
Results: Physical inactivity was independently associated with DM; after adjustment for sex, age, ethnicity and BMI, the odds of having diabetes was 1.69 (95% CI: 1.08-2.63) higher in individuals in the lowest quartile of physical activity, compared to those in the highest quartile. This association was present in both overweight individuals and those with a normal BMI, although this was only significant in overweight individuals (normal BMI: OR 1.51, 95% CI 0.60-3.75, overweight: OR 1.79, 95% CI 1.07-2.98). The association between physical inactivity and diabetes was stronger in ethnic Dutch, (OR 4.81, 95% CI 1.32-17.61) than in Hindustani Surinamese (OR 1.50, 95% CI 0.76-2.98) and African Surinamese (OR 1.40, 95% CI 0.70-2.81), after adjustment for sex, age and BMI. As also observed in the total population, weight status did not alter the association between physical activity and DM within the ethnic groups. Similar results were obtained when using waist circumference as an indicator of overweight.
Conclusion: Physical inactivity was independently associated with type 2 diabetes among both individuals with overweight and individuals with normal weight. This confirms the importance of regular exercise for all. However, the results suggest that potential health gain may differ between ethnic groups.

352

Risk factors associated with age at diagnosis of type 2 diabetes mellitus in a bi-ethnic population

A. Chetrit[1], K. Abu-Saad[1], H. Murad[2], F. Lubin[1], A. Ziv[3], G. Alpert[4], A. Atamna[4], O. Kalter-Leibovici[1,5];
[1]Cardiovascular Epidemiology, Gertner Institute, Ramat-Gan, [2]Biostatistics, Gertner Institute, Ramat-Gan, [3]Information and Computer, Gertner Institute, Ramat-Gan, [4]Shomron Administration, Clalit Health Services, Hadera, [5]Sackler Faculty of Medicine, Tel-Aviv University, Israel.

Background and aims: Ethnic minorities have higher prevalence of type-2 diabetes mellitus (T2DM) as compared to majority population groups. Younger age at diagnosis may further increase the burden of disease in ethnic minority groups. We explored factors associated with age at diagnosis of T2DM in the Arab minority and the Jewish majority groups in Israel.
Materials and methods: Participants (1,100; age: 25-74 years) were selected at random from the urban general population in the Hadera district in Israel. Information collected by interviews included socioeconomic status (SES) parameters, diabetes status, lifestyle habits (including dietary intake till T2DM diagnosis or interview), height, body weight during most of adult life, and history of diabetes in first degree relatives. Family history score of diabetes (T2DM FHScore) and dietary energy density (DED) in calories/grams were calculated. Factors associated with age at diagnosis of T2DM were tested using a multivariate Cox proportional hazard model.
Results: Of 1,093 participants with information on diabetes status, 180 had T2DM (16.5%). Arabs had higher prevalence of T2DM than Jews (21.0% vs. 12.0%; HR: 1.99 [95%CI: 1.47-2.71], P<0.01). The mean (SD) age at T2DM diagnosis was 52.2 (10.2) years in Arabs vs. 56.1 (10.8) in Jews; p=0.02. By the age of 57 years, 25% of the Arab participants had T2DM. The corresponding

age in the Jewish participants was 68 years (p<0.0001). In multivariate analysis, Arabs had 1.70 times greater risk for T2DM compared to Jews (95%CI: 1.19-2.43), adjusted for gender, BMI during most of adult life, T2DM FHScore and DED. Other factors associated with risk of T2DM included: higher BMI during most of adult life, higher T2DM FHScore, and higher DED (see table). SES parameters, cigarette smoking, gender, and current physical activity were not significantly associated with the risk for T2DM.
Conclusion: Compared to the Jewish majority group, people of the Arab minority group in Israel are at higher risk for having T2DM at a younger age, and greater loss of healthy life-years. Efforts to prevent or delay the onset of T2DM should be directed towards ethnic minority groups at high risk, in order to reduce diabetes-related health disparities.

Table: Factors associated with the risk for T2DM

Risk Factor*	Hazard Ratio (HR); 95% confidence interval (CI)
Ethnic group (Arabs vs. Jews)	1.70; 1.19-2.43
BMI during most of adult life (highest vs. tertile)	2.07; 1.34-3.21
T2DM FHScore (highest vs. lowest)	5.78; 3.99-8.36
DED (highest vs. lowest quartile)	1.67; 1.08-2.61

*-adjusted for gender

Ethnic-specific cut-points for central obesity measures for predicting insulin resistance in South African women

J. Evans[1], L. Micklesfield[1,2], C. Jennings[1], Y. Joffe[1], N.S. Levitt[1], E.V. Lambert[1], T. Olsson[3], J.H. Goedecke[1];
[1]University of Cape Town, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Umea University, Sweden.

Background and aims: The relationship between waist circumference (WC), visceral adipose tissue (VAT) and insulin resistance (IR) differs by ethnicity. The aim of the present study was to explore ethnic-specific cut-points for measures of central obesity for predicting IR as estimated by the homeostasis model (HOMA-IR) in black and white women, and to determine the optimal measure of central obesity i.e. WC vs. waist-height-ratio (WHtR) vs. VAT that best predicts IR in each ethnic group.
Materials and methods: Anthropometry (weight, height, WC, hip circumference), VAT (computed tomography) and HOMA-IR were measured in 241 black and 188 white premenopausal non-diabetic South African women, free from known disease and not on medication. IR was defined as the upper tertile of HOMA-IR for the whole group. The Youden index was calculated to determine the 'optimal' cut-point for WC, WHtR and VAT that best predicted IR. The accuracy of each measure to predict IR was assessed using receiver operator characteristic (ROC) curves.
Results: Ethnic-specific cut-points for central obesity measures for predicting IR are presented in Table 1.
Conclusion: In our population of apparently healthy black and white South African women, we show that measures of central obesity better predict IR in white than black women, but there is little difference between WC, WHtR and VAT in their ability to predict IR in both ethnicities. As we show that VAT adds no advantage in the prediction of risk, WC or WHtR, basic cost-effective anthropometrical measures, should be used to identify risk. Long-term prospective studies are required to examine whether individuals from these ethnic groups who exceed these cut-points develop cardiovascular disease and diabetes and/or whether these relationships are similar in groups with known disease or pathophysiology.

Table 1: Optimal WC, WHtR and VAT cut-points which best predict IR defined as HOMA-IR >2.09

	Black Women			White Women		
	ROC AUC ± SE	Cut-point	J value	ROC AUC ± SE	Cut-point	J value

The impact of migration on metabolic outcomes and coronary heart disease risk: a comparison of migrant South Asians, Asian Indians and white Europeans

J.J. Henson[1], L.J. Gray[2], K. Khunti[2], A. Guru[3], A. Misra[3], M.J. Davies[4];
[1]Diabetes Research, Leicester Royal Infirmary, [2]Health Sciences, University of Leicester, United Kingdom, [3]Department of Diabetes and Metabolic Diseases, Fortis Hospitals (Vasant Kunj and NOIDA), New Delhi, India, [4]Department of Cardiovascular Sciences, Leicester Royal Infirmary, United Kingdom.

Background and aims: Given the consistent findings of increased prevalence, premature onset and increased mortality from CHD in South Asian (SA) individuals, there is a need to determine the underlying causes in order to develop effective prevention and treatment strategies. One fifth of the developing world is represented by individuals of a SA origin and migration has resulted in large numbers of SAs settling in many developed countries. We investigated the impact of migration upon metabolic and CHD risk factors.
Materials and methods: This cohort consisted of 2287 White Europeans (WEs), 1007 SAs living in India (ISA) and 927 Migrant SAs (MSA) residing in the United Kingdom (UK). All subjects were aged 40-75 years. The WE and MSA cohort were recruited from a cross-sectional diabetes screening study conducted in Leicestershire, UK. ISA participants were recruited from a community-based epidemiological study, undertaken in Punjab, India. All participants underwent metabolic and anthropometric measurements. All those with established or newly diagnosed diabetes and CHD were excluded from analysis. Data is presented as mean ± SD or number (%). The MSA group were used as reference. P values were calculated using between groups ANOVA (*p<0.05, **p<0.001; see table 1). Non-parametric data were analysed using the Kruskal-Wallis test. χ^2 test was used for categorical data.
Results: MSAs had a significantly higher mean BMI and waist circumference for both males and females (p< 0.001) compared to ISAs; however, WEs had a significantly larger waist circumference than both Asian groups (see table 1). These relationships remained statistically significant after adjustment for age. MSAs had a significantly higher fasting plasma glucose compared to ISAs (p<0.05); furthermore, the prevalence of the metabolic syndrome (International Diabetes Federation criteria) was greater in MSAs compared to both ISAs (p<0.001) and WEs (p<0.05). MSA males had significantly higher cholesterol compared to ISAs (5.1mmol/L vs. 4.8mmol/L, p<0.05). In addition, MSA males had a significantly higher 10-year CHD risk (Framingham) compared to WEs (p<0.05); however, WE and ISA females had a significantly higher risk than MSAs (p<0.05).
Conclusion: This large dataset demonstrates that factors associated with migration serve to exacerbate some important indicators of cardiovascular and diabetes risk such as BMI, fasting glucose, serum cholesterol and waist circumference; however, certain modifiable risk factors, such as smoking were higher in ISAs females compared to MSAs, which contributed to a higher CHD risk in this group.

355

Levels of 25-OH-vitamin D in early pregnancy in women from five ethnic groups with and without gestational diabetes

L. Sletner[1,2], K. Mørkrid[1], B. Nakstad[2], K.I. Birkeland[1], A.K. Jenum[1];
[1]Dep. of Endocrinology, Oslo University Hospital, Aker, [2]Dep. of Pediatrics, Akershus University Hospital, Lørenskog, Norway.

Background: The STORK Groruddalen Research Program was set up to identify predictors for gestational diabetes (GDM) and foetal growth in a multiethnic population in Oslo. Inclusion will finish in May 2010. Poor vitamin D status has been linked to insulin resistance and in some studies it has been associated with GDM.
Aims: To assess levels of 25-OH-vit. D in early pregnancy in women from five ethnic groups who later developed GDM compared to women without GDM.
Methods: This is a population-based cohort study of pregnant women attending the Child Health Clinics in Groruddalen and their offspring. Information and questionnaires were translated to eight languages, covering the largest ethnic groups. Women were eligible if 1) living in the districts, 2) planned giving birth at the study hospitals, 3) in gestational week (GW) ≤20, 4) not suffering from diseases necessitating intensive hospital follow-up during pregnancy, 5) could communicate in Norwegian or any of the translated languages and 6) able to give informed consent. Ethnic origin in the present study: Europe (including North America), South Asia, East Asia, Middle East (including North Africa/Central Asia) and Somalia. Questionnaire data, blood pressure, anthropometric measurements, fasting blood and urine samples collected by midwifes were obtained at GW 10-20, 28 and 12 weeks postpartum. A 75 g OGTT was performed at GW 28 (24-32), glucose analyzed on site in venous EDTA blood samples (HemoCue, Angelholm, calibrated for plasma). The diagnosis of GDM was based on the WHO-criteria: fasting ≥7.0 or 2-hour value ≥7.8 mmol/l. 25-OH-vitamin D was measured by a radioimmunoassay method (DiaSorin, Stillwater, MN, USA). Descriptive analyses, ANOVA for continuous variables, chi-square tests for categorical variables and logistic regression analyses were performed.
Results: By March 1st 2010, 744 women were included (From Europe: 81.2% of the invited, Asia: 66.0%, Middle East: 64.5%, Africa: 60.3%). OGTT data were available from 539 women and 78 GDM cases (14.5%) were identified The crude prevalence of GDM was high in all groups (Europe: 12.7%, South Asia 13.4%, East Asia 24,0%, Middle East 22.4%, Somalia 18.5%)(Table 1). East Asian GDM women had a lower mean BMI than European GDM women ($p<0.05$). In women without GDM mean BMI was higher in the Middle East group than in Europeans ($p<0.05$). Odds ratio for GDM adjusted for age, parity, BMI and GW for minority groups from Asia and Africa compared to Europeans was 1.5-2.7, borderline significant for women from Middle East ($p=0.057$) and East Asia ($p=0.054$). 25-OH-vit. D was significantly lower in both GDM and non-GDM women from ethnic minorities compared to Norwegians, but no significant differences between GDM and non-GDM women were found.
Conclusion: The crude prevalence of GDM was high in all groups, but highest in groups from Asia and Africa. Low levels of 25-OH-vit.D was significantly associated with ethnicity, but not with GDM.

Trends in the prevalence of diabetes based on the level of education among Korean women: Korea National Health and Nutrition Examination Survey 1998-2007

J. Park[1], S.G. Kim[2], S.J. Yang[3];
[1]Inju University Sanggye Paik Hospital, Seoul, [2]Korea University Anam Hospital, Seoul, [3]Korea Univsersity Guro Hospital, Seoul, Republic of Korea.

Objective: This study was designed to determine the differences in the prevalence of diabetes based on the level of education in Korean women.
Research design and methods: A total of 3,842, 2,894, 3,020, and 1,647 women were included from The Korea National Health and Nutrition Examination Survey 1998, 2001, 2005, and 2007 surveys, respectively. Diabetes was defined as a self-reported history or a fasting plasma glucose ≥126 mg/dl. Education was classified into the following three categories: low (less than high school graduate), medium (less than college graduate), and high (college graduate or more). A linear model was used to test a trend of diabetes prevalence according to educational health inequality. A multiple logistic regression analysis was performed to estimate odds ratios for diabetes prevalence according to education levels.
Results: The prevalence of diabetes among Korean women was decreased from 8.1% in 1998 to 6.6% in 2007. Between these periods, there was a significant decreasing trend of the prevalence from 2.8% to 0.7% among women with a high education level, but no significant change was observed, such as from 12.2% to 15.3% among those with a low level of education ($p=0.002$ and $p=0.15$, respectively). A difference of diabetes prevalence between the high and low levels of education increased significantly across survey periods ($p=0.0007$). The odds ratio for the prevalence of diabetes in women with a low level of education compared to women with a high level of education increased from 1.6 in 1998 to 2.2 in 2001, 3.4 in 2005, and 4.8 in 2005 after adjusting for age, BMI, smoking, and exercise.
Conclusion: The prevalence of diabetes had an inverse relationship with the level of education in Korean women during last decade. More than the negative relationship, an educational health inequality for the prevalence of diabetes was widened during Korea's rapid economic development. Further studies on the causes of educational inequalities in the prevalence of diabetes, as well as the development of an effective intervention program, are imperative to reduce the prevalence of diabetes and a gap of the prevalence in Korean women.

Dairy consumption and insulin resistance syndrome: results from a French prospective study, D.E.S.I.R., data from the Epidemiological Study on the Insulin Resistance syndrome

F. Fumeron[1], A. Lamri[1], I. Porchay-Baldérelli[1], R. Jaziri[1], O. Lantieri[2], S. Vol[2], B.J. Balkau[3], M. Marre[1];
[1]INSERM U695, Paris, [2]IRSA, La Riche, [3]INSERM U1018, Villejuif, France.

Background and aims: In the French population from the D.E.S.I.R. cohort, cross-sectional analyses have shown that a higher consumption of dairy products or calcium is associated with a lower prevalence of the insulin resistance syndrome (IRS). The aim of our study was to assess the influence of dairy products on the nine year cumulative incidence of the IRS or associated diseases in this population-based prospective study with a 9-year follow-up, D.E.S.I.R..
Materials and methods: In total, 5212 volunteers from the western central part of France were included in the cohort. A questionnaire was completed by each participant at baseline, to determine the frequency and level of consumption of different foods. Two items concerned dairy products (cheese, milk and other dairy products). There were 4 groups according to the intake of dairy products (except cheese) and 3 groups for cheese intake. Calcium intake was calculated from the questionnaire. Calcium density of the diet was defined as the amount of calcium ingested per 1000kCal. Sex-specific calcium density quartiles were calculated. The associations between these dairy variables at inclusion and the incidence of metabolic diseases were tested using logistic regression models adjusted 1) for sex, age, alcohol, smoking, physical activity, fat intake and 2) the same covariates plus BMI. The odds ratios were determined by the logistic regression, indicating the risk for a change from one group to the next, e.g. from one quartile of calcium density to the next quartile. The association of dairy products with continuous variables was tested by analysis of covariance for repeated measures, using the same covariates as for the logistic regression.
Results: The consumption of dairy products other than cheese and calcium density of the diet were inversely associated with the incidence of the IRS and with the incidence of impaired fasting glycaemia (IFG) or type 2 diabetes (T2D) during the 9-year follow-up. The consumption of cheese was negatively associated with the incidence of the IRS, in particular after adjustment for BMI. (Table). These 3 parameters were associated with lower 9-year means of diastolic blood pressure, plasma triglycerides and insulin levels and with lower BMI gain in this period. Higher cheese intake and calcium density were associated with lower increase in waist circumference and plasma triglyceride levels. Dairy products and cheese intake were associated with a lower increase in blood pressure during the follow-up.
Conclusion: A higher consumption of dairy products and calcium reduces the incidence of the IRS during a 9-year period in a large cohort drawn from the French general population. This inverse association is observed with most of the traits of the metabolic syndrome. These results indicate that dairy product consumption could improve the cardiovascular risk.

High intake of fermented milk is associated with decreased risk of type 2 diabetes and better insulin sensitivity

E. Sonestedt, M. Orho-Melander;
Department of Clinical Sciences, Lund University, Malmö, Sweden.

Background and aims: Several observational studies have shown an inverse association between intake of dairy products and risk of type 2 diabetes (T2D). Fermented dairy products contain probiotic bacteria that may influence the composition of the gut microbiota, which are suggested to play a crucial role in the development of metabolic disorders; however, studies examining the association with fermented milk are lacking. We therefore explored the association between intake of specific dairy products (fermented milk, non-fermented milk, cheese (>10% fat), cream and butter) and incident T2D using the large Swedish Malmö Diet and Cancer study (MDCS) with comprehensive and detailed data on dairy food intakes. A genetic variant near the insulin receptor substrate 1 gene (*IRS1*) has been shown to associate with insulin resistance and T2D and we therefore wanted to examine if the associations between dairy intake and T2D differentiate depending on *IRS1* genotype.
Materials and methods: Among participants in the MDCS without a history of cardiovascular disease and diabetes (n=26,369; 44-74 y of age; 62% females), 1,616 individuals with incident T2D were identified from national and regional registers during a mean period of 12 y follow-up. Fasting blood glucose and plasma insulin were measured in 4,628 of the subjects at baseline, and HOMA index was used as a measure of insulin resistance. A total of 24,132 of the individuals were genotyped for the genetic variant in *IRS1* (rs2943641). Dietary data was collected using a modified diet history method. Cox proportional hazard regression was used to calculate hazard ratios (HR) for each energy-adjusted food group adjusted for several potential confounders (i.e. age, sex, energy intake, BMI, smoking habits, alcohol consumption, leisure-time physical activity, and education). In sensitivity analyses we excluded individuals reporting dietary change in the past as they are suspected to have unstable food habits. The interaction between *IRS1* genotype and food variables on incident T2D was assessed by introducing a multiplicative factor with continuous variables in the multivariate analyses.
Results: After adjusting for potential confounders, high intake of fermented milk was associated with lower HOMA index (*P*-trend=0.002), whereas high intakes of non-fermented milk and butter were associated with higher HOMA index (*P*-trend=0.0002 and 0.006, respectively). Without taking dietary change in the past into account, high intakes of cream, cheese and butter were associated with decreased risk of T2D (P-trend<0.05 for all). However, after excluding those 22% individuals reporting dietary change in the past, only high intake of fermented milk was significantly associated with decreased incidence of T2D (HR, 0.76; 95% CI, 0.64-0.91 for highest tertile of consumers vs. zero-consumers; *P*-trend=0.008). The C allele of rs2943641 was associated with insulin resistance assessed by the HOMA index (P=0.04) and T2D risk (OR, 1.13; 95% CI, 1.04-1.21). However, we observed no significant interaction between *IRS1* genotype and food variables on incident T2D.
Conclusion: This study indicates that intake of fermented milk is associated with better insulin sensitivity and that a high intake may reduce the risk of T2D. Our observation suggests that it is crucial to separate the effect of fermented and non-fermented milk products when investigating the health effect of dairy foods.

Alcohol consumption and the risk of developing prediabetes and type 2 diabetes in Swedish middle-aged men and women

M. Cullmann, A. Hilding, C.-G. Östenson;
Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Type 2 diabetes (T2D) has become a major health problem in many industrialized countries. Alcohol consumption represents a common and increasing habit in Sweden. It has been suggested as a potential, modifiable risk factor of T2D. However, more detailed information on effects of different types of alcoholic beverages as well as the effects on early phases of T2D development seems warranted. The aim of the present study was to investigate the influence of alcohol consumption and specific alcoholic beverages on the risk of developing prediabetes and T2D in Swedish middle-aged men and women.

Materials and methods: The data of 2004 men and 2961 women, aged 35-56 yrs at baseline, from the Stockholm Diabetes Prevention Program was evaluated in this cohort study. All subjects had normal glucose tolerance at baseline. Logistic regression analysis was performed to estimate the risk (expressed as odds ratio (OR) and 95% CI) to develop prediabetes and T2D at follow up, 8-10 yrs later, in relation to self reported, baseline alcohol intake (converted to g/day) derived from wine, beer, dessert wine and hard liquor. Adjustment was preformed for several life style factors.
Results: When adjusted for confounders, no significant association was found with total alcohol consumption and prediabetes or T2D in both men and women. However, men showed a higher risk for T2D when having a high liquor consumption (OR: 2.01 (95% CI: 1.10-3.65)) and a higher risk for prediabetes when drinking high amounts of beer (OR: 1.72 (1.06-2.81)) compared to occasional drinkers. Women showed a reduced risk for T2D in the medium liquor group (OR: 0.39 (0.17-0.91)) and a 2-fold higher risk for prediabetes in the high liquor group (OR: 2.37 (1.44-3.89)) but a reduced risk for prediabetes in the high wine intake group (OR: 0.65 (0.43-0.99)) compared to occasional drinkers.
Conclusion: This is the first study to investigate the possible risk of different alcoholic beverages on the development of prediabetes in women. Although no significant associations were found to total alcohol consumption in men and women, high consumption of hard liquor and beer increased the risk of T2D development. Since alcohol in some instances reduced the risk, it is possible that other factors than ethanol might play a role.

The inverse association between alcohol intake and complement C3 can be attributed to wine consumption and is explained by inflammation, HDL and insulin resistance, the CODAM study

M.M.J. van Greevenbroek[1], C.J.H. van der Kallen[1], I. Ferreira[2], E.E. Blaak[3], C.G. Schalkwijk[1], E.J.M. Feskens[4], C.D.A. Stehouwer[1];
[1]Internal Medicine (UNS 50 box 14), Maastricht University, [2]Internal Medicine / KEMTA, Maastricht University, [3]Human Biology, Maastricht University, [4]Wageningen University, Netherlands.

Background and aims: Moderate alcohol consumption has beneficial effects on CVD risk. Complement C3 is an early marker of insulin resistance and a risk factor for CVD and a negative association between alcohol consumption and circulating C3 has been reported. However, whether all sources of alcohol (e.g. wine, beer or other) are equally associated with C3 is not known. Also, the mechanisms that can explain any such inverse associations are not known. Beneficial effects of (moderate) alcohol consumption on inflammation, HDL and insulin resistance are likely candidates in this regard. The aim of this study was therefore to determine whether an inverse association between alcohol consumption and C3 is present and to investigate the extent to which this is (1) due to a specific source of alcohol and (2) explained by inflammation, HDL and/or insulin resistance.
Materials and methods: We investigated the Cohort on Diabetes and Atherosclerosis Maastricht (n=574, 61.3% men, 59.1 ± 7.0 yrs of age). Alcohol intake from different sources (beer, wine and others) was estimated by means of a validated food frequency questionnaire (FFQ). Subjects with unreliable FFQ (n=56) or who had missing data on the other variables (n=22) were excluded. First, we determined the association between alcohol consumption (total amount or from different sources, main determinant) and C3 (main outcome, standardized value) using linear regression (adjusted for age, sex, total energy intake, physical activity, waist, smoking, total cholesterol, ALAT, prior CVD, glucose tolerance status, use of medication). Next, we investigated whether this association could be attributed to a specific dietary source of alcohol. Lastly we investigated whether this association was (statistically) explained by inflammation (expressed as the average Z-score of CRP, IL6, SAA, sICAM, ceruloplasmin and haptoglobin), HDL-cholesterol and/or insulin resistance (as HOMA2ir).
Results: After adjustment for the above-mentioned covariates, alcohol consumption (in 10 g/d) was inversely associated with circulating C3; β [95% CI]; -0.057 [-0.100; -0.014] (p=0.010). When each source of alcohol was adjusted for each other and the covariates, only wine was independently associated with C3 (βs [95% CI] were -0.087 [-0.140; -0.033], p=0.002; -0.042 [-0.107; 0.023], p=0.222; -0.004 [-0.080; 0.072], p=0.908 for wine, beer and others, respectively). In the final analyses, we therefore focused on alcohol consumption from wine (in 10 g/d). The strength of the association between alcohol from wine and C3 was attenuated after further adjustments for inflammation (by 24.1%), HDL (by 33.3%), or HOMA2IR (by 36.8%), and was attenuated by 73.6% when these three mediators were added together.
Conclusion: The negative association between alcohol intake and circulating C3 can be mainly attributed to wine consumption and is largely explained by the favorable impact of alcohol consumption on inflammation, HDL and insulin resistance. This suggests that this association is more likely related to non-alcohol components of wine, than to the alcohol component itself.

Steatosis of donor's liver and its relationship to post-transplant diabetes mellitus in liver transplantation

M.X. Yu, X. Chen, J. Zhou, J. Gao, X. Gao;
Endocrinology, Zhongshan Hospital Affiliated to Fudan University, Shanghai, China.

Background and aims: Previous study indicated that HCV infection, immunosuppressant including steroid and calcineurin inhibitor, age over 45yrs, family history of DM, overweight, impaired glucose regulation before transplant, MCV infection, acute rejection(AR), cirrhosis especially decompensation cirrhosis et al were risk factors to post-transplant diabetes mellitus(PTDM). The relation between steatosis of donor's liver and PTDM was rarely reported. The aim of our study was to discuss steatosis of donor's liver and its relationship to post-transplant diabetes mellitus in liver transplantation.
Materials and methods: We retrospectively analyzed 438 patients who performed orthotopic liver transplantation (OLT) in our center between April, 2001 and December, 2008. Patients with history of using steroids, or data incomplete or died within 3 months after OLT were excluded. The grade of liver steatosis was taken pathological grading of non-alcoholic fatty liver disease (NAFLD), and fatty content less than 5% was considered without steatosis, otherwise was steatosis. Liver function was graded to A, B and C level according to Child-Pugh grade system. Patients were divided into PTDM and non-PTDM group according to fasting plasma glucose(FPG) after operation. Univariate analysis was used to analyze the possible risk factors, such as age, gender, family history of DM, HBV or HCV infection, FPG, BMI, liver function pre-operation, cirrhosis, steatosis of donor's liver, AR, immunosuppressive drugs, metabolite related risk factors, interleukin 2 receptor antagonist(IL-2RA). Multivariate logistic regression was used to analyze factors including age, FPG, HBV infection, cirrhosis, liver function pre-operation, steatosis of donor's liver, basic diseases before operation, IL-2RA, immunosuppressive drugs and AR. Student's t test (One-Way ANOVA) was used to compare quantitative variables and Chi-square test was used to compare qualitative variables. P value less then 0.05 was considered statistically significant. Statistic analysis was done by SAS 8.2 and SPSS 16.0.
Results: Among 438 patients, there were 298 non-PTDM and 140 PTDM patients. Among 298 non-PTDM patients, there were 103 steatosis of donor's liver, taking 34.6%, and 62 steatosis of donor's liver among 140 PTDM patients, taking 44.3%. Univariate analysis indicated that liver function and fasting plasma glucose pre-operation, the use of IL-2RA and calcineurin inhibitor were significantly related with PTDM (All P< 0.05), but steatosis of donor's liver was at the critical level (P=0.050). While multivariate logistic regression indicated that FPG pre-operation and steatosis of donor's liver had positive relationship with PTDM, their OR value was 1.853 (P<0.01) and 1.803 (P<0.05) respectively. And the use of IL-2RA was negatively related with PTDM with OR value of 0.427 (P<0.01).
Conclusion: We found that steatosis of donor's liver, abnormal fasting plasma glucose, liver function pre-operation and calcineurin inhibitor were risk factors of PTDM.

B12 deficiency is more common than folate deficiency in early pregnancy: do we need to consider B12 fortification?

P. Saravanan[1], C. Wood[2], N. Anderson[2];
[1]CSRI, Warwick Univ. & George Eliot Hospital, Coventry, [2]Biochemistry, George Eliot Hospital, Nuneaton, United Kingdom.

Background and aims: Foetal programming due to gene-diet interactions during the periconceptional period has been linked to increased risk of Type 2 diabetes mellitus (T2DM) and cardiovascular disease (CVD) in the offspring during their adult life. In addition, children who are born small but gain weight rapidly during the early years and become obese in adult life are particularly at risk of T2DM and CVD. A large prospective observational

study showed that offspring born to mothers with high folate and low B12 levels during mid-pregnancy, had the highest adiposity and greatest insulin resistance. In presence of such imbalance, it is plausible biochemically, excess energy is converted to adipogenesis as opposed to myogenesis. Though such imbalance is likely to be common in a mainly vegetarian population such as in India, recent evidence suggests that such phenomenon may not be uncommon in the UK adult population too. In animal studies, epigenetic alterations of DNA methylation by B12 and folate during the periconceptional period result in increased adiposity and metabolic risk in the offspring. In addition, methyl donor deficiency leads to dysfunction of the ghrelin system with dramatic effects on intrauterine growth. Because of fortification of various foods and the recommendation for periconceptional folic acid supplementation, folate deficiency has become rare. B12 deficiency has thus become a potentially major modifiable risk factor for metabolic disease as well as neural tube defects (NTDs). Indeed, in the presence of adequate folate, NTDs due to B12 deficiency have tripled. Thus, reducing the incidence of B12 deficiency by fortification / supplementation has the potential to reduce the risk of metabolic disease in adult life and the overall burden of metabolic disease world-wide.
To investigate the incidence of B12 deficiency in a Caucasian population during early pregnancy.
Materials and methods: 200 Maternal serum samples (mean age 27y) at 16-18 weeks gestation were analysed for B12 and folate levels using an electrochemiluminescence immunoassay. 200 samples from non-pregnant women of child-bearing age (mean 28y) were analysed as controls.
Results: B12 deficiency (<191ng/L) was common during pregnancy compared to age-matched control non-pregnant women (20% vs 4%, p=<0.0001). Folate deficiency was 6% and 13% in the pregnant and non-pregnant women respectively (<4.6μg/L). Significantly more pregnant women had folate levels above the reference range (>18.7μg/L), compared to the non-pregnant group (8% vs 3%, p=0.0283). This is likely due to increased folic acid intake during pregnancy. Median B12 levels are significantly lower (median: 262ng/L vs 363ng/L, p=<0.0001) at 16-18 weeks of pregnancy. This may be due to increased utilization during pregnancy, especially in the presence of higher folate levels.
Conclusion: These data indicate that B12 deficiency is common in early pregnancy even in a non-vegetarian UK population. If untreated, such deficiency may get worse in later pregnancy, potentially increasing the risk of metabolic disorders such as T2D and CVD. Given recent evidence linking B12 deficiency to NTDs, our findings suggest in addition to folic acid, B12 fortification should be considered. Intervention studies of B12 supplementation in early pregnancy and their effects on offspring are urgently needed. In addition, further studies designed to identify the potential mechanisms are warranted.

PS 13 Screening and prediction of type 2 diabetes mellitus

Comparison of American Diabetes Association and World Health Organisation indications for performing oral glucose tolerance test
P. Tzoulis[1], E. Denver[1], N. James[2], M. Barnard[1];
[1]Department of Diabetes, [2]Department of Biochemistry, The Whittington Hospital NHS Trust, London, United Kingdom.

Background and aims: There is a discrepancy between American Diabetes Association (ADA) and World Health Organisation (WHO) cut-off values of fasting plasma glucose (FPG) for diagnosing Impaired Fasting Glycaemia (IFG). ADA recommends an FPG cut-point for IFG of 100 mg/dl (5.6 mmol/l). WHO and the European Diabetes Epidemiology Group recommend the cut-point of 110 mg/dl (6.1 mmol/l). The aim of this study is to determine which FPG cut-point should be used when deciding whether to perform an Oral Glucose Tolerance Test (OGTT). It also aims to assess the impact of age, gender and ethnic origin on the relationship between FPG and 2-h plasma glucose (2-h PG).
Materials and methods: Our hospital serves an inner city area in London with a multiethnic population of over 250,000 people. We conducted a retrospective analysis of OGTTs performed in our institution over a 24-month period from 1st May 2006 to 30th April 2008.
Results: Data was collected on 1598 patients (mean age 58.7 years ± 13.5 years, 54.2% males and 45.8% females). Amongst the subjects there were 44.7% White, 9.9% Black, 6.2% Asian and 39.2% cases of 'other ethnic origin' or 'not stated'. Among participants with FPG of 100-109 mg/dl (normal according to WHO, but IFG according to ADA) 34.1% had impaired glucose tolerance (IGT) and 11.8% had diabetes based on 2-h PG (overall 45.9% impaired glucose regulation). In those with FPG of 110-125 mg/dl (IFG according to both ADA and WHO), 39.0% had IGT and 29.0% diabetes based on 2-h PG (overall 68.0% impaired glucose regulation). In those with FPG of <100 mg/dl (normal according to ADA and WHO), 19.3% had IGT and 4.6% diabetes based on 2-h PG (23.9% impaired glucose regulation). A statistically significant association was found between FPG and 2-h PG (p<0.001) and a positive linear relationship between FPG and 2-h PG was observed (correlation coefficient 0.436). For participants with FPG of 100-109 mg/dl, a statistically significant relationship between different age groups and 2-h PG was demonstrated (p=0.012). The proportion of participants with FPG of 100-109 mg/dl who had IGT showed a steady increase: 26.7% among <50 years of age, 29.6% among 50-60 years , 38.7% among 60-70 years , 42.4% among >70 years of age. A similar trend was noted in the proportion of individuals who were diagnosed with diabetes based on 2-h PG. For subjects with FPG of 100-109 mg/dl, no statistically significant association was noted between gender or ethnic origin and 2-h PG.
Conclusion: In this study, by applying a WHO cut-point for FPG of 110 mg/dl (6.1 mmol/l) we would have missed the diagnosis of impaired glucose regulation in a large proportion of subjects. A significant proportion of our population with FPG of 100-109 mg/dl had IGT (34.1%) or diabetes (11.8%) based on 2-h PG. This may reflect the characteristics of our local population and further studies should guide whether OGTT is indicated in individuals with FPG of 100-109 mg/dl.

Distribution of subjects by fasting and 2-h plasma glucose

FPG	<140 mg/dl(normal)	140-199 mg/dl (IGT)	≥ 200 mg/dl (diabetes)
<100 mg/dl	347 (76.1%)	88 (19.3%)	21 (4.6%)
100-109 mg/dl	219 (54.1%)	138 (34.1%)	48 (11.8%)
110-125 mg/dl	148 (32.0%)	180 (39.0%)	134 (29.0%)
≥ 126 mg/dl	24 (8.7%)	56 (20.4%)	195 (70.9%)

364

Elevated one-hour post-load plasma glucose levels identifies subjects with normal glucose tolerance and impaired beta cell function, insulin-resistance and worse cardiovascular risk profile, the GENFIEV study

C. Bianchi[1], R. Miccoli[1], R.C. Bonadonna[2], G. Penno[1], G.A. Daniele[1], S. Politi[1], A. Agostini[1], S. Del Prato[1], on behalf of the GENFIEV Study Group; [1]Endocrinology and Metabolism, University of Pisa and Azienda Universitaria Ospedaliera Pisana, [2]Biomedical and Surgical Sciences, University of Verona, Italy.

Background and aims: Recent evidence suggests that in subjects with normal glucose tolerance (NGT) one-hour post-load plasma glucose (1h-OGTT glucose) >155 mg/dl may predict type 2 diabetes (T2DM) and is associated with subclinical atherosclerosis. This study evaluates beta-cell function, insulin-sensitivity and cardiovascular risk profile of NGT subjects with 1h-OGTT glucose >155 mg/dl.
Materials and methods: In 929 subjects, participating in to the GENFIEV (Genetic and Pathophysiology of Type 2 Diabetes Evolution) study, we performed an OGTT with measurement of C-peptide and fasting insulin. Insulin resistance was assessed by HOMA-IR, while beta-cell function was estimated by the Insulinogenic Index and minimal model analysis of plasma glucose and C-peptide response to a 2-hr 75-g OGTT.
Results: Based on the OGTT results, 51% had NGT, 4% IFG, 24% IGT, 7% both IFG and IGT, and 14% were diagnosed with new T2DM. Thirty-nine percent among NGT, 76% of IFG, 90% of IGT, 99% of IFG+IGT and 98% of newly diagnosed T2DM had 1h-OGTT glucose >155 mg/dl. This cutoff point has an high specificity (89%), a good sensibility (69%) and an high positive predictive power (92%) in identifying subjects with IGR or newly diagnosed T2DM. Among subjects with NGT (n. 474, 37% men and 63% women; age: 46±12 years, BMI: 28.4±5.3 kg/m2), those with 1h-OGTT glucose >155 mg/dl, were more insulin-resistant (HOMA-IR 2.7±1.9 vs 2.1±1.2 mmol/L x μU/ml; p<0.01) and had impaired first phase insulin secretion (Insulinogenic Index: 0.052±0.030 vs 0.092±0.17; p<0.01; C-CD: 1381±865 vs 1721±1384 Pmol/m2BSA/mM/min; p<0.005) and beta-cell performance (Disposition Index: 0.055±0.097 vs 0.026±0.025; p<0.001) compared to those with 1h-OGTT glucose ≤155 mg/dl. Moreover, HbA1c (5.6±0.4 vs 5.3±0.4%; p<0.0001), blood pressure (systolic: 128±13 vs 122±14 mmHg; p<0.0001 and diastolic: 81±10 vs 77±11 mmHg; p<0.0001), LDL-cholesterol (136±41 vs 127±37 mg/dl; p<0.05) and triglycerides (136±96 vs 117±75 mg/dl; p155 mg/dl, while HDL-cholesterol was lower (52±14 vs 56±16 mg/dl; p155 mg/dl had a similar cardiovascular risk profile, a comparable insulin-sensitivity impairment and a slightly better beta-cell function.
Conclusion: 1h-OGTT glucose >155 mg/dl shows a good performance in discriminating subjects with IGR/newly diagnosed T2DM and may identify, among NGT individuals, those with lower insulin-sensitivity, impaired beta-cell function and worse cardiovascular risk profile, i.e. those subjects at higher risk of developing T2DM and cardiovascular disease.

New and old criteria for the diagnosis of diabetes mellitus in patients with coronary artery disease

P. Rein[1,2], C.H. Saely[1,2], A. Vonbank[1,2], C. Boehnel[1,2], V. Jankovic[1,2], J. Breuss[1,2], S. Beer[1,2], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Recently, an International Expert Committee concluded that haemoglobin A1c (hba1c) may be a better means of diagnosing diabetes than glucose levels. A diagnosis of diabetes was recommended with hba1c ≥6.5%. Data on the concordance of new and old criteria for the diagnosis of diabetes are very scarce; no data at all are available for patients with coronary artery disease (CAD). We therefore aimed at investigating the concordance of new and old diabetes criteria in a large cohort of patients with angiographically proven CAD.
Materials and methods: We consecutively enrolled 1124 Caucasian patients with angiographically proven CAD who did not have previously known diabetes. An oral glucose tolerance test (oGTT) was performed in all patients.
Results: From the patients with diabetes according to the new diagnostic criterion hba1c ≥6.5% (n=110), 58 (53%) fulfilled the WHO glucose criteria for diabetes, 13 (12%) had impaired glucose tolerance (IGT), 26 (24%) impaired fasting glucose (IFG), and 13 (12%) normal fasting glucose (NFG). Conversely, the hba1c ≥6.5% criterion was fulfilled in 58 patients (63%) with diabetes according to WHO criteria, in 13 patients (11%) with IGT, in 26 patients (8%) with IFG, and in 13 patients (2%) with NFG. Compared to the standard of WHO criteria, the proposed hba1c ≥6.5% for the diagnosis of diabetes had a sensitivity of 63% and a positive predictive value of 53% for detecting previously undiagnosed diabetes, whereas specificity and negative predictive value were 95% and 97%, respectively.
Conclusion: The recently recommended hba1c criterion for the diagnosis of diabetes among CAD patients is highly specific but not sensitive. This might strongly limit its use as a screening tool for identifying individuals with diabetes.

Prevalence of diabetes mellitus after pregnancy with gestational diabetes mellitus using different cut-off criteria for abnormal glucose tolerance

E. Anderberg[1], M. Landin-Olsson[2], J. Kalén[3], A. Frid[4], D. Ursing[2], K. Berntorp[4];
[1]Obstetrics and gynecology, University of Lund, Lund, [2]Endocrinology and Diabetoplogy, University of Lund, Lund, [3]Internal Medicine, University of Lund, Lund, [4]Endocrinology Malmö, University of Lund, Lund, Sweden.

Background and aims: Gestational diabetes mellitus (GDM) is diagnosed using an oral glucose tolerance test (OGTT) but there is no consensus on diagnostic criteria. GDM is a reliably predictor for subsequent diabetes mellitus but more knowledge on the relationship between the OGTT result and future diabetes is needed. The aim was to determine the incidence of diabetes after GDM as defined by WHO 1999 using different cut-off levels for abnormal glucose tolerance during pregnancy.
Materials and methods: Women undergoing a 75 g oral OGTT during pregnancy and delivering during 2003-2005 were invited to a 5-year follow-up program postpartum. At first check-up, 1-2 years after delivery, 160 women with GDM, 309 with gestational impaired glucose tolerance (GIGT) and 167 controls with gestational normal glucose tolerance underwent an OGTT. Cut-off levels defining GDM and GIGT were 2-h capillary blood glucose levels of 9.0 and 7.8 mmol/l or plasma glucose 10.0 and 8.6 mmol/l.
Results: In addition to 15 women with GDM and 2 with GIGT diagnosed with diabetes before follow-up, 11% of women with GDM and 4% of women with GIGT were diagnosed as having diabetes, implying diabetes in 6% in the combined group. The corresponding figures for impaired glucose tolerance (IGT) were 23% and 24%. No one in the control group had diabetes whereas 10 % had IGT. Due to the low reproducibility of the OGTT women with GIGT were retested within one week, following which 24% were reclassified as having GDM, 43% with GIGT and 33% with GNGT with corresponding diabetes prevalence at follow-up of 13%, 4% and 0%.
Conclusion: Lowering the cut-off level for GDM to that proposed by WHO 1999 would substantially increase the number of women identified during pregnancy and thereby committed to special care during pregnancy and to follow-up postpartum. Lowering the threshold would dilute the diabetes prevalence and does not seem optimal to identify those at the highest risk of diabetes development. Retesting the GIGT group might offer a possible way to identify those in most need of medical attendance.

Usual delay in sample processing can underestimate detection of prediabetes and diabetes in Korea

J. Kang[1], C. Kim[1], S. Lee[1], S.-H. Ihm[1], M. Choi[2], H.-J. Yoo[3], C.-Y. Park[4], S. Park[4];
[1]Hallym University Sacred Heart Hospital, Gyeonggi-do, [2]Chuncheon Sacred Heart Hospital, Gangwon-do, [3]Hangang Sacred Heart Hospital, Seoul, [4]Endocrinology and Metabolism, Kangbuk Samsung Hospital, Seoul, Republic of Korea.

Background and aims: Diabetes has emerged as a public health issue worldwide, particularly in East Asia including Korea and consensus statements recommended early detection and preventive treatment in high-risk individuals. For detection of prediabetes and diabetes(hyperglycemic state), fasting plasma glucose (FPG) alone is commonly used as a screening test but serum should not be used, because the glucose concentration decreases 5~7% per hour as a result of erythrocyte glycolysis or slow serum/plasma separation. However, since serum glucose is commonly used as screening test in Korea. The purpose of this study was to assess whether ordinary delay in sample processing influences screening results of hyperglycemic state.
Materials and methods: Between 2007 and 2009, study subjects were recruited in 2028 Korean who visited the division of endocrinology for the evaluation of the IFG previously diagnosed with the serum glucose in the health examination. We make a comparison of difference between fasting serum glucose and fasting plasma glucose, measured at the same times, and evaluated the classification of glucose tolerance determined by a 75g oral glucose tolerance test (OGTT). We also make a comparison of laboratory findings between normoglycemia and diabetes, diagnosed with plasma glucose in study populations with normoglycemia in routine chemistry. We conducted a cross-sectional study, which was approved by the Institutional Review Board of the University Hospital.
Results: We firstly obtained blood samples from another 30 adults and serum glucose concentrations were measured immediately and after 0.5, 1, 1.5, 2, 2.5and 3 hr. All the specimens were kept at room temperature during this preliminary test. The concentration of glucose declined with time (118.9mg/dL, 114.4mg/dL, 111.9mg/dL, 109.7mg/dL, 107.1mg/dL, 105.8mg/dL and 102.6mg/dL at each times) and the main decrease occurred during the first 30 min. Among 1428 persons, we recruited 1254 subjects who were diagnosed with normal fasting glucose or IFG using FPG. Mean glucose concentrations were 117.4 ± 11.3 mg/dL in plasma and 106.8 ± 8.1mg/dL using routine chemistry (mean difference: 10.6 ± 2.5 mg/dL). Of 1061 subjects diagnosed with IFG using serum glucose, 235 (22.1%) were newly diagnosed with diabetes in fasting plasma glucose and 306 (28.8%) in 75g OGTT. Age, c-peptide and insulin level at 30minutes for 75g OGTT, AST and metabolic syndrome (%) showed significant differences between normoglycemia and diabetes diagnosed with plasma glucose in 169 subjects with normoglycemia in routine chemistry.
Conclusion: This study evaluated that the ordinary delay in sample processing influences diagnosis of hyperglycemic state and our results showed that this delay can underestimate detection of hyperglycemic state, in Korea. For the screening of prediabetes and diabetes, glucose level should be measured in plasma or within 30 minutes from venous sampling.

Increasing the flexibility of a screening model for incident diabetes only increases the predictive power marginally

D. Vistisen, A. Heraclides, K. Borch-Johnsen, D.R. Witte;
Steno Diabetes Center A/S, Gentofte, Denmark.

Background and aims: Risk scores for predicting diabetes tend to be simple and highly dependent on age. As such, they have limited use as a first step in a screening programme. The aim of this study was to derive a screening model based on established risk factor information obtainable through a mailed questionnaire but with a more flexible structure which accommodates the fact that some risk factors for diabetes may have different impacts in different sub-groups of people.
Materials and methods: The analysis is based on a Danish population-based primary prevention study, the Inter99 study. A total of 4,363 participants, free of diabetes at baseline and with 5-year follow-up data on diabetes status were analysed. All participants had complete information on age, sex, BMI, waist circumference, the use of antihypertensive- or lipid lowering treatment, family disposition to diabetes, smoking and physical activity. Glucose tolerance status at baseline was based on OGTTs. Incident diabetes was based on self-reported diabetes or OGTTs at follow-up examination. Two alternative screening models for incident diabetes were derived. A standard risk score assessed by Poisson regression analysis (risk score) and a more flexible model identified through tree-structured regression analysis (decision tree). The performance of the models was compared by ROC analysis.
Results: The standard risk score included information on age, sex, BMI, the use of antihypertensive- and lipid lowering treatment, parents with diabetes, smoking and leisure-time physical activity. The AUC of the standard risk score was 0.78 (95%-CI: 0.74-0.82). The decision tree included the same information as the standard model with the additional inclusion of waist circumference and had an AUC of 0.79 (95%-CI: 0.75-0.82).
Conclusion: A screening model allowing for a more flexible structure only increased the performance marginally.

Value of the FINDRISC questionnaire to identify prediabetes in a middle sized town in Sweden

M.I. Hellgren[1], P. Friberg[1], M. Petzold[2], C. Björkelund[1], H. Wedel[2], P.-A. Jansson[3], U. Lindblad[1];
[1]Department of Public Health and Community Medicine/Primary Health Care, University of Gothenburg, [2]Nordiska Högskolan för Hälsovetenskap, [3]Dep of Molecular and Clinical Medicin, University of Gothenburg, Göteborg, Sweden.

Background: Diabetes is a common disease in the western world today, particularly in Sweden and in Finland where the prevalence of the population between 45-75 years is about 5% and 5-10%, respectively. Type 2 diabetes (T2D) is preceded by a pre-diabetic state with either impaired fasting glucose (IFG) or impaired glucose tolerance (IGT). In this state, which may last for many years, several studies have shown that diabetes can be prevented. A combination of improved diet and increased physical activity is recognized as an efficient means to prevent development of overt T2D in subjects with IGT, but is not proved to be efficient in subjects with prediabetes/IFG. Identification of subjects with IGT is therefore of utmost importance in the strategy to prevent T2D. A questionnaire, FINDRISC, the Finnish Diabetes Risk Score, is developed and validated in Finland to identify subjects with increased risk of abnormal glucose tolerance (AGT =IFG/IGT/T2D). FINDRISC has never been evaluated in a Swedish population and is not validated to identify individuals with IGT.
Aim: To evaluate the FINDRISC questionnaire as a screening tool for diabetes and prediabetes (AGT) in an ordinary Swedish middle-aged and elderly population. In particular we wanted to identify individuals with IGT.
Materials and methods: The FINDRISC questionnaire was sent to a complete population of 5157 people, 35 to 75 years old, in a defined area in Skövde, a middle sized town of 50,000 inhabitants in the Western part of Sweden. All recipients were asked to return the completed questionnaire to the Primary

Health Care Centre at Hentorp. Maximum score was 26 and all with a self-calculated score ≥15 were encouraged to report to the clinic to have their fasting blood glucose tested. Those without diabetes were then tested with oral glucose tolerance test (OGTT) twice and participants were categorized as normal glucose tolerance (NGT), IFG, IGT, or T2D, respectively. Those with a mean 2h glucose showing IGT were invited to a diabetes prevention program.

Results: Research is ongoing and till now 2,618 questionnaires have been returned (50,7%). Mean age was 56±11 years in women and 58±12 years in men and mean score was 8.5±5.1 in men and 8.4±4.5 in women. Of these, 260 individuals (9.9%) had a risk score ≥15 and altogether 153 have, so far, had a fasting blood glucose test taken at the health care unit. We detected 16 subjects with new T2D (10.4%), 15 with IGT (9.8%) and 47 with IFG (30.7%). A FINDRISK score ≥15 was associated with a positive predictive value (PPV) of 51% for AGT, and a PPV of 9.8% for IGT.

Conclusion: In this first Swedish study the FINDRISC questionnaire was found to have a relatively high PPV of 51% when screening for AGT, but for IGT a PPV of only 9.8% was found. IFG was by far the most common form of abnormal glucose metabolism and preventive measures for these individuals should be better defined.

A Chinese diabetes risk score for opportunistic screening of undiagnosed diabetes and abnormal glucose tolerance

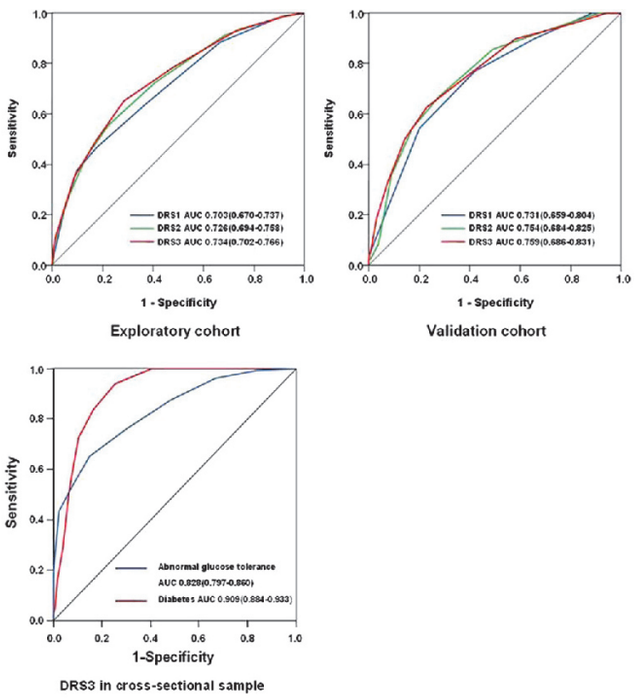
M. Liu[1], M. Jin[2], C. Pan[3];
[1]Endocrinology, The First Hospital Affiliated to Chinese PLA General Hospital, [2]Endocrinology, Peking University First Hospital, [3]Endocrinology, Chinese PLA General Hospital, Beijing, China.

Background and aims: To develop a diabetes risk score (DRS) to predict incident diabetes and evaluate its efficiency on screening for individuals at high risk for undiagnosed diabetes and abnormal glucose tolerance in Chinese population.

Materials and methods: Three DRSs were developed based on a 10-year follow-up cohort of 1,457 individuals aged 48-87 years without diabetes at baseline and validated on another cohort of 394 non-diabetes individuals age 43-88 years, followed up after 10 years. DRS1 contained simple clinical information, while DRS2 added fasting plasma glucose based on DRS1, and DRS3 added serum lipids based on DRS2. The DRS with the largest area under the ROC curve (AUC) was chose as the final DRS and was evaluated on screening of glucose abnormality in a cross-sectional sample of 699 individuals without known diabetes.

Results: DRS3 was considered as the final DRS because it had the best prediction property. AUC was 0.734 (95% CI 0.702-0.766) predicting diabetes within 10 years, and also had adequate performance in validation cohort (AUC=0.759 (0.686-0.831). The DRS3 had sensitivity of 64.5% and 72.9%, specificity of 71.6% and 63.9% with an optimal cutoff of 4 of 12. In the cross-sectional sample, AUCs were respectively 0.828 (0.797-0.860) and 0.909 (0.884-0.933) detecting abnormal glucose tolerance and diabetes. A two-step strategy, identifying individual at increased risk for diabetes using DRS3 as a first step, followed by OGTT performance led to the identification of 76.2% of case of abnormal glucose tolerance and 100% of cases of unknown diabetes, whereas only requiring an OGTT in 47.2% study group.

Conclusion: The diabetes risk score, including clinical information and biochemical indexes has good predictive ability for incident diabetes and is practical to screen subjects with abnormal glucose tolerance and diabetes in the general Chinese population.



ROC curves showing three DRSs predicting incident diabetes in both cohorts and DRS3 screening abnormal glucose tolerance and diabetes in cross-sectional sample

Low self rated health is associated with impaired glucose tolerance in men

B. Daka[1], C.A. Larsson[2], L. Bennet[2], L. Råstam[2], U. Lindblad[1];
[1]Department of Public Health and Community Medicine, The Sahlgrenska Academy, University of Gothenburg, [2]Lund University, Department of Clinical Sciences, Malmö, Sweden.

Background and aims: Self-rated health (SRH) is an independent predictor of future mortality. Recently, the weight gain in women seems to be influenced by previous poor SRH. Poor SRH in diabetics has been related with increased mortality according to McEwen et al. We attempt to see how poor SRH is related to IGT in subjects who are not aware of having it, in a Swedish population.

Materials and methods: This investigation is based on data from a population-based study in Vara(1811) and Skövde(1005) including subjects aged 30-74 years (1416 women and 1400 men) in two small communities in a rural area of south-western Sweden, as part of the Skaraborg Project. SRH was investigated by the question: "How do you rate your current health status in general?" with reply alternatives very good, good, reasonable, bad and very bad (called SRH-5 in the following text). Only a few participants rated their own health bad and very bad (fig 1). The variable SRH-5 was dichotomised in 2 values: High-SRH if the answer was "very good" and "good" and Low-SRH if the answer was "reasonable", "bad" and "very bad". A standard 75g oral glucose tolerance test (OGTT) was performed in each participant without known diabetes. Blood samples at fasting, 10, 30, 60 and 120 minutes after glucose administration were collected and analysed for p-glucose and s-insulin. IFG, IGT and diabetes was defined concordant with WHO criteria. HOMA-IR was calculated by formula HOMA-IR= FPG X FP insulin/22.5. Subjects with diabetes (108) were excluded from our analysis. Average weekly alcohol consumption, physical activities (PA) and sleeping disorders were estimated in a structured questionnaire. Logistic regression analysis has been used on estimating dichotomised variables and Univariate Analysis of Variance was used to estimate mean differences for continuous variables in subjects with low respective high SRH. Results were calculated separately in men and women.

Results: According to criteria described on methods 72.6 % rated high his own health and 26.3 % low (in 30/2816=1.1% missing). An evaluation av mean differences between subjects with low respective high SRH showed that low SRH is associated with higher BMI, fasting glucose, fasting insulin and HOMA-IR. Low SRH was also associated with higher incidence of IGT(M:

5.2% resp 13.4% Or 2,83 CI 1.8-4.4 p<0,001; F 8.5% resp 12.4% Or 1.52 CI 1,0-2.2 p=0.033). Adjusting for possible confounders age, BMI, PA, alcohol consumption and sleeping disorders we found a remaining strong association between SRH and IGT in males but not in females (Tab.1).
Conclusion: These results confirm IGT to influence independently the perception of health even when it is an unknown state. Nevertheless there are some gender differences suggesting ulterior confounders in men, in addition to those we reported. On the other hand SRH is confirmed an independent risk factor to disease which confirm the importance of using it on daily practice.

Tab 1. Logistic regression analysis adjusted for possible confounders in males.

Males	High SRH	Low SRH	OR/Δ mean	CI	P-value	P-value
IGT	5.2%	13.4%	2,83	**1.8-4.4**	**0.000**	**0.000**

Predictors of normalisation of prediabetes and of persistence of normal glucose tolerance: KORA S4/F4 cohort study
B. Kowall[1], W. Rathmann[1], M. Heier[2], R. Holle[2], A. Peters[2], B. Thorand[2], C. Herder[1], K. Strassburger[1], G. Giani[1], C. Meisinger[2];
[1]German Diabetes Center, Düsseldorf, [2]Helmholtz Zentrum München, Germany.

Background and aims: Reversion from prediabetes to normal glucose tolerance (NGT) without specific interventions has been rarely studied. We investigated in a cohort study which factors beyond blood glucose (lifestyle, clinical parameters) are associated with normalization of glucose tolerance. In addition, we investigated which factors contribute to long-term persistence of NGT.
Materials and methods: Oral glucose tolerance tests were conducted at baseline and at follow-up in a population-based study in Southern Germany (KORA S4/F4; 1,223 non-diabetic subjects aged 55-74 years at baseline (1999-2001); 887 subjects (73%), 436 of whom had prediabetes at baseline, participated in the 7-year follow-up). Prediabetes comprised impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) (ADA diagnostic criteria). Subjects who were prediabetic at baseline and normoglycaemic at follow-up were only classified as "return to NGT" when their fasting plasma glucose decreased by > 5 mg/dl or when their 2 h glucose decreased by > 10 mg/dl (clinically relevant differences).
Results: 66 of 436 (15%) subjects who had been prediabetic at baseline returned to NGT after 7 years. In a logistic regression model with age, sex, BMI, change of BMI, glucose values, diabetes family history, and lifestyle factors as independent variables, fasting and 2h glucose were strong predictors of normalization of prediabetes (p<0.001 both). Women were more likely to return to NGT (OR=2.6, 95%-confidence interval (CI)=1.3-5.0). A decrease in BMI significantly improved the chance of returning to NGT (OR, 95%CI: 7.7, 3.0-20.1 for BMI change <= -1kg/m^2, and 3.6, 1.6-8.2 for -1kg/m^2 < BMI change <= 1kg/m^2, compared to BMI change > 1kg/m^2) whereas baseline BMI was not independently associated with return to NGT (p=0.57). Physical activity, smoking and alcohol intake were not significantly associated with return to NGT. After replacing BMI by waist circumference (WC), an increase in WC turned out to diminish chances of return to NGT (OR: 0.7, 0.5-0.9 per 5 cm). Moreover, subjects with hypertriglyceridaemia (triglycerides >= 2.0 mmol/l) and subjects with low HDL-cholesterol (men: <= 1.03 mmol/l, women: <= 1.29 mmol/l) were less likely to become normoglycaemic (p<0.05). Among 451 subjects with NGT (baseline) 321 (71%) remained normoglycaemic in the 7-year follow-up. In a logistic regression model with age, sex, BMI, glucose values, family history, and lifestyle factors as independent variables, higher levels of 2h glucose (p<0.001), higher BMI at baseline (OR: 0.93, 0.88-0.99 per BMI unit), high alcohol consumption (OR: 0.5, 0.3-0.97 compared to moderate consumption), and parental diabetes (OR: 0.5, 0.3-0.9) significantly decreased the likelihood of NGT persistence. For BMI change, a borderline significance was found (OR, 95%CI: 1.9, 0.99-3.8 for BMI change <= -1kg/m^2 compared to BMI change > 1kg/m^2).
Conclusion: Reversion to NGT without specific interventions is not a rare event in older prediabetic subjects. Several factors modifiable by lifestyle (in particular weight change) have an influence on normalization of prediabetes as well as on persistence of NGT.

PS 14 HbA_{1c} as a diagnostic test

373

Assessment of glycated haemoglobin A_{1c} as a potential diagnostic tool in prediabetes and diabetes

T. Tankova, N. Chakarova, L. Dakovska, I. Atanassova;
Department of Diabetology, Clinical Center of Endocrinology, Sofia, Bulgaria.

Background and aims: During recent years there is an increasingly recognized need to develop strategies and criteria for diabetes screening and diagnosis that will allow effective early disease detection and will find out the possible utility of glycated hemoglobin A_{1c} (HbA_{1c}). The aim of the present study is to measure the level of HbA_{1c} in subjects with different glucose tolerance - normal glucose tolerance (NGT), impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and newly-diagnosed diabetes (NDD) and to evaluate the potential role of HbA_{1c} as a diagnostic tool for undetected diabetes and prediabetes (IFG and IGT).
Materials and methods: A total of 2134 subjects (899 males and 1235 females), of mean age 50.3±13.9 years and mean BMI 29.5±6.2 kg/m^2 were included in the study. According to their glucose tolerance they were divided into 4 groups - 1198 with NGT, 313 with IFG, 241 with IGT and 382 with newly-diagnosed screening-detected type 2 diabetes. All participants underwent a standard oral glucose tolerance test (OGTT) with 75g glucose and the categories of glucose tolerance were defined according to 2006 WHO criteria. Plasma glucose during OGTT - fasting and 2-hour level, was measured by a hexokinase enzyme method. HbA_{1c} was measured by an immunoturbidimetric method (COBAS INTEGRA 400, Roche Diagnostics GmbH, Mannheim, Germany). Statistical analysis of the data was performed by SPSS 16.0 for Windows (SPSS, Chicago, USA). Receiver operating characteristic (ROC) curve analysis was used to examine the sensitivity and specificity of HbA_{1c} for detecting diabetes and prediabetes.
Results: HbA_{1c} levels were significantly higher in all groups with altered glucose tolerance - 5.72±0.61% in IFG, 5.84±0.63% in IGT and 7.5±1.69% in NDD as compared to the group with NGT - 5.23±0.65% ($p<0.0001$ for all groups). There was significant difference in HbA_{1c} between the two prediabetic states ($p=0.02$), the level of HbA_{1c} of both groups being significantly lower as compared to NDD ($p<0.0001$). Significant positive correlation was established between the level of HbA1c and both fasting plasma glucose ($r=0.78$, $p<0.001$) and 2-hour plasma glucose ($r=0.76$, $p<0.001$). The ROC analysis demonstrated that HbA_{1c} had strong correlation with undiagnosed diabetes, with an area under the receiver operating characteristic curve (AUC-ROC) of 0.958 (95% CI: 0.946-0.970), as well as with undiagnosed prediabetes - AUC-ROC of 0.729 (95% CI: 0.702-0.755). The AUC-ROC for undiagnosed DM was similar between HbA_{1c} and fasting plasma glucose - 0.99 (95% CI: 0.983-0.997) and 2-hour plasma glucose - 0.982 (95% CI: 0.973-0.992). Analysis with ROC curves showed that the optimal cut-off level of HbA_{1c} for diagnosis of diabetes was 6.1% with a sensitivity of 86% and specificity of 92%. The optimal cut-off level of HbA_{1c} for undiagnosed prediabetes (IFG and IGT) appeared to be 5.5% with a sensitivity of 71% and specificity of 64%.
Conclusion: HbA_{1c} appears to be a sensitive and useful tool for identifying subjects with impairment in glucose tolerance (prediabetes and diabetes) and it should be considered in the development of diagnostic strategies.

The role of haemoglobin A_{1c} testing in diagnosing diabetes in Korean adults

H.-J. Lee[1], J.-Y. Oh[1], Y.-A. Sung[1], D.-J. Kim[2], S.-H. Kim[3], S.G. Kim[4], S. Moon[5], I. Park[6], E.-J. Rhee[7], C. Chung[8];
[1]Internal Medicine, Ewha Womans University, Seoul, [2]Internal Medicine, Inje University, Seoul, [3]Internal Medicine, Kwandong University, Seoul, [4]Internal Medicine, Korea University, Seoul, [5]Internal Medicine, Catholic University, Incheon, [6]Internal Medicine, Gachon University, Incheon, [7]Internal Medicine, Sungkyunkwan University, Seoul, [8]Internal Medicine, Yonsei University, Gangwon, Republic of Korea.

Background and aims: The international expert committee has recently recommended the use of HbA1C assay to diagnose diabetes, with a threshold of ≥ 6.5%. We aimed to characterize the cut off value of HbA1C in diagnosing diabetes based on 75-g oral glucose tolerance test (OGTT) in Korean adults.
Materials and methods: We recruited 902 adults (mean age 40±13(21~80) yrs, mean BMI 22.9±3.5 kg/m^2) without a self-reported history of diabetes from 8 university hospitals in 2009. A 75-g OGTT and HbA1C sampling were performed in all examinees. Glucose concentrations were measured by colorimetry method (ADVIA2400 autoanalyzer, Siemens, USA), and HbA1C was measured by immunoturbidimetric method (Cobas integra800, Roche, Switzerland) at the central laboratory. Receiver operating characteristic curve analysis was used to examine the sensitivity and specificity of HbA1C for diagnosing diabetes.
Results: The HbA1C threshold of 6.0% proved to be the optimal limit for diagnosing diabetes, with a 88.2% sensitivity and a 79.9% specificity. The cut off values increased with age (6.0% at ages 21~40, 6.2% at 41~60, and 6.4% at > 61 years) and were similar in both men and women (6.2 vs. 6.1%). HbA1C of ≥6.5% had a 53.8% sensitivity and a 98.3% specificity in detecting diabetes. This relatively low sensitivity may limit its use as a screening method for diabetes. Using the HbA1C ≥ 6.5% criteria, the positive predictive value (PPV) of OGTT based diabetes was 74.6%, with a negative predictive value (NPV) of 95.2%. And using the HbA1C ≥ 6.0% criteria, the PPV of OGTT based diabetes was 74.6%, with a NPV of 95.2%.
Conclusion: From our study, the cut-off value of HbA1C for diagnosing diabetes based on 75-g OGTT was 6.0%, and adjustment of this value by age would be needed. Further studies will be carried out to determine whether age-specific diagnostic criteria should be needed.

375

Screening for diabetes; inappropriate classification of "low risk"?

A.J. Dawson[1], J.M. Ng[1], K.A. Smith[2], D.D. Mellor[1], M.M. Aye[1], S.L. Atkin[1], E.S. Kilpatrick[2];
[1]Department of Diabetes and Endocrinology, University of Hull, [2]Department of Clinical Biochemistry, Hull and East Yorkshire NHS Trust, Hull, United Kingdom.

Background and aims: Recently there has been debate regarding screening strategies for type 2 diabetes (T2DM). Latest guidelines from the American Diabetes Association (ADA) and from the UK Department of Health in the United Kingdom (DoH) recommend the use of glycolysated haemoglobin (HbA1c) as a method of diagnosing T2DM in patients and also identifying patients at risk of developing the condition in the future. The threshold of 6.5% has been agreed upon by both parties as the diagnostic threshold for the diagnosis of T2DM. In the identification of patients at high risk of T2DM, the ADA has proposed an HbA1c of equal to or more than 5.7% as compared to DoH of 6.0%. Patients considered at high risk of developing DM should be offered diet/lifestyle interventions and recommended for regular screening in the future. This study sought to study the patients who had an HbA1c and a concurrent glucose tolerance test (OGTT) and to study the relationship between the two results with regard to these new proposed thresholds.
Materials and methods: During the period Jan 2007 to Nov 2009 inclusive, all patients who had an OGTT and HbA1c performed concurrently within our primary care trust were included in the analysis. Data was obtained from the laboratories services serving the area. All HbA1c results were calibrated through harmonisation to the DCCT (NGSP) assay. All patients tested for gestational diabetes or were pregnant were excluded from the analysis. The results were then stratified into groups with HbA1c of less than 5.7%, between 5.7 and 5.9% and more than 6.0% and OGTT result of either a fasting glucose of ≥7 mmol/L or a 2 hour reading of ≥ 11.1 mmol/L.
Results: There were a total of 835 patients who fit the criterion for analysis. (444M, 391F, median age 64 years (interquartile range 56-73). Using the ADA cut off of an HbA1c of less than 5.7%, 4.0% of all patients screened had an OGTT consistent with diabetes. Increasing the cut off to less than 6.0% (DoH guidelines) results in a further 58 patients (6.9% of all patients screened), i.e. in total 91 patients (10.9% of all screened) who would have been stratified as low risk despite their abnormal OGTT.
Discussion: In summary using a current ADA cut off of HbA1c 5.7% in the identification of patients at risk of developing DM fails to identify approximately 1 in 25 patients who may have overt diabetes mellitus. The DoH cut off of 6.0% results in a further 1 in 15 of patients who were classified as low risk. This results highlight a clinical concern as these patients may not receive another screening appointment for a prolonged period despite results which previously would have resulted them receiving appropriate intervention.

Table 1

	HbA1c < 5.7%	HbA1c 5.7-5.9%	HbA1c ≥ 6.0%
Normal OGTT	88 (10.5%)	98 (11.7%)	119 (14.3%)
Abnormal OGTT	33 (4.0%)	58 (6.9%)	439 (52.5%)
Total	121	156	558

376

Screening diabetes with HbA_{1c} and fasting plasma glucose

T. Yang, D. Yu, H. Zhou, G. Zhu;
Dept. Endocrinology, First Affiliated Hospital of Nanjing Medical University, China.

Background and aims: To examine the validity of glycated Haemoglobin Alc and fasting plasma glucose (FPG) as a screening test for type 2 diabetes.
Materials and methods: A total of 1330 Chinese subjects (433 male and 897 female) at an average age of 58.23±12.75 were enrolled. All subjects underwent a 75g oral glucose tolerance test (OGTT) and AlC measurement. Receiver operating characteristic curve (ROC curve) analysis was used to examine the sensitivity and specificity of FPG and Alc for detecting diabetes.
Results: Based on 1999 WHO criteria,944 had normal glucose tolerance(NGT),22 had impaired fasting glucose(IFG),236 had impaired glucose tolerance(IGT),37 had both of IGT and IFG,91 had diabetes. The prevalence of newly diagnosed diabetes was 6.84%. Based on the ROC curve, the optimal cut-point of FPG related to diabetes diagnosed by OGTT was 5.77 mmol/L which was associated with a sensitivity and specificity of 85.7% and 91.2% respectively. The area under the curve (AUC) is 0.923 (95%CI 0.881~0.964). The positive likelihood ratio is 9.74 while the negative likelihood ratio is 0.16. The optimal cut-point of Alc related to diabetes diagnosed by OGTT was 6.1%,which was associated with a sensitivity and specificity of 83.5% and 88.88% respectively. The area under the curve (AUC) is 0.905 (95% CI0.861~0.950). The positive likelihood ratio is 7.46 while the negative likelihood ratio is 0.19. The optimal cut-point of FPG related to IGT was 4.98mmol/L which was associated with a sensitivity and specificity of 65.2% and 65.2% respectively. The area under the curve (AUC) is 0.718(95%CI 0.684~0.752). The positive likelihood ratio is 1.87 while the negative likelihood ratio is 0.53. The optimal cut-point of HbAlc related to IGT was 5.7% which was associated with a sensitivity and specificity of 65.6% and 63.1% respectively. The area under the curve (AUC) is 0.680(95%CI 0.643~0.717). The positive likelihood ratio is 1.77 while the negative likelihood ratio is 0.55.
Conclusion: Compared with A1c, FPG has a greater value in diabetes screening, they have relativity in sensitivity, specificity, positive likelihood ratio and negative likelihood ratio. The subjects with HbA1c ≥ 6.1% or FPG ≥ 5.77mmol/L should be tested by OGTT to identify if they have diabetes or not.

Comparisons of the sensitivity and specificity with different diagnosis values for diabetes

Standard	Sensitivity (%)	Specificity (%)	Positive likelihood ratio	Negative likelihood ratio
FPG≥5.60mmol/L	85.7	88.5	7.45	0.16
FPG≥7.00mmol/L	62.6	100	∞	0.37
FPG≥5.77mmol/L	85.7	91.2	9.74	0.16
bA1c≥6.1%	83.5	88.8	7.46	0.19
FPG≥5.77mmol/L and HbA1c≥6.1%	78.0	95.2	16.25	0.23
FPG≥5.77mmol/L or HbA1c≥6.1%	93.4	78.6	4.36	0.08

Limitations of HbA_{1c} as a diagnostic test

A. Peter, E. Schleicher, H.-U. Häring, A. Fritsche;
Universität Tübingen, Germany.

Background and aims: Recent ADA recommendations have included glycated hemoglobin as a new diagnostic criteria for diabetes mellitus. However, glycation of hemoglobin is a complex process influenced by hereditary, racial and environmental factors as well as the hemoglobin turnover. Together, only about 50% of the variation in glycated hemoglobin levels is expected to be explained by blood glucose profiles. In this study, we have therefore compared the diagnostic value for diabetes of glycated hemoglobin and fasting and stimulated blood glucose concentrations after an oral glucose tolerance test according to the new ADA recommendations in a risk cohort.
Materials and methods: 2036 previously non-diabetic Caucasians at risk to develop type 2 diabetes consecutively underwent a 75g oral glucose tolerance test. Glycated hemoglobin was determined with the HPLC method (Tosoh A1c 2.2), external and internal quality controls were well within the allowed ranges.
Results: The oral glucose tolerance test classified 1523 individuals as *normal* glucose tolerant (NGT), 387 as impaired glucose tolerant (IGT) or impaired fasting glycemia (IFG) and 126 as diabetic. Using the newly recommended glycated hemoglobin cut-off for diabetes of 6.5%, 53 % of the diabetic individuals were not detected. In our cohort, 2-h plasma glucose but not fasting glucose identifies 65% of all diabetic patients with glycated hemoglobin <6.5%. 39% of the diabetic patients' glycated hemoglobin was in the intermediate range of 5.7-6.5% . To diagnose these patients, one third of the total cohort with a glycated hemoglobin in the intermediate range would need to undergo a re-screening by an OGTT. Still, one in seven diabetic subjects had a glycated hemoglobin below 5.7% and would remain undiagnosed.
Conclusion: Aiming to prevent glucotoxic beta-cell destruction at an early stage of the disease, increased postprandial blood glucose values need to be diagnosed and treated. Therefore, despite the intriguing simplicity, glycated hemoglobin has obvious limitations to diagnose diabetes and prevent its complications.

378

The HbA_{1c} cut points for detecting type 2 diabetes and prediabetes in a risk population - is this the right way?

C. Koehler, E. Henkel, F. Schaper, M. Hanefeld;
Center for Clinical Studies, GWT-TUD GmbH, Dresden, Germany.

Background and aims: The study's aim was to evaluate the adequacy of a HbA1C cut point as screening tool to detect type 2 diabetes (T2DM) and prediabetic stages in a risk population for diabetes.
Materials and methods: A total of 1,028 middle aged (40-70 years) German participants of the Risk factors in IGT for Atherosclerosis and Diabetes study (RIAD) without known diabetes were included. A standardized 75g OGTT was performed after an overnight fasting period. As the basis for the classification of diabetes and its prediabetes stages it was applied the definition by WHO. Plasma glucose was measured by hexokinase method and HbA1C by HPLC. Based on the method of the receiver operating characteristic curve (ROC) the optimal cut point for T2DM, impaired glucose tolerance (IGT) and impaired fasting glucose (IFG) with sensitivity and specificity was calculated.
Results: The prevalence of newly detected T2DM was 13.8%, of IGT 25.7% and IFG 10.6%. The cut points with the corresponding values for sensitivity and 1-specificity were prepared in the table.
Conclusion: The results of the HbA1C measurement (as screening tool for newly diagnosed T2DM and the prediabetic stages) suggest in this risk population a sensitivity of approx. 65% but a high rate of false positive tests between 21 and 48%. This indicates that HbA1C could not appropriate to detect T2DM and prediabetes in a risk population. The physicians should assess the individual risk of the patient and in case of high risk should perform an OGTT to evaluate the glycemic state.

HbA1C cut points for the hyperglycemic stages

	HbA1C cut point value (%)	AUC	Sensitivity	1-specificity
T2DM	6.0	0.80	0.66	0.21
IGT	5.6	0.62	0.67	0.48
IFG	5.6	0.65	0.63	0.44

379

The HbA_{1c} assays in population diabetes screening in Eastern Poland

G. Mardarowicz, T.A. Nicer;
Family Medicine Department, Lublin, Poland.

Background and aims: The glycosylated haemoglobin (HbA1c) assay is the test of choice for the metabolic control of diabetes (DM). In recent time it is recommended also for its diagnosis. The aim of the study was to evaluate the diagnostic utility and limitations of HbA1c in screening for DM in adult population of Eastern Poland.
Materials and methods: In the representative sample of adult population of the Lublin region chosen from the general population by two layer drowning, the oral glucose tolerance test (OGTT) , estimation of blood lipids , evaluation of blood pressure , body mass index (BMI) at baseline (1999-2001), and at 5th yr follow-up (2004-2005) were performed. DM was diagnosed according to WHO criteria. HbA1c was determined in 2170 of 3781 survey par-

ticipants (mean age 55,9±12,3) at baseline screen and it was repeated in 386 subjects in follow-up. HbA1c assay was performed by LPLC chromatography standardized by NGSP. The diagnostic usefulness of HbA1c was evaluated using ROC (Receiver or operating characteristic) curve analysis.
Results: The mean value of HbA1c in 1294 subjects with normal OGTT was 5,4± 0.54% ,in 617 subjects with impaired glucose tolerance- 5,55 ±0.6%, in 214 subjects with newly detected DM - 5,96 ±1.13%, and in 40 - with known DM- 7,1 ±1.64% .The HbA1c didn't change significantly in a group of 253 subjects during 5 year long prospective observation (5,51±0,48 vs 5,49±0,51%). In follow-up study 240 newly detected diabetics were recognised. The baseline cut- off point of HbA1c in ROC curve for future diabetes was estimated at 5,3% (75,2% sensitivity, 50,1% specificity). The HbA1c value ≥6.5% was found in 154 subjects (14,1% of studied cases). Among them 65 subjects were diagnosed by WHO criteria as diabetic and 52 subjects had DM diagnosis by ADA criteria. As the cut-off point of 6.5% is related more to the risk of diabetic complications than single measures of glucose concentrations, the ADA criteria didn't captured 66%, and WHO criteria -58% of high risk individuals. The sensitivity/specificity of A1c cut-off point of 6,5% was in our population 16/97%.
Conclusion: Our results are consistent with data from US population study with comparable sample size and similar age. The diagnostic utility of HbA1c with recommended cut-off point of 6,5% is limited by low sensitivity of test assessed in polish population on 16%.

Detection of diabetes in coronary artery disease: oral glucose tolerance test or glycated haemoglobin and fasting plasma glucose?
E. Delgado[1], J.M. De la Hera[2], I. Lozano[2], E. Hernandez[2], J.M. Vegas[3], C. Fernandez-Cimadevilla[2], F. Torres[2], A. Carro[2], J. Bayon[2], J.M. Garcia-Ruiz[2], P. Avanzas[2];
[1]Endocrinology, Hospital Universitario Central de Asturias, Oviedo, [2]Cardiology, Hospital Universitario Central de Asturias, Oviedo, [3]Cardiology, Hospital Clínico Universitario, Valladolid, Spain.

Background and aims: The proposal of the ADA of incorporating the glycated hemoglobin (A1C) in the diagnosis of the newly detected diabetes (NDD) may interfere with the recommendation of the EASD about performing the oral glucose tolerance test (OGTT) in patients with coronary artery disease without known diabetes. We sought to determine the impact of both test, A1C and OGTT, in the diagnosis of diabetes in our series.
Methods: We analysed 338 patients with coronary artery disease without known diabetes treated with percutaneous intervention. Two weeks after discharge an analysis including fasting plasma glucose (FPG), OGTT and A1C was performed. Newly detected diabetes was diagnosed by FPG if glucose ≥126 mg/dl; by A1C if FPG< 126 mg/dl and A1C≥6.5% and by OGTT if FPG< 126 mg/dl and A1C< 6.5% and glucose post-challenge ≥200 mg/dl.
Results: Age 66.5 (56-74), males 80.1%, hypertension 49.7%, obesity 35.5%, previous myocardial infarction 37.3%. After the analysis the metabolic profile of the series was: NDD 77 patients (22.8%), prediabetes 146 (43.2%) and normoglycemic 115 (34%). Of the totality of patients diagnosed of NDD, in 19 (24.6%) the diagnosis was by FPG, 5 (6.4%) with the A1C and 53 (69%) by OGTT.
Conclusion: In our series a screening of diabetes in patients with coronary artery disease based in the FPG and A1C only diagnoses 31% of the real NDD. The OGTT is still absolutely necessary to rule out the NDD in this population.

Proposal to rule out the unknown diabetes in patients with coronary disease
J.M. De la Hera[1], J.M. Vegas[2], I. Lozano[1], E. Hernandez[1], J.M. Garcia-Ruiz[1], J. Bayon[1], C. Fernandez-Cimadevilla[1], F. Torres[1], S. Secades[1], T. Menendez[3], P. Avanzas[1], E. Delgado[3];
[1]Cardiology, Hospital Universitario Central de Asturias, Oviedo, [2]Cardiology, Hospital Clinico Universitario, Valladolid, [3]Endocrinology, Hospital Universitario Central de Asturias, Oviedo, Spain.

Background and aims: The EASD recommends to perform an oral glucose tolerance test (OGTT) to all the patients with coronary disease without known diabetes. This proposal needs to be balanced with three facts: the OGTT is not usually performed in daily practice, the key in this population is the diagnosis of unknown diabetes (UDM) because the presence of prediabetes would not substantially modify its secondary prevention and lastly the inclusion of the glycated hemoglobin (A1C) in the diagnosis of diabetes. We sought to validate a new score to rule out the presence of UDM in patients with coronary disease, selecting the indication of the OGTT.
Materials and methods: In a cohort of 338 patients without known DM, we perfectly characterized the glycometabolic profile with fasting plasma glucose (FPG), OGTT, A1C and insulinemia, the coronary risk factors and the extension of the coronary disease. With a logistic regression analysis the predictors of UDM by the OGTT (defined as glucose postchallenge>200 mg/dl) were determined and a score was assigned to each patient.
Results: Seventy-seven of the 338 patients presented UDM, 146 prediabetes and 115 were normoglycemics. Thirty-one percent of the UDM could be diagnosed only with the FPG and A1C. The predictors of UDM in OGTT were: Age> 65 years (OR 2.8 (1.2-5.2), p=0.015, 3 points), non-coronary vascular disease (OR 2.6 (1.2-5.9) p=0.018, 3 points), ejection fraction<45% (OR 2.7 (1.03-7) p=0.044, 3 points), FPG> 100 mg/dl (OR 4.74 (2.4-9.5) p<0.001, 5 points) and A1C>6.1% (OR 5.8 (1.5-21.7) p=0.009, 6 points). The best cut-off point was established in >6 points (AUC 0.80, CI 95% (0.74-0.87) p<0.001). Thus, performing the OGTT to 31% of the population and together with the diagnosis by FPG and A1C it is possible to localize 83% of the real cases of UDM.The score was validated in another series of 115 patients with very close reproductability (AUC 0.84, CI 95% (0.74-0.95) p<0.001).
Conclusions: A systematic screening with FPG and A1C and performing the OGTT only depending on the risk assessed by our score (31% of the population) allows the diagnosis of 83% of the UDM.

Differences in cardiovascular risk profile of diabetic subjects discordantly classified by diagnostic criteria based on glycated haemoglobin and the oral glucose tolerance test
L. Lopez Rios[1], M. Boronat Cortés[2,1], P. Saavedra[3], M. Riaño[4], A.M. Wägner[2,1], F.J. Nóvoa[2,1];
[1]Dtpo. Ciencias Médicas y Quirúrgicas, Universidad de Las Palmas de GC, [2]Sección de Endocrinología, Complejo Hospitalario Universitario Insular Materno Infantil de Gran Canarias, [3]Dtpo. Matemáticas, Universidad de Las Palmas de GC, [4]Servicio de Bioquímica, Complejo Hospitalario Universitario Insular Materno-Infantil, Las Palmas de GC, Spain.

Background and aims: Last year, an International Expert Committee advocated the use of glycated haemoglobin A1C testing for diagnosis of diabetes. Based on the correlation between A1C levels and risk of retinopathy in several epidemiological studies, the committee determined that an A1C value of 6.5% or greater should be used as the diagnostic threshold. Guided by this report, several leading organizations, including the American Diabetes Association (ADA), have approved the use of A1C as an additional criterion for diagnosing type 2 diabetes. The present study assesses the differences in the cardiovascular risk profiles of subjects differently categorized as having or not having diabetes with diagnostic criteria based on plasma glucose and A1C proposed by the 2010 American Diabetes Association clinical practice recommendations.
Materials and methods: A standard oral glucose tolerance test (OGTT), A1C, and a set of cardiovascular risk factors and indirect measures of insulin resistance and insulin secretion were assessed in 964 individuals without previously known diabetes participating in the Telde Study, a cross-sectional epidemiological survey in Gran Canaria, Canary Islands, Spain.
Results: Taking the OGTT as the golden standard, the sensitivity and specificity of an A1C value ≥ 6.5% were 38.7% and 99.6%, respectively. Only four subjects diagnosed with diabetes by A1C did not also fulfil OGTT-based diagnosis. Those who met both diagnostic criteria presented greater measures of BMI and waist circumference, and higher values for fasting and 2-h plasma glucose, HOMA-IR, plasminogen activator inhibitor-1 and fibrinogen than subjects with diabetic OGTT but A1C < 6.5%. Abdominal obesity and 2 hours plasma glucose were the only variables independently associated with an A1C value ≥ 6.5% in a multivariate regression analysis.
Conclusion: Newly diagnosed diabetic individuals who fulfill both glucose and A1C-based diagnostic criteria for the disease seem to display a more unfavorable cardiovascular risk profile than individuals who meet the glucose-based but not A1C-based criteria.

PS 15 Anthropometric and clinical predictors of type 2 diabetes mellitus

383

Prediction of incident type 2 diabetes in Norwegians using simple anthropometric measures - the HUNT study

C.M.Y. Lee[1], S. Colagiuri[1], M. Woodward[2], K. Midthjell[3];
[1]Boden Institute of Obesity, Nutrition and Exercise, The University of Sydney, [2]The George Institute for International Health, Sydney, Australia, [3]HUNT Research Centre, Norwegian University of Science and Technology, Levanger, Norway.

Background and aims: Waist circumference cut-points have been used to indicate increased risk of diabetes and cardiovascular disease. The cut-points for Caucasians have been recommended, however, based on limited data. Moreover, it is still uncertain if measures of abdominal obesity such as waist circumference and waist-to-hip ratio are superior at predicting diabetes risk over body mass index. The aims were, therefore, to establish which simple anthropometric measure best predicts incident type 2 diabetes, and to determine the optimal cut-points of each anthropometric measure for the prediction of incident type 2 diabetes in Caucasians.
Materials and methods: Participants without known diabetes at the Norwegian HUNT second survey (HUNT 2) who also participated in the third survey (HUNT 3), with height, weight, waist and hip circumferences measured at HUNT 2, and diabetes outcome at HUNT 3 were included. Receiver operating characteristic curves were used to assess discrimination of type 2 diabetes, separately, for men and women.
Results: A total of 34293 participants (55% female) with 1176 new cases of type 2 diabetes were included in the analyses. The area under the curves for waist-to-height ratio (0.783 for men; 0.821 for women) and waist circumference (0.768 for men; 0.810 for women) were larger than for body mass index (0.760 for men; 0.797 for women). The optimal cut-points for men were 27.8 kg/m^2 for body mass index (sensitivity 67%; specificity 71%), 95 cm for waist circumference (sensitivity 70%; specificity 70%), 0.90 for waist-to-hip ratio (sensitivity 76%; specificity 62%), and 0.53 for waist-to-height ratio (sensitivity 71%; specificity 71%). For women, the respective cut-points were 26.8 kg/m^2 (sensitivity 81%; specificity 66%), 85 cm (sensitivity 76%; specificity 71%), 0.81 (sensitivity 76%; specificity 66%), and 0.51 (sensitivity 81%; specificity 68%).
Conclusion: Measures of abdominal obesity were superior to body mass index in the prediction of type 2 diabetes. There was, however, no statistical difference to suggest clinical advantage of one measure over another. The optimal cut-points for body mass index in both sexes and for waist circumference in women were higher than those currently applied to Caucasians. Hence, the current anthropometric cut-points for Caucasians, or at least for Norwegians, may be inappropriate. These results should inform risk prediction algorithm in Caucasians.

384

Waist circumference and body mass index as predictors of prediabetes and type 2 diabetes in middle-aged Swedish women and men

A. Hilding, C.-G. Östenson;
Dept. of Molecular Medicine and Surgery, The Endocrine and Diabetes Unit, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Obesity is an important risk factor for type 2 diabetes (T2D). Waist circumference (WC) and body mass index (BMI), measurements of central fat distribution and general obesity, respectively, are used to predict T2D. Recently, in a 7-yrs follow-up study of older subjects (mean age 69 yrs at baseline) it was shown that WC and BMI yielded similar prediction in men, whereas WC was a superior predictor of T2D in women. The aim of the present population-based study was to evaluate WC and BMI as predictors of T2D, as well as of prediabetes (IFG, IGT), in a cohort of younger Caucasian subjects and in separate analysis for men and women.
Materials and methods: Subjects having normal glucose tolerance (NGT) at baseline, 3190 women (48±5 yrs, mean±SD) and 2215 men (47±5 yrs), participants of Stockholm Diabetes Prevention Program, were again at follow-up, 8-10 years later, investigated with an oral glucose tolerance test (OGTT). T2D, including also those who were diagnosed with T2D during the time period between baseline and follow-up, IFG and IGT was detected in 59 (1.8%), 41 (1.3%) and 120 (3.8%) women and in 107 (5.0%), 81 (3.7%) and 126 (5.7%) men, respectively. Logistic regression analysis was performed and receiver operating characteristic (ROC) curves, with corresponding area under curve (AUC), evaluated the predictive power of WC and BMI, measured at baseline.
Results: In univariate analysis, both WC and BMI were strongly associated with the development of IFG, IGT and T2D in women and men, p<0.001. In women, WC and BMI predicted IFG similarly, ROC-AUC was 0.73 (0.67-0.81, 95% CI) for WC and 0.75 (0.69-0.81) for BMI. However, for IGT and T2D WC was a stronger predictor in women; ROC-AUC was 0.70 (0.65-0.75) as compared to 0.67 (0.62-0.72), p=0.034, for IGT, and corresponding values for T2D were 0.80 (0.74-0.86) vs. 0.76 (0.69-0.83), p=0.010. In men, BMI was superior to WC in the prediction of IFG, ROC-AUC was 0.65 (0.59-0.70) vs. 0.59 (0.53-0.65), p=0.005, whereas the two measurements predicted similarly for IGT and T2D. The BMI ROC-AUCs were 0.67 (0.62-0.72) and 0.68 (0.63-0.73) and the WC ROC-AUCs were 0.65 (0.59-0.70) and 0.67 (0.61-0.72) for IGT and T2D, respectively. The optimal cut-off point for WC in the prediction of T2D, using optimal sensitivity and specificity, was 83 cm in women and 96 cm in men.
Conclusion: In middle-aged men BMI is equal or better than WC in the prediction of prediabetes and T2D. In contrast, in women WC is the equal or stronger predictor. The cut-off points for WC in the prediction of T2D are close to the values of the metabolic syndrome definition according to the International Diabetes Federation.

385

Optimal waist circumference cutoff value predicting the incident type 2 diabetes as a diagnostic criterion of metabolic syndrome in Korean population aged 40 years and over: the Chungju Metabolic Disease Cohort study (CMC study)

Y.-M. Park[1], H.-S. Kwon[2], H.-S. Ha[1], S.-H. Lee[2], J.-H. Lee[3], H.-W. Yim[1], K.-H. Yoon[2], M.-I. Kang[2], H.-Y. Son[2], W.-C. Lee[1];
[1]Department of Preventive Medicine, [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, [3]The Catholic Institute of Ubiquitous Healthcare, The Catholic University of Korea, Seoul, Republic of Korea.

Background and aims: In 2009, a joint statement of the International Diabetes Federation (IDF); the National Heart, Lung, and Blood Institute (NHLBI); the American Heart Association (AHA); the World Heart Federation; the International Atherosclerosis Society; and the International Association for the Study of Obesity proposed a harmonized definition of metabolic syndrome (MetS) in which the presence of any three of five risk factors comprises a diagnosis of MetS. This new definition of MetS recommends that the IDF cutoff points of waist circumference (WC) be used for non-Europeans until more data are available. Several WC cutoffs for Korean population have been proposed, however, their results have limitation of cross-sectional studies. We aimed at determining the cutoff value of waist circumference as a diagnostic criterion of metabolic syndrome with respect to its ability to predict the incident type 2 diabetes in a Korean population.
Materials and methods: The Chungju Metabolic Disease Cohort (CMC) study that began in 2003 is an ongoing community-based cohort study of metabolic disease including type 2 diabetes and metabolic syndrome in a population aged 40 years and over. We conducted a baseline study using stratified random cluster sampling between 2003 and 2006. A total of 3,815 non-diabetic subjects (1,474 men and 2,341women) without a history of ischemic heart disease and cerebrovascular disease were followed up for an average of 4.5 years. Receiver operating characteristic (ROC) curve analysis using Youden index and the area under curve (AUC) was applied. In addition, we performed a multivariate Cox proportional hazard model adjusting age, BMI, smoking, and smoking, drinking alcohol, exercise, and dietary habits to evaluate the relative risk of development of type 2 diabetes according to the WC category for men and women.
Results: In the ROC curve analysis for the different WC cutoffs including 80 cm, 85 cm, and 90 cm, the highest value of Youden index was obtained at a WC cutoff point of 85 cm for both sexes. Sensitivity and specificity were 55.7% and 66.4% in men and 60.0% and 54.7% in women, respectively. After being controlled for other covariates, the relative risks for the development of type 2 diabetes tended to increase significantly, especially in women, as WC incremented. In addition, the relative risk for the development of type 2 diabetes using <75 cm of waist circumference as a reference increased sig-

nificantly in the category of 85-89.9 cm for women. Statistically significant associations also were consistently observed over the category of 85-89.9 cm for women.
Conclusion: The optimal cutoff value for waist circumference predicting the incident type 2 diabetes is considered to be 85 cm, especially in women, suggesting that the Asian criterion of abdominal obesity (90 cm for men and 80 cm for women) as a component of metabolic syndrome might not be applicable for middle-aged to older population in Korea.

Association of body height with diabetes, blood pressure and metabolic syndrome among Sri Lankan adults
P. Ranasinghe[1], M.A.R. Jayawaradena[1], G.R. Constantine[1], R. Sheriff[1], D.R. Matthews[2], P. Katulanda[1];
[1]Department of Clinical Medicine, Diabetes Research Unit, Colombo, Sri Lanka, [2]Oxford Center for Diabetes Endocrinology and Metabolism, United Kingdom.

Background and aims: Being tall has been suggested to be associated with better cardio-vascular health and longevity. Height, a marker of childhood growth, is associated with lower mortality and morbidity from diabetes mellitus and from associated risk factors. It is thought that better childhood conditions, such as improved nutrition and fewer respiratory infections, result in both greater adult height and lower rates of chronic non-communicable diseases. We aimed to report the relationship of height with diabetes mellitus, blood pressure (BP) and metabolic syndrome (MS) among Sri Lankan adults
Materials and methods: Data were available for height and socio-demographic factors from a nationally representative cross-sectional sample of 4477 subjects above 18 years. Recruitment was preformed between 2005-2006. Height was measured using Harpenden pocket stadiometers to the nearest 0.1 cm according to the standard methods. Subjects were considered to have 'diagnosed diabetes' if they had been previously diagnosed at a government hospital or by a registered medical practitioner. New cases ('undiagnosed diabetes') and metabolic syndrome were diagnosed according to World Health Organization criteria Seated blood pressure was recorded on two occasions after at least a 10-min rest using an Omron IA2 digital blood pressure monitor. Data were analysed using SPSS.
Results: Males were 39.5% and mean age of all subjects was 46.1 (SD±15.1) years. The mean height of all adults, males and females were 156.2±8.9cm, 163.6±6.9cm and 151.4±6.4cm respectively (p<0.001, males vs. females). In all adults Height showed a significant negative correlation with fasting blood glucose (p<0.05, r= -0.052), 2-hour post-glucose blood glucose levels (p<0.001, r = - 0.089) and diabetes (p<0.001, r = -0.069). There was a significant negative correlation between mean systolic BP and height (p<0.05, *r* = -0.032), this was not observed for the mean diastolic BP. Height demonstrated significant correlations with total cholesterol (p<0.001, *r* = -0.106), HDL cholesterol (p<0.001, *r* = -0.142), LDL cholesterol (p<0.001, *r* = -0.104) and triglyceride (p<0.001, *r* =0.064) levels. Similar changes were observed in both genders (Table 1). The mean heights of patients with MS and without MS were 154.8 ± 8.8 cm and 156.6 ± 8.9 cm respectively (p<0.001).
Conclusion: Our data showed a negative correlation between height and blood glucose levels, serum cholesterol levels and mean systolic BP. Also patients with MS were significantly shorter than those without MS. These data suggest that being tall reduces diabetes and cardiovascular risks and the underlying mechanisms needs further study.

Table:1 Relationship between height and metabolic parameters (*p<0.05)

Metabolic parameter	Correlation coefficient (*r*)		
	All	Male	Female
Fasting blood sugar	-0.052*	-0.068*	-0.052*
2 hour post glucose blood sugar	-0.089*	-0.062*	-0.089*
Presence of diabetes	-0.069*	-0.105*	-0.069*
Mean systolic blood pressure	-0.032*	-0.097*	-0.123*
Mean diastolic blood pressure	-0.028	-0.010	-0.029
Total cholesterol	-0.106*	-0.117*	-0.103*
LDL cholesterol	-0.104*	-0.102*	-0.083*

Neck circumference positively related with central obesity, overweight and metabolic syndrome in Chinese people with type 2 diabetes
G. Yang, S. Yuan, H. Fu;
Endocrinology, Tongren Hospital, Beijing, China.

Background and aims: To investigate the association between neck circumference and central obesity, overweight as well as metabolic syndrome in Chinese individuals with type 2 diabetes.
Materials and methods: Subjects with type 2 diabetes (age 20-80 years) were recruited from 15 community health centers in Beijing using a multi-stage random sampling approach. Anthropometrics, including neck and waist circumference measurement was conducted. Metabolic syndrome was identified based on criteria of WHO. Central obesity was diagnosed according to criteria of IDF.
Results: 3182 diabetics (1294 men and 1888 women) without thyroid swelling, were enrolled with mean (±SD) age of 64.0±10.1 years. The diabetic duration was 9.37±6.56 years. The mean neck circumference was 36.6±3.7 cm, 38.4 ±3.6 cm for men, and 35.4±3.3 for women (p<0.001). Receiver operating characteristics (ROC) analysis showed that the area under the neck-circumference-and-central-obesity curve was 0.74 (95% C.I. (0.72, 0.77)) for men, and 0.75 (95% C.I. (0.72, 0.78)) for women (p<0.001). Furthermore, neck circumferences of ≥39 cm (with sensitivity of 56.3% and specificity of 79.2%) for men and ≥36cm (with sensitivity of 61.1% and specificity of 73.1%) for women were best cutoff levels for determining people with BMI ≥25.0 kg/m^2.Neck circumferences of ≥ 38 cm for men ,and ≥ 36 cm for women were best cutoff levels for determining people with metabolic syndrome. After adjusting with gender and age, neck circumference was associated significantly with metabolic syndrome (OR, 1.13 [95% C.I. (1.10-1.17)).
Conclusion: In the present study, neck circumference is positively related with body mass index, waist circumference and metabolic syndrome in Chinese people with type 2 diabetes. The neck circumference might be used in clinical convenient index as a predictor for central obesity and metabolic syndrome. Further studies are needed for closer identification of this association in general population.

Impaired insulin sensitivity and beta cell function predict the onset of diabetes in non-diabetic women with former gestational diabetes
A. Grassi[1,2], A. Tura[1], G. Pacini[1], A. Mari[1], Y. Winhofer[3], A. Kautzky-Willer[3];
[1]Metabolic Unit, ISIB-CNR, Padova, [2]Department of Information Engineering, University of Padova, Italy, [3]Department of Internal Medicine III, Medical University of Vienna, Austria.

Background and aims: Gestational diabetes mellitus (GDM) is the specific type of diabetes that may develop during pregnancy. After delivery, women with previous GDM (pGDM) often normalize their glucose levels, but they are at increased risk of developing type 2 diabetes, especially if they have other risk factors (i.e. obesity, hypertension, family history of type 2 diabetes). In this context, it is important to see whether there are indications in pGDM immediately after delivery about their possible development of overt diabetes. Aim of this study was the analysis of possible differences in insulin sensitivity and beta cell function between non-diabetic pGDM developing diabetes within 3-5 years from delivery and those who instead remained non-diabetic.
Materials and methods: A total of 77 pGDM were studied with a 75-g 3h oral glucose tolerance test (OGTT) at baseline (i.e., immediately after partum) and during the 5 year study period. Insulin sensitivity was evaluated with the oral glucose sensitivity index (OGIS), while beta cell function through mathematical modelling of C-peptide, that yields B-cell sensitivity to glucose stimulus (BGS) and early insulin response (rate sensitivity, BRS). After the baseline examination, at a following visit the OGTT of 17 women matched the ADA/WHO criteria for diabetes (progressors, PROG), while in the remaining 60 women no sign of diabetes was found (NON-PROG).
Results: In Table 1, subjects' characteristics and metabolic parameters at baseline are shown. PROG were slightly older and with higher BMI. Glucose, both fasting and during OGTT, was more elevated in PROG, while insulin was not significantly different, yielding lower insulin sensitivity (OGIS). Beta cell response was markedly impaired in PROG, especially the beta cell sensitivity to glucose (BGS) which was 40% lower.

Conclusion: Non-diabetic women with previous GDM developing diabetes within 3-5 years exhibit lower insulin sensitivity and B-cell function than pGDM who remain non-diabetic. The assessment of these metabolic parameters immediately after delivery could therefore be very useful to characterize the subjects at particularly high risk in order to start early prevention against the development of diabetes.

Table 1

	NON-PROG	PROG	p-value
Age (years)	33.4 ± 0.5	36.2 ± 1.2	0.0337
BMI (kg m^{-2})	25.6 ± 0.5	31.8 ± 1.7	<0.0001
Fasting plasma glucose (pmol l^{-1})	4.80 ± 0.06	5.45 ± 0.16	<0.0001

Contribution of different biomarkers to risk of type 2 diabetes

J. Montonen[1], D. Drogan[1], H.-G. Joost[1], H. Boeing[1], A. Fritsche[2], E. Schleicher[2], M.B. Schulze[3], T. Pischon[1];
[1]German Institute for Human Nutrition Potsdam-Rehbruecke, Nuthetal, [2]University of Tuebingen, [3]Technische Universität München, Freising, Germany.

Background and aims: Over the past years, a number of circulating blood biomarkers have been identified and proposed as predictors of type 2 diabetes. In the present study we quantified to what extent biomarkers of different metabolic pathways contribute to the risk of type 2 diabetes.
Materials and methods: The contribution of different biological pathways to the development of type 2 diabetes was estimated in a case-cohort design based on circulating blood biomarkers from participants aged 35 - 65 years in the EPIC-Potsdam Study. The analytic sample included 613 participants with incident diabetes and 1965 participants without diabetes. We constructed a biomarker score based on plasma values of glycated haemoglobin (HbA1c), gamma-glutamyltransferase (GGT), HDL-cholesterol, hs-CRP, and adiponectin. Cox proportional hazard regression was used to estimate relative risks adjusted for age, sex, body mass index, waist-circumference, education, sport activity, cycling, occupational activity, and smoking and alcohol intake. The proportion of the association between the score and diabetes risk explained by each biomarker was estimated using effect decomposition method by entering quintiles of glycated haemoglobin (HbA1c), gamma-glutamyltransferase (GGT), HDL-cholesterol, CRP, and adiponectin simultaneously in the model.
Results: The relative risk of type 2 diabetes between extreme quintiles of the overall biomarker index score was 14.6 (95% confidence interval (CI): 6.81, 31.2; P<0.001). A total of 27.7% (CI: 22.0, 34.1) of the risk was explained by HbA1c. For the other biomarkers the corresponding proportions were 11.5% (CI: 5.53, 17.7) by GGT, 14.4% (CI: 8.67, 20.3) by HDL-cholesterol, 6.45% (CI: -0.38, 13.4) by hs-CRP, and 13.5% (CI: 6.98, 20.3) by adiponectin.
Conclusion: The results support the hypothesis that different biological pathways reflected by markers such as HbA1c, GGT, HDL-cholesterol, and adiponectin play a role in the development of type 2 diabetes independently from each other.

Association between liver markers and insulin sensitivity, insulin secretion and endogenous glucose production in non-diabetic individuals

F. Bonnet[1], M. Laville[2], B.J. Balkau[3], on behalf of the RISC Study investigators; [1]Dept of Endocrinology-Diabetology, University hospital; Inserm U625, Rennes, [2]Inserm U870-Inra 1235, Centre de Recherche en Nutrition humaine Rhône-Alpes, Lyon, [3]INSERM CESP U1018, Villejuif, France.

Background and aims: An association between elevated concentrations of gammaglutamyl transferase (GGT) and alanine aminotransferase (ALT) with the risk of type 2 diabetes has been shown. However, the underlying pathophysiological mechanisms remain poorly determined. The aim of our study was therefore to explore whether a modest elevation of liver markers is associated with insulin resistance and/or altered insulin secretion.
Materials and methods: We studied 1310 healthy individuals from the RISC study (Relationship between Insulin Sensitivity and Cardiovascular disease). All participants had a euglycemic-hyperinsulinemic clamp and an OGTT with determination of indices of insulin secretion. A subgroup of 409 also had an assessment of endogenous glucose production (EGP) with a tracer.
Results: Both fasting and 2 h glycaemia progressively increased over GGT and ALT quartiles. Insulin sensitivity (as assessed by the M/I value) was inversely correlated to the plasma concentration of GGT or ALT (r=-0.30, p<0.0001 for each). Modest elevations in liver markers were significantly associated with an increase risk of insulin-resistance (defined as the M/I value in the first quartile) after adjustment for age, sex, physical activity and waist: GGT>20 UI/l, OR :1.80 (1.3-2.5), p=0.0007; ALT>20 UI/l, OR :1.59 (1.2-2.2), p=0.004. There was no association between aspartate aminotransferase levels and insulin sensitivity. The hepatic insulin resistance index (EGP x fasting insulinaemia) was more strongly correlated with GGT (r=0.29, p=0.0001) than with ALT levels (r=0.16, p=0.02). These significant associations persisted in multivariate models. GGT and ALT levels were positively correlated with fasting glucagon and inversely to adiponectin concentrations. Insulin secretion, as assessed by the disposition index, was not significantly associated with liver markers. In multivariate models, GGT and ALT were independent determinant of 2h glycaemia during the OGTT.
Conclusion: GGT and ALT, even at moderately elevated levels, are closely linked to both peripheral and hepatic insulin resistance but not with insulin secretion, in healthy non-diabetic individuals. This confirms the pertinence of these markers to identify insulin resistant individuals at high risk of type 2 diabetes.

Urinary myo-inositol is a useful and cost-effective marker to detect glucose intolerance: a community-based "Tottori-Kofu" study

H. Shiochi[1], H. Shimohiro[2], S.-I. Taniguchi[1], N. Yamamoto[1], Y. Fujioka[1], K. Sumi[1], K. Matsuzawa[1], S. Izawa[1], H. Kinoshita[1], T. Ohkura[1], H. Ohkura[1], K. Inoue[3], M. Takechi[4], C. Shigemasa[1];
[1]Division of Molecular Medicine and Therapeutics, Department of Mutidisciplinary Internal Medicine, Tottori University Faculty of Medicine, Yonago, [2]Department of Pathobiological Science and Technology, School of Health Science, Tottori University, Yonago, [3]Hino Hospital, [4]Ebi Clinic, Kofu, Japan.

Background and aims: Myo-inositol is one of 9 inositol stereoisomers with cyclic sugar alcohol and its composition is like D-glucose. Myo-inositol exists in human tissues. The urinary excretion of myo-inositol is augmented in diabetes patients, since the ascent of plasma glucose obstructs the re-absorption of myo-inositol in renal uriniferous tubule. Consequently, urinary myo-inositol excretion indirectly reflects plasma glucose level. Therefore, urinary myo-inositol could be a useful marker of glucose intolerance. We performed Tottori-Kofu study, which was designed to pick up patients with impaired glucose tolerance(IGT). We applied 75gOGTT as the most effective strategy to detect IGT. However, OGTT requires much time and cost. We presumed urinary myo-inositol could be a good candidate marker to detect IGT. In this study, we aimed to estimate urinary myo-inositol value in OGTT.
Materials and methods: We performed 75gOGTT in 110 people (male 35, female 75, average age 68.3 years old). In OGTT, we collected blood samples before, 30, 60 and 120 min. after glucose loading. Urine samples were also taken before and 120 min. after glucose loading. According to OGTT results, we segmented the group "normal glucose tolerance (NGT)" (plasma glucose <110mg/dl before glucose loading and <140 mg/dl after 120 min.), "IGT" (plasma glucose ≥140mg/dl and <200 mg/dl after 120 min.) and "diabetes mellitus(DM)" (plasma glucose ≥200mg/dl after 120 min.). We defined the subjects as pre-IGT if their plasma glucose is ≥180 mg/dl after 60 min. The OGTT results were follows: NGT 67(male15 / female52), pre-IGT 9 (m3 / f6), IGT 27 (m12 / f15) and DM 7(m5 / f2). Urinary myo-inositol(UMI) was calibrated by urinary creatinine(Ucre). We calculated ΔUMI as follows: ΔUMI(mg/gCre) =UMI/Ucre of 120min. - UMI/Ucre of 0min.
Results: ΔUMI was significantly associated with the plasma glucose response in OGTT. Estimated ΔUMI(mg/gCre) was follows; NGT(8.6±13.4), pre-IGT(26.7±18.9), IGT(27.6±30.0) and DM(97.0±48.4). The worse glucose intolerance, the higher ΔUMI would be expected. Based on the ROC curve, we set ΔUMI cut-off value as 10mg/gCre and compared the detecting ability of glucose intolerance among ΔUMI, A1C(≥6.2%) and urinary glucose excretion (≥100mg/dl after 120 min in OGTT). Within these three candidates, ΔUMI(≥10 mg/gCre) was the most powerful marker to isolate IGT. The positive rate of detecting glucose intolerance was follows; ΔUMI 69.8%, A1C 18.6% and urinary glucose excretion 55.8%.
Conclusion: We confirmed that ΔUMI derived from OGTT protocol is an effective marker to isolate glucose intolerance. We presume ΔUMI measurement could be an easy and cost-effective way in a community-based screening of glucose intolerance, since we need only urine samples, not blood, after oral glucose loading to calculate ΔUMI.

392

The association between IGFBP-1 and type 2 diabetes is modified by degrees of insulin sensitivity and early insulin response

C. Berne[1], A. Flyvbjerg[2], H. Grønbæk[3], K. Jensevik[4], L. Berglund[4], B. Zethelius[5];
[1]Department of Medical Sciences, Uppsala University, Sweden, [2]Department of Endocrinology and Internal Medicine, Clinical Institute, Aarhus University Hospital, [3]Medical Department V, Clinical Institute, Aarhus University Hospital, Denmark, [4]Uppsala Clinical Research Center, Uppsala University, [5]Department of Public Health and Caring Sciences /Geriatrics, Uppsala University, Sweden.

Background and aims: Clinical studies suggest that insulin-like growth factor binding protein 1 (IGFBP-1) may be an important determinant of glucose tolerance. Further, defects in insulin secretion and action are major abnormalities in type 2 diabetes (T2DM). Accordingly, we studied the relationship between serum IGF-I, IGF-II, IGFBP-1, IGFBP-3 and T2DM, taking into account insulin sensitivity (M/I) and the early insulin response (EIR).
Materials and methods: The participants were from a population-based cohort of 71-year-old men (n=1219) from which patients taking anti-diabetic oral medication or insulin were excluded. The cohort then underwent a 7-year follow-up (n=667). At baseline a euglycaemic insulin clamp and a 75-gram OGTT were performed. The concentrations of IGF-I, IGF-II, IGFBP-1 and IGFBP-3 were measured and their respective relationship with T2DM was assessed using logistic regression, presenting odds ratios (ORs) with 95% confidence intervals (CIs) for 1 SD increase in the predictor variable, adjusted for BMI and heredity for diabetes.
Results: The cross sectional associations with T2DM are presented in Table 1. The odds ratio for the association between IGFBP-1 and a low risk of T2DM was altered after adjustment for insulin sensitivity. IGF-I, IGF-II, IGFBP-1 or IGFBP-3 were not significantly associated with the risk for T2DM over 7 years of follow-up (p=0.14-0.90).
Conclusion: The association between IGFBP-1 and risk of T2DM is modified by EIR and insulin sensitivity implying confounding effects of insulin secretion and insulin resistance on the association, whereas it was not observed for IGF-II and the carrier proteins. The IGFs and their carrier proteins did not predict T2DM but were associated with the diabetic state.

Table 1. Cross sectional associations between IGF-I, IGF-II, IGFBP-1 or IGFBP-3 and T2DM

Variable	OR, 95 %CI, crude	OR,adjusted for EIR	OR,adjusted for M/I
IGF-I	1,36, 1,07-1,73	1,53, 1,18-1,99	1,28, 0.99-1,65
IGF-II	1,33, 1,05-1,70	1,42, 1,09-1,86	1,29, 1,02-1,64
IGFBP-1	0,71, 0,56-0,90	0,52, 0,40-0,68	1,23, 0.90-1,66
IGFBP-3	1,38, 1,07-1,77	1,52, 1,15-2,01	1,34, 1,03-1,74

393

The association between soluble urokinase plasminogen activator receptor (suPAR) levels and incident diabetes is modified by body weight status in high-risk people with impaired glucose regulation

T.M. Jensen[1], A. Heraclides[1], S.S.S. Rasmussen[2], J. Eugen-Olsen[3,4], S.B. Haugaard[3,2], K. Borch-Johnsen[1], A. Sandbaek[5], T. Lauritzen[5], D.R. Witte[1];
[1]Steno Diabetes Center, Gentofte, [2]Department of Endocrinology, Copenhagen University Hospital, Hvidovre, [3]Clinical Research Center, Copenhagen University Hospital, Hvidovre, [4]ViroGates A/S, Birkerød, [5]Department of General Medicine, University of Aarhus, Denmark.

Background and aims: An association between the inflammatory marker soluble urokinase plasminogen activator receptor (suPAR) and incident type 2 diabetes mellitus (T2DM) has been documented in healthy individuals. We aimed to assess whether this association exists among high-risk people with impaired fasting glucose (IFG) or impaired glucose tolerance (IGT) and whether it is affected by other risk factors for progression to diabetes.
Materials and methods: suPAR levels were measured in plasma samples from 1933 participants of the ADDITION study (aged 37-73 years) who had isolated IFG, isolated IGT or combined IFG/IGT at baseline (2001-2006) using the suPARnostic® ELISA kit (ViroGates, Denmark). Incidence of T2DM was ascertained by OGTT at 3 years of follow-up in combination with regular reports on glucose measurements in GP practice up to December 2008. The association between suPAR levels at baseline and incident T2DM was analyzed using logistic regression. Analyses were stratified by glucose regulation status (IFG, IGT, IFG/IGT) and BMI (lean, overweight, obese - WHO definition).
Results: Adjusting for sex and age, there was a 48% overall increase in risk of developing T2DM per 2-fold increase in baseline level of fasting suPAR (Table 1). The association was modified by body weight status, being limited to overweight participants. Additional adjustment for waist, blood pressure, lipids and smoking attenuated the association between suPAR levels and T2DM in the population as a whole; however, the association in the overweight group remained robust. Glucose regulation status did not modify the association.
Conclusion: suPAR levels are associated with incident T2DM in overweight individuals with impaired glucose regulation. Our finding of an absence of association among the obese may be due to the exclusion by design of those with diabetes at baseline, or may be caused by a difference in phenotype of obese subjects compared to overweight participants. This effect needs to be examined in greater detail in future studies.

Table 1. Odds Ratios for incident type 2 diabetes per each 2-fold increase in baseline suPAR level among 1933 participants of the ADDITION study.

		sex+age adjusted	sex+age+BMI*+ waist+ bp+ triglycerides+ HDL+ smoking
	No of cases/ total	**OR (95% CI)**	**OR (95% CI)**
Whole sample	599/1933	1.48. (1.12; 1.96)	1.24. (0.91; 1.69)
By glucose regulation status**			
i-IFG	186/800	1.36 (0.84; 2.21)	1.08 (0.63; 1.84)
i-IGT	175/652	1.56 (0.95; 2.56)	1.48 (0.85; 2.58)
IFG/IGT	238/481	1.28 (0.75; 2.16)	1.12 (0.63; 2.01)
By body weight status**			
Lean (BMI<25kg/m^2)	70/341	0.65 (0.31; 1.37)	0.61 (0.26; 1.41)
Overweight (BMI ≥25 <30kg/m^2)	231/806	2.36 (1.48; 3.76)	2.14 (1.31; 2.51)
Obese (BMI≥30kg/m^2)	298/786	1.12 (0.73; 1.73)	1.00 (0.63; 1.60)

*BMI included both as linear and quadratic term; Only waist circumference was used in the models stratifying by BMI

**p for interaction = 0.93 for glucose regulation status; 0.003 for body weight status

Leptin independently predicts diabetes in Swedish men

M. Lilja[1,2], O. Rolandsson[2], M. Norberg[2], P.W. Franks[2], S. Söderberg[2];
[1]The Research and Development Unit, Jämtland County Council, Östersund, [2]Departement of Public Health and Clinical Medicine, Umeå University, Sweden.

Background and aims: Leptin may have detrimental effects on the beta-cell function, and may decrease insulin sensitivity. Previous studies have shown an independent association between leptin levels and future diabetes in men, but not in women, whereas other studies have opposed these findings. The aim of this study was to evaluate leptin as an independent predictor of future diabetes in a northern Sweden setting.
Materials and methods: Within the Västerbotten Intervention Program (VIP), all inhabitants were invited to a health survey the year they turned 40, 50 and 60 years old. Questionnaires, blood sampling, measurements of anthropometry and blood pressure, and an oral glucose tolerance test (OGTT) were included. Through registries covering Västerbotten County, 638 subjects with type 2 diabetes were identified, who had participated in VIP prior (more than one year, mean 6.4 years) to diagnosis. A control group of 1564 non-diabetics, group matched for age, sex, region of residence and survey date within VIP was identified. Leptin was analysed with a RIA in stored samples. Logistic regression analysis was performed, and Odds Ratios (OR) and their 95 % Confidence Interval (95% CI) calculated. Leptin data are presented as quartiles with sex-specific cut offs based on the distribution amongst controls.
Results: In the univariate analysis, high leptin (Quartile 4 vs. Quartile 1) predicted diabetes in both men (OR 8.2 95% CI 5.2-13.0) and women (OR 6.4 95% CI 3.8-10.6, p_{trend} <0.0005). After adjustments for BMI, cholesterol, smoking habits, physical activity, education level and hypertension, leptin remained associated with diabetes in men OR 2.2 95% CI 1.2-3.9, p_{trend} 0.05). In separate models adjusting for BMI and adiponectin, diabetes heredity and fasting and 2-hour glucose levels from OGTT, or for a homeostasis model assessment (HOMA 2), leptin remained associated to future diabetes in men (p_{trend} <0.0005 for all).
Conclusion: Leptin independently predicts future diabetes in Swedish men, but not in women.

A novel method for the assessment of insulin physiology: urinary C-peptide creatinine ratio can be used to assess insulin sensitivity and beta cell function in non-diabetic subjects

A. Rawlingson, B.A. Knight, R. Oram, T.J. McDonald, B.M. Shields, A.T. Hattersley;
Peninsula NIHR Clinical Research Facility, Exeter, United Kingdom.

Background: Urinary C-peptide creatinine ratio (UCPCR) is a convenient, non-invasive measure of insulin secretion that is stable at room temperature for 3 days. It has been validated as a test of beta-cell function in type 1 and type 2 diabetes. The aim of our study was to test if UCPCR can be used to assess insulin sensitivity and insulin secretion in non-diabetic subjects under laboratory conditions and in the home setting.
Methods: We performed an oral glucose tolerance test (OGTT) using a standardised 75 g glucose load on 30 healthy volunteers (median age = 46 years; median BMI = 24.47). Serum insulin and C-peptide were measured on fasting blood samples and those taken at 30 min intervals for 120 min following glucose load and used to calculate insulin secretion and insulin resistance. UCPCR was measured on fasting urine samples and 120 min following glucose load. On a separate day, volunteers were asked to collect urine samples at home, 120 min following their largest meal of the day and post them to the laboratory.
Results: Fasting UCPCR correlated with HOMA-S (R=0.55; P<0.001). 120 min OGTT UCPCR correlated with serum insulin area under the curve (AUC) (R=0.69; P<0.001), serum C-peptide AUC (R=0.60; P<0.001) and early insulin secretion (R=0.41; P<0.05). Post-meal UCPCR correlated with 120 min OGTT UCPCR (R=0.55; P=0.01), serum insulin AUC (R=0.55; P<0.01), serum C-peptide AUC (R=0.53; P<0.05) and early insulin secretion (R=0.42; P=0.05).
Conclusion: In non-diabetic subjects, UCPCR measured in fasting urine samples and those collected following a glucose load or large meal are correlated with physiological measures of insulin sensitivity and insulin secretion. As urine samples are stable for 3 days at room temperature and can be collected by individuals at home, UCPCR is a convenient method for the assessment of insulin physiology that could be used in large scale epidemiological studies.

Sialic acid predicts incident cases of hospital-treated diabetes during 40 years of follow-up in a defined population: the Värmland Health Survey, Sweden

P. Khalili[1], F. Lundin[2], J. Jendle[1], I. Jungner[3], P. Nilsson[4];
[1]Faculty of Health Sciences, Örebro, [2]Värmland County Research Council, Karlstad, [3]Department of Medicine, Karolinska Institutet, Stockholm, [4]Department of Clinical Sciences, Malmö, Sweden.

Background and aims: Elevated inflammatory markers correlate with features of the metabolic syndrome and predict the development of type 2 diabetes. Sialic acid (SA) is related to glycoproteins and a marker of inflammation that has previously been associated with risk of coronary heart disease (CHD) events. We examined the role of SA in predicting incident hospital-treated cases of diabetes during 40 years of follow-up.
Materials and methods: A population-based health survey was carried out between 1962 and 1965 in the county of Värmland, Sweden. In total, 47,527 men and 48,124 women participated (mean age 48.9 and 48.6 years; range 25-80 years). The screening consisted of measurement of height, weight and blood pressure, as well as blood sampling including the determination of serum SA concentration. All subjects have been followed in national registers until end of 2005 for incident cases of hospital-treated diabetes mellitus (DM) as primary or secondary diagnosis. The material was sub-divided into quintiles (Q1-Q5) from lowest (Q1) to highest SA-levels (Q5). The risk of incident DM in relation to SA was analyzed by logistic regression separately for each sex. The association between baseline SA and risk of incident hospital-treated diabetes was analyzed by Cox proportional hazards regression before and after stepwise adjustment for baseline characteristics (age, BMI, hepatic transaminase GOT).
Results: During 40 years of follow-up, in all 4591 cases of diabetes treated in hospitals was recorded for men (9.7% of all men), and 5184 cases for women (10.8% of all women). The risk (OR) of incident DM in relation to SA-

quintiles for men was 1.0 in Q1 (reference), 1.19 (95% CI 1.08-1.30) in Q2, 1.20 (1.09-1.32) in Q3, 1.13 (1.02-1.25) in Q4 and 1.12 (1.02-1.24) in Q5. In women the corresponding OR was 1.0 in Q1, 1.24 (CI 1.12-1.36) in Q2, 1.31 (1.19-1.43) in Q3, 1.56 (1.42-1.71) in Q4 and 1.56 (1.45-1.74) in Q5. After full adjustment in the Cox-regressions, Exp (B) for one standard deviation of SA was 1.11 (95% CI 1.08-1.14) in men. The corresponding risk for women was 1.14 (1.11-1.17). P-values for all analyses were <0.0001.

Conclusion: The risk of incident diabetes mellitus in relation to high levels of sialic acid as an inflammatory marker is stronger in women than in men. The increased risk was independent of the other baseline characteristics.

PS 17 Epidemiology of type 2 diabetes mellitus and its complications

397

Cardiovascular risk factors and micro- and macrovascular complications in patients with type 2 diabetes in Italy

G. Pugliese[1], A. Solini[2], E. Bonora[3], E. Orsi[4], G. Zerbini[5], C. Fondelli[6], S. Morano[1], M. Cignarelli[7], L. Laviola[8], F.L. Cavalot[9], G. Gruden[9], R. Trevisan[10], M. Vedovato[11], A. Nicolucci[12], G. Penno[2];
[1]La Sapienza University, Rome, [2]University of Pisa, [3]University of Verona, [4]Fondazione IRCCS Cà Granda – Ospedale Maggiore Policlinico, Milan, [5]San Raffaele Scientific Institute, Milan, [6]University of Siena, [7]University of Foggia, [8]University of Bari, [9]University of Turin, [10]Ospedali Riuniti, Bergamo, [11]University of Padua, [12]Consorzio Mario Negri Sud, S.Maria Imbaro, Italy.

Background and aims: Type 2 diabetes mellitus (T2DM) is associated with increased morbidity and mortality for cardiovascular disease (CVD) and microvascular complications. This study aimed at assessing the prevalence of CVD risk factors and micro and macrovacular complications in patients with T2DM in Italy.

Materials and methods: We used baseline data from the Renal Insufficiency And Cardiovascular Events (RIACE) Italian Multicenter Study, a prospective cohort study on reduced estimated GFR as an independent predictor of CVD morbidity and mortality in T2DM subjects. The RIACE cohort consists of 15,773 T2DM patients consecutively visiting 19 Diabetes Clinics throughout Italy in years 2007-2008. Exclusion criteria were dialysis or renal transplantation. The following information was collected by a structured interview: age, gender, smoking status, diabetes duration, current therapy, and previous major acute CVD events. Height, weight, blood pressure (BP), HbA_{1c}, triglycerides (TG), total- and HDL- cholesterol (C), creatinine and albuminuria were measured, GFR was estimated using the 4-variable MDRD equation, and retinopathy was assessed with ophtalmoscopy or retinography

Results: Age was 66.0± 10.3 years, diabetes duration 13.2± 10.2 years, and male (M)/female (F) ratio 57/43. HbA_{1c} was 7.55±1.51%, with 24.2% and 40.9% below 6.5% and 7%, respectively; 61.4%% were on oral agents, 15.5% on insulin, and 9.6% on combined therapy. BMI was 28.96±5.14, with 41.9% overweight, and 24.4%. 8.4% and 3.3%, respectively, with grade I, II and III obesity. Waist was 103.7±12.7 cm, with 51.8% M below 102 and only 12.4% F below 88. TG, HDL-, LDL- and non-HDL-C levels were 139.2±88.2, 49.8±13.6, 107.7±32.6 e 134.9±36.8 mg/dl, respectively, with 68.3% on-target for TG, 50.7% of M and 56.8% of F for HDL-C, 42.1% for LDL-C and 48.3% for non-HDL-C; 46.2% were on lipid-lowering drugs and 42.5% on a statin. BP levels were 138.1±18.0 and 78.8±9.4 mmHg, with 43.5% and 73.1% with systolic and diastolic values <130 and 80 mmHg, respectively; 70.7% were on anti-hypertensive agents and 58.1% on RAS blockers. Current, former and never smokers were 15.3%, 28.1% and 55.6%, respectively. History of any CVD event was detected in 23.2%, myocardial infarction in 11.1%, stroke in 3.3%, foot ulcer/gangrene in 3.4%, and coronary, carotid and lower limb revascularization in 10.0%, 4.9% and 2.9%, respectively. Background and advanced retinopathy were detected in 12.5% and 9.6%, and micro and macroalbuminuria in 22.2% and 4.7%, respectively. Prevalence of GFR classes 1, 2, 3 and 4-5 as estimated by the MDRD formula was 29.6%, 51.7%, 17.1% and 1.6%, respectively. Of the 2,960 patients with chronic kidney disease, 56.6% were normo, 30.8% micro and 12.6% macroalbuminuric.

Conclusion: Results of this large-cohort study indicate a relatively good control of CDV risk factors and low prevalence of complications in Italian T2DM patients.

398

Diabetes duration: a crucial factor when determining individual target levels of glycaemic control in old age? (ZODIAC-20)

K.J.J. van Hateren[1], G.W.D. Landman[1], N. Kleefstra[1,2], I. Drion[1], K.H. Groenier[3], S.T. Houweling[2,4], H.J.G. Bilo[1,5];
[1]Diabetes Centre, Zwolle, [2]Langerhans Medical Research Group, Zwolle, [3]Department of General Practice, University Medical Center Groningen, [4]General Practice Sleeuwijk, [5]Department of Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: Studies regarding macrovascular consequences of glucose control in elderly patients (>75 years) with type 2 diabetes mellitus (T2DM) are lacking. This study aimed to investigate the relationship between HbA1c and (cardiovascular) mortality, and the role of diabetes duration in this relationship, in an elderly population.
Materials and methods: Between 1998 en 1999, 374 primary care patients older than 75 years with T2DM participated in the ZODIAC study, a prospective observational study. Data on mortality were collected in 2009. A Cox proportional hazard model was used to investigate the relationship between HbA1c as a continuous variable, as well as dichotomous variables (HbA1c <53 mmol/mol vs. HbA1c ≥53 mmol/mol, and HbA1c <48 mmol/mol vs. HbA1c ≥48 mmol/mol) and mortality. Analyses were performed in strata according to diabetes duration (<5 years, 5-11 years, and ≥11 years). Age, gender, smoking (yes or no), BMI, duration of diabetes, serum creatinine level, macrovascular complications (yes or no), albuminuria (yes or no), systolic blood pressure, total cholesterol-HDL ratio, and use of insulin (yes or no) were selected as possible confounders.
Results: In the group with a diabetes duration <5 years, the hazard ratios for HbA1c as a continuous variable were 1.40 (95%CI 1.14-1.73) and 1.66 (95%CI 1.25-2.21) for all-cause and cardiovascular mortality respectively. Within this patient group, a HbA1c level of <53 mmol/mol at baseline was associated with a reduced all-cause and cardiovascular mortality risk compared to patients with worse glycemic control. The hazard ratios were 0.56 (95%CI 0.33-0.95) and 0.28 (95%CI 0.11-0.69) respectively. Figure 1 illustrates the increased cardiovascular mortality rates for patients with a HbA1c level ≥53 mmol/mol. Glycemic control was not related to mortality for patients with a diabetes duration ≥5 years.
Conclusion: Worse glycemic control is related to increased mortality in elderly diabetic patients, but only in those with T2DM of short duration. Randomised controlled trials are necessary to answer the question whether improving glycemic control is beneficial in elderly patients. Perhaps different optimum target levels should be used for T2DM of short and long duration.

The role of cardiovascular risk factors in postmenopausal hypercholesterolemic women with abnormal fasting glucose: a post hoc analysis of the MEGA Study

T. Nakagami[1], R. Nishimura[2], H. Sone[3], N. Tajima[2];
[1]Diabetes Centre, Tokyo Women's Medical University School of Medicine, [2]Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, [3]University of Tsukuba, Mito Medical Centre, Department of Endocrinology and Metabolism, Ibaraki, Japan.

Background and aims: The incidence of cardiovascular disease (CVD) is increased in postmenopausal women, and the presence of CVD risk factors diminishes the favorable profile of women against CVD. Thus, understanding the role of CVD risk factors for CVD events and identifying effective interventions is important in postmenopausal women. The aim of this study is to assess the combined effect of CVD risk factors including abnormal fasting glucose (AFG) on the development of CVD in hypercholesterolemic postmenopausal women, and to evaluate the effect of low-dose pravastatin treatment, using the data from a large-scale clinical trial (MEGA Study).
Material and methods: The MEGA Study examined the effect of low-dose pravastatin (10-20 mg/day, approved dose in Japan) on primary prevention of CVD in 7,832 Japanese patients (5,356 women, post-menopause to 70 years; 2,476 men, 40 to 70 years) with mild to moderate hypercholesterolemia. Patients were randomized to diet alone (3,966 patients) or diet + pravastatin (3,866 patients) and followed for an average 5 years. AFG was defined as fasting plasma glucose (FPG) ≥6.1 mmol/L or anti-hyperglycemic agent users. Patients not having FPG value were excluded from this analysis (n=1,661). Normal fasting glucose (NFG) was defined as FPG <6.1mmol/L. Hypertension was defined by the attending physician as ≥140/90 mmHg, using the Japan Society of Hypertension guideline. The incidence of CVD in relation to age, hypertension, and AFG were compared between sexes. Hazard ratios (HRs) for incident CVD were calculated by using Cox's multivariable proportional hazards model, with the combinations of age, hypertension, and AFG, adjusted for treatment arm, high density lipoprotein cholesterol, and smoking.
Results: The incidence of CVD events was 2.3% (125/5,356) in women and 5.3% (130/2,476) in men. Table shows HRs for incident CVD for the eight possible combinations of the analyzed risk factors (age, hypertension, AFG). In women, compared to men, the risk for CVD was higher for each possible combination of age, hypertension and AFG, although no sex interaction was found for any risk factor combination due to small number of events. A similar risk reduction for coronary heart disease and cerebral infarction was found in the diet + pravastatin group compared to diet alone group (23% for women, p=0.39; 43% for men; p=0.03; interaction p=0.81).
Conclusion: The combining the older age and hypertension in AFG markedly increased the CVD risk in postmenopausal hypercholesterolemic women than men. Women with AFG may achieve a similar risk reduction for coronary heart disease and cerebral infarction with low-dose pravastatin as did men with AFG.

HRs for incident CVD for the combinations of age, hypertension, and AFG

Age ≥60y	HT	AFG	Men			Women

Peptic ulcers and inflammatory diseases of the upper digestive tract increase the risk of incident diabetes independently of obesity. The Whitehall II study

D.R. Witte[1], B. Carstensen[1], A.G. Tabák[2,3], C. Herder[4], M. Kivimäki[2];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]Epidemiology and Public Health, University College London, United Kingdom, [3]Semmelweis University, Budapest, Hungary, [4]Institute for Clinical Diabetology, Düsseldorf, Germany.

Background and aims: Recent interest in the effect of intestinal microflora and gastric bypass surgery on diabetes risk has highlighted the close connection between the gastro-intestinal (GI) system and glucose metabolism. We studied whether a diagnosis of upper GI peptic/inflammatory or ulcerative disease increased the risk of subsequent diabetes during up to 20 years of follow up.
Materials and methods: We studied 6766 participants of the Whitehall II study [69.7% men, mean age: 49.9 years (SD:6.0), BMI: 25.3 (3.7)] free of diabetes and GI diagnoses at baseline in 1991-1993. Participants were followed for incident diabetes with repeated OGTTs at 5-year intervals and self reports at 2.5-year intervals until December 2009. Hospital diagnoses were obtained from Hospital Episode Statistics data, covering all admissions to National Health Service hospitals in England. Participants with oesophagitis, gastritis, duodenitis, dyspepsia, gastro-oesophageal reflux or peptic ulcers of the oesophagus, stomach or duodenum (ICD-10 codes K20-K22, K25-K27, K29-K31) prior to diagnosis of diabetes or end of follow up were considered exposed. Their risk of incident diabetes was compared to the risk in those not exposed to an upper GI diagnosis using multivariate Poisson regression adjusting for relevant confounders.
Results: During a mean follow up of 16.9 years (total: 114,442 py), we observed 772 cases of incident diabetes (incidence rate: 8.0 per 1000 py) and 363 upper GI diagnoses. Mean time between GI diagnosis and DM was 5.5 years (SD: 3.3). The risk of diabetes increased after an upper GI diagnosis (Table 1). Adjustment for BMI, waist circumference, HDL cholesterol, triglycerides, fasting glucose and hs-CRP did not attenuate the effect. Models assuming that exposure starts with a 1-year lag after an upper GI diagnosis showed very similar results. The proportion of diabetes cases diagnosed through a study visit OGTT did not differ significantly between those with and without a GI diagnosis, indicating that detection bias is unlikely. Results were also consistent when examining oesophageal or gastric/duodenal diagnoses separately.
Conclusion: We found that peptic/inflammatory or ulcerative conditions in the upper GI tract increase the risk of diabetes by 10% per year in subsequent years independently of central and over-all obesity as well as other major risk factors for diabetes. Although baseline low grade inflammation did not explain our results, a later inflammatory response may play a role, in conjunction with alterations of the internal environment in the upper GI tract. Our results indicate that clinicians should be alert to the elevated risk of diabetes in patients with upper GI peptic/ulcerative diseases.

Table 1. Incidence rate ratio's (IRR) for the risk of diabetes after an upper GI diagnosis

Per year after diagnosis		
	IRR	(95% Confidence Interval)
Model A	1.08	(1.02;1.15)*
Model B	1.09	(1.03;1.16)*
Model C	1.10	(1.04;1.17)*
'Ever diagnosed'		
	IRR	(95% Confidence Interval)
Model A	1.69	(1.23;2.32)*
Model B	1.74	(1.27;2.40)*
Model C	1.85	(1.35;2.55)*

Adjustments: Model A: age and sex, Model B: A + BMI and waist, Model C: B + HDL-cholesterol, triglycerides, fasting glucose and hs-CRP. *: p-value <0.01.

401

Increased risk of acute renal failure in patients with type 2 diabetes compared to those without diabetes

K.G. Brodovicz[1], C.J. Girman[1], T.D. Kou[1], S.S. Engel[2], L. Katz[2], C.M. Alexander[3], D.E. Williams-Herman[2];
[1]Epidemiology, Merck, North Wales, [2]Metabolism, Merck, Rahway, [3]Global Medical Affairs, Merck, North Wales, USA.

Background and aims: Acute renal failure (ARF) is characterized by a rapid decline in glomerular filtration rate and can occur in patients with normal renal function as well as patients with pre-existing renal disease. ARF is a broad condition encompassing a spectrum of clinical renal dysfunction. While the natural history of a progressive decline in renal function from diabetic nephropathy has been well-described in patients with type 2 diabetes mellitus (T2DM), few studies have assessed the risk of ARF in a large population of T2DM patients. This study quantified the risk of ARF associated with T2DM in a large general practice database from the United Kingdom. In addition, the risk of ARF in T2DM patients with multiple comorbidities was assessed.
Materials and methods: Patients with T2DM (n=148,963) based on diagnosis, prescriptions or laboratory glucose and patients without diabetes (n=2,834,927) were identified from the General Practice Research Database. Patients with end-stage renal disease were excluded from the study. Crude incidence and age/gender-adjusted hazard ratios (HR) of ARF were estimated for T2DM and non-DM. Multivariate Cox regression models adjusted for risk factors including prior ARF, chronic kidney disease (CKD - including diabetic nephropathy), congestive heart failure (CHF), hypertension (HT), alcohol use, obesity, smoking, and Charlson comorbidity index. To assess potential additive effects, ARF risk was also assessed in patients with T2DM plus CHF and/or HT relative to patients without T2DM.
Results: Between 2003 and 2007, ARF incidence was 192 per 100,000 person-years (p-y) in patients with T2DM compared to 24/100,000 p-y among patients without T2DM (crude HR 8.3, 95% CI 7.7, 8.9). Age, obesity, prior ARF, CHF, CKD, HT, and comorbidity index were also higher in patients with T2DM. The risk of ARF for T2DM patients remained significant but attenuated in multivariate analyses adjusting for these factors (adjusted HR 2.4, 95% CI 2.2, 2.5). Adjusted ARF risk was also increased for patients with CHF (adjusted HR 2.2, 95% CI 2.0, 2.4), HT (adjusted HR 2.0, 95% CI 1.8, 2.2), and all of the above factors except CKD. Interestingly, the presence of CKD was not associated with an increased risk of ARF diagnosis (adjusted HR 1.25, 95% CI: 0.97 - 1.59). Adjusted ARF risk increased in T2DM patients with CHF and/or HT- T2DM with no HT/CHF: HR 2.3 (95% CI 2.1, 2.5), T2DM+HT (no CHF): HR 2.0 (95% CI 1.8, 2.3), T2DM+CHF (no HT): HR 4.5 (95% CI 3.7, 5.5), T2DM+HT+CHF: HR 3.5 (95% CI 2.7, 4.5).
Conclusion: Patients with T2DM have increased risk for ARF compared to patients without diabetes, even after adjustment for known risk factors including CKD. The finding that CKD alone is not associated with an increased risk of ARF diagnosis needs to be confirmed in other studies. The combination of T2DM, CHF, and HT further increased the risk for ARF relative to patients without T2DM. Physicians should be aware of this increased risk of ARF in T2DM patients, and the additional risk associated with the presence of other comorbidities such as CHF and HT.

402

Oral contraceptive use and abnormal glucose regulation in Swedish middle aged women

A. Deleskog, A. Hilding, C.-G. Östenson;
Molecular Medicine and Surgery, Stockholm, Sweden.

Background and aims: Use of oral contraception has been suggested to increase the risk of type 2 diabetes. Results of previous studies are however conflicting. The aim of this study was to investigate the association between oral contraceptives (OCs) use and abnormal glucose regulation in Swedish middle aged women.
Materials and methods: The present study includes 4794 women, aged 36-56 at baseline (1996-98), residing in five municipalities in Stockholm County Council and participating in the cross-sectional and follow-up study of Stockholm Diabetes Prevention Programme, which is a prospective population-based study. At both baseline and follow up 8 years later, the women were examined by oral glucose tolerance test (OGTT) classifying the subjects as having normal glucose tolerance, prediabetes (impaired fasting glucose (IFG), impaired glucose tolerance (IGT) or IFG+IGT) or type 2 diabetes. In addition, anthropometric measurements were collected and a questionnaire

was answered, including questions on lifestyle factors and use of OCs in different doses of estradiol and progesterone.
Results: In the cross sectional study, current use of OCs was associated with prediabetes, odds ratio (OR)=4.1 (95%CI: 2.2-7.8) but not with type 2 diabetes. The association to prediabetes was entirely linked to IGT, OR=7.1 (3.3-15.8) in current users of OCs and in former users, OR=2.1 (1.1-3.9). Women who used OC at baseline had a better cardiovascular risk profile with lower BMI, were more physically active and smoking was less common. At the follow up, the increased risk for prediabetes did not persist.
Conclusion: Current use of OC was associated with a four times increased risk of having prediabetes and seven times increased risk of having impaired glucose tolerance. No increased risk persisted at the follow-up, suggesting that the risk of prediabetes due to prior use of OC is decreasing with time. The healthier lifestyle in women who used OCs may have contributed to reduce the long-term risk of prediabetes.

403

Diabetic patient or patients with diabetes: an approach from comorbidity in primary health care

G. Mora Navarro[1], Á. Alberquilla Menéndez-Asenjo[1], P. Magán Tapia[2,3], M. Gil de Pareja Palmero[1], V. Del Saz Moreno[1], C. González Rodríguez-Salinas[2], M. Pilas Pérez[2], M. Ugalde Díez[2], P. Vallejo Sánchez-Monge[1], L. Rodríguez García[1], G. García Álvarez[1];
[1]11th Primary Health Care Area, Madrid, [2]Hospital Universitario 12 de Octubre, Madrid, [3]CIBER Epidemiología y Salud Pública, Barcelona, Spain.

Background and aims: To describe differences in burden of illness and variability in the Family Physicians management of patients with diabetes depending on their co-morbidity.
Materials and methods: Cross-sectional observational and descriptive study. Participans and settings: 129 family physicians selected by quality clinical records, attending 149417 patients during 2007. Computerized clinical record and pharmaceutical billing database: after grouping all patients with an episode of diabetes through case-mix ACGs System, the following indicators were built: chronic co-morbidities, consumption of visits, pharmaceutical consumption and referrals and standardized morbidity rate (SMR, using standard prevalence observed in all patients). To analyse variability of family physicians management of diabetes, two indicators were calculated for each family physician: Risk Index (RI) that relates the complexity of patients with the standard (if > 1, more complexity) and Efficiency Index (EI) that reports on the management of patients relating the consumption observed with expected, based on attended case-mix (if > 1, more consumption than expected). Variability indicators: coefficient of variation (CV), Extremal Quotient (EQ), excluding the outliers beyond of the 5-95 percentiles (EQ5-95) and of the 25-75 percentiles (EQ25-75)
Results: 10058 (6.7%) patients suffering from diabetes with an mean age of 66.7 years (SD 15.1), 52.6% were female. 9.7% of those with diabetes has no associates chronic co-morbidities and 41% had 3 or 4 and 34% 5 and more chronic co-morbidities. Most frequent pathologies were hypertension (61.2%), dyslipidaemia (44.5%), obesity (33,05%) and depression (21.5%). The correlation between the burden of illness and the number of visits, pharmacy and the number of referrals was R=0.99 (R^2=0.99), R=0, 99 (R^2=0.99) and R=0.97(R^2=0,94) respectively. SMR was higher than 1 for most of chronic diseases , especially hepatic chronic disease, skin ulcer, kidney chronic disease, chronic heart failure and coronary heart disease; and was lower than 1 for osteoporosis. Variability indicators using visits criterion was RI range: 0.7-1.2 (CV = 9% EQ5-95=1.4; EQ25-75=1.1) and EI range: 0.3-1.8 (CV=21% RV5-95=1.8; RV25-75=1.3) and using pharmaceutical consumption criterion RI range: 0.5-1.3 (CV=18%; EQ5-95=1.9; EQ25-75=1.3) and EI range: 0.9-3.3 (CV= 3% RV5-95=1.9; RV25-75=1.3).The correlation between RI and EI concerning visits consumption is R=-0.21 (R^2=-0.05) and pharmaceutical consumption R=-0.36 (R^2=0.13)
Conclusion: Most of diabetic patients has high associated co-morbidity, especially hypertension, dyslipidaemia, obesity and depression. Burden of illness seems to highly determine the impact of diabetic patients consumption on the National Health System. There is important variability in the family physician management of diabetic patients no related with complexity of case-mix.

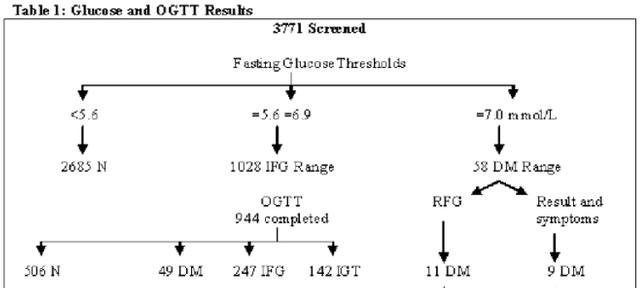
Prevalence of diabetes mellitus and pre-diabetes in an Irish cohort age 45-75 years

M. Sinnott[1], B. Carr[1], C. Walsh[2], P. O'Grady[1], G. Boran[3], B.T. Kinsley[4], J.J. Nolan[5];
[1]Vhi Healthcare, [2]Dept of Statistics, Trinity College Dublin, [3]Dept of Clinical Chemistry, Tallaght Hospital, [4]Dept of Endocrinology, Mater Hospital, [5]Dept of Endocrinology, St James's Hospital, Dublin, Ireland.

Backgrounds and aims: Type 2 diabetes (T2DM) and pre diabetes are preventable if known risk factors are identified and modified. To date there have been no large-scale studies of the prevalence of T2DM or pre-diabetes in Ireland. To address this issue the largest Irish health insurer, (covering over 62% of individuals with Private Medical insurance; 1.4 million members), has undertaken a study of the prevalence of undiagnosed T2DM and pre diabetes by screening 30,000 members. We report results from the first year of screening. To identify the prevalence of undiagnosed T2DM, impaired fasting glucose (IFG), impaired glucose intolerance (IGT) and diabetes risk in an Irish population.
Materials and methods: Members without a diagnosis of T2DM, aged 45 to 75 years living within 5 km of two major University Teaching Hospitals in Dublin, were chosen randomly and invited to participate. Participants completed a detailed medical questionnaire. Fasting plasma glucose (FPG), lipid profiles, blood pressure, weight, height, BMI, waist circumference, and waist: hip ratio were measured. Those subjects with initial FPG results of greater than or equal to 5.6 less than or equal to 6.9mmol/L had an Oral Glucose Tolerance Test (OGTT) performed. Those with an FPG greater than or equal to 7.0mmol/L had a repeat FPG performed. The Diabetes Risk Score was calculated based on FINRISK.
Results: 3771 participants (2125 female / 1646 male), were screened. Mean Age 60 ± 8.3 years (59.8 years ±8.2 for women; 60.2 years ± 8.3 for men). In the total screened group: T2DM = 1.8%, IFG = 6.5%, IGT = 3.8%. However among those subjects with an FPG between 5.6-6.9 mmol/L: T2DM = 5%, IFG = 26%, IGT =15 %. Glucose and OGTT results are summarised in the Table 1. Diabetes Risk Score results indicated that over 25 % of participants had a moderate or greater risk of developing T2DM (15 % women; 10 % men).
Conclusion: The prevalence of undiagnosed T2DM in the population screened to date is low, however over 10% of participants have pre-diabetes. Performing an OGTT as follow up on FPG 5.6-6.9 mmol/ identified either T2DM or pre diabetes in 46% of those tested. In conclusion screening for T2DM or pre diabetes is achievable in this setting, identifies unrecognised vascular and diabetes risk and could lead to disease prevention if the identified risk factors are modified.

Table 1: Glucose and OGTT Results



OGTT Results	Total Population	IFG Range: Initial F. Gluc. =5.6 =6.9	Initial Fasting Gluc. =5.6 =6.0	OGTTs Results (944)
DM	1.3%	5.0%	DM	1.6%
IFG	6.5%	26%	IFG	15%

Health-related quality of life: a marker of increased mortality in elderly type 2 diabetic patients (ZODIAC-18)

S.T. Houweling[1,2], K.J.J. van Hateren[3], G.W.D. Landman[3], K.H. Groenier[4], N. Kleefstra[2,3], H.J.G. Bilo[3,5];
[1]General Practice Sleeuwijk, [2]Langerhans Medical Research Group, Zwolle, [3]Diabetes Centre, Zwolle, [4]Department of General Practice, University Medical Center Groningen, [5]Department of Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: Diabetes-related complications and physical impairment are more prevalent in old age, and are likely to have detrimental effects on health-related quality of life (HRQOL). The aim of the present study was to assess the relationship between HRQOL and (cardiovascular) mortality, and the role of age in this relationship.
Materials and methods: Between 1998 en 1999, 1353 primary care patients with type 2 diabetes mellitus (T2DM) participated in the ZODIAC study, a prospective observational study. Early 2009, data on mortality were collected. HRQOL at baseline was assessed using the RAND-36 questionnaire. A Cox proportional hazard model was used to investigate the relationship between HRQOL and mortality. Analyses were performed in strata according to age: ≤ 75 years (n=979) and >75 years (n=374). The following variables were selected as possible confounders: age, gender, smoking (yes or no), systolic blood pressure, BMI, duration of diabetes, macrovascular complications (yes or no), albumin-creatinine ratio, serum creatinine level, total cholesterol-HDL ratio, and HbA1c.
Results: After a follow-up time of 10 years, 570 out of 1353 patients (42%) had died, of whom 280 deaths (41%) were attributable to cardiovascular causes. The Physical Component Summary (PCS) in both age groups was inversely related to all-cause and cardiovascular mortality (table 1; the hazard ratios refer to an increase of 10 points in the HRQOL scores). For the Mental Component Summary (MCS) an inverse relationship was observed only for patients aged 75 years of younger. Two separate RAND-36 dimensions were inversely related to all-cause and cardiovascular mortality in both age groups: physical functioning and general health perception.
Conclusion: Decreased HRQOL was related to increased all-cause and cardiovascular mortality in both younger and older patients with T2DM. These results are of special interest for elderly patients, since traditional risk factors become less predictive of mortality at higher age. HRQOL may be a useful tool to identify elderly patients at high-risk of mortality.

Hazard ratios of all-cause and cardiovascular mortality for PCS and MCS

RAND-36	All-cause mortality	Cardiovasular mortality
Physical Component Summary		
≤ 75 years	0.86 (0.80-0.93)	0.83 (0.73-0.93)
> 75 years	0.89 (0.81-0.96)	0.87 (0.76-0.98)
Mental Component Summary		
≤ 75 years	0.88 (0.81-0.95)	0.84 (0.74-0.95)
> 75 years	0.92 (0.85-1.00)	0.96 (0.84-1.08)

PS 18 Diabetes comorbidities: hospitalisation and cancer

406

Analysis of hospital admission causes in diabetic patients

P. Magán Tapia[1,2], Á. Alberquilla Menéndez-Asenjo[3], G. Mora Navarro[3], C. González Rodríguez-Salinas[1], V. Del Saz Moreno[3], M. Ugalde Díez[1], M. Gil de Pareja Palmero[3], M. Pilas Pérez[1];
[1]Hospital Universitario 12 de Octubre, Madrid, [2]CIBER Epidemiología y Salud Pública, Barcelona, [3]11th Primary Health Care Area, Madrid, Spain.

Background and aims: To describe the clinical features of diabetic patients who require hospital admission and the main reasons.
Materials and methods: Descriptive cross-sectional, observational study. Participants and settings: 584896 persons assigned to one of the Primary Health Care Centres attached to a reference hospital. From Primary Health Centres and hospital medical records, clinical data, number of admission and diagnostics that motivated during 2007 were registered. Hospitalization episodes were pooled using the patients DRGs (diagnostic related groups) classification system.
Results: 26845 patients were diabetics (4.6%), of which 10.6% (2840) had at least one admission. 51.6% of admitted were women and 52.2% of those who never was admitted during 2007, p = 0. 56. Admitted diabetic patients generated 4032 episodes of hospitalization, 1.4 admissions/patient (range 1-14). 61% was an emergency admission and the reason for discharge was recovery in 98.4%. Hospital death rate was 1.2%. The most common ICD-9 codes were coronary atherosclerosis 2.5%, congestive heart failure 2.0%, leg degenerative osteoarthritis 1.8% and intermediate coronary syndrome 1.6%. The admissions obtained by major diagnosis categories (MDC) distribution was 23.6% circulatory, 9.9% musculoskeletal, 9.6% respiratory and 9.2% digestive pathology. Episodes concerning endocrine, nutritional and metabolic were 4.6% of the cases. DRGs associated to diabetes appear only in 2.6% of hospitalisations. More frequent DRGs were respiratory disorders (3.4%) excluding infections, bronchitis and asthma complications or major co-morbidity, followed by two related heart failure DRGs (4.7%) Avoidable hospitalizations according to list of validated Ambulatory Care Sensitive Conditions (ACSC) for Spain diabetes codes were only 39 cases (0.97%) of this admissions group.
Conclusion: Cardiovascular pathology is the most usual cause of hospitalization in diabetic patients. Other complications of diabetes do not appear to be frequent admission reasons for patients with diabetes. A limited number of hospital admissions of diabetics are avoidable, which may reflect an appropriate management of diabetics in Primary Health Care.

The impact of diabetes mellitus in a tertiary hospital

P. Sousa[1], T. Brito[1], S. Pedro[2], S. Pereira[1], A. Lopes[1], E. Pina[1], V. Gomes[1];
[1]Hospital of Faro, [2]CEAUL & ESGHT, UAlg, Faro, Portugal.

Background and aims: The number of people with diabetes worldwide is set to double in the next 20 years. The impact of diabetes mellitus and associated co-morbidities on a tertiary Hospital is not completely understood. The aim of this study is to characterize the diabetic population admitted to our Hospital and analyze its evolution in the years 2000, 2005 and 2009.
Materials and methods: A retrospective, descriptive and correlational study, encompassing patients with diabetes (as primary or secondary diagnoses) admitted to a tertiary Hospital in the years 2000, 2005 and 2009 was performed. We evaluated age, gender, type of diabetes, cause of admission, length of stay, macrovascular complications, such as acute myocardial infarction and stroke and in-hospital mortality. Our results were compared with a national diabetes database**.** We used the International Classification of Diseases-9-Clinical Modification and the information provided by the local Medical Support System database. Statistical analysis of the data was performed using Statistical Package for Social Sciences 18. Inferential statistics (t test, ANOVA and X^2)was used to conduct an analysis of age, length of stay and in-hospital mortality predictors.
Results: The total patients admitted to our Hospital in these three years was 85588, 24635 in the year 2000, 30261 in the year 2005 and 30692 in the year 2009. In these years, 872 patients (4%), 1874 patients (6%) and 2205 patients (7%) had the diagnosis of diabetes, as primary or secondary, diagnoses in a total of 4951 diabetic patients (6%), 2624 (53%) male. The rate of diabetes as

a primary diagnosis was 14,3% and among these 30,6% were type 1 diabetes. We included patients of all ages (9 months - 100 years) with a mean of 69±16 years (2000: 68±16 years; 2005: 69±16 years; 2009: 70±16 years). In patients with type 1 diabetes the average age was 39±28 years and in patients with type 2 diabetes 69±15 years (p<0,001). Acute myocardial infarction was the primary diagnosis in 353 diabetic patients (7,1%) and stroke in 91 patients (1,8%). The average length of in-hospital stay of diabetic patients in the three years was 10±12 days. The average length of stay of type 1 diabetic patients was lower comparing with patients with type 2 diabetes (p=0,019). Age (p<0,001) and macrovascular complications (p<0,001) were also predictors of increased length of stay. Comparing the average hospitalization time between diabetic and non-diabetic patients, there was no significant difference (p=0,202) in year 2000. Inversely, there were significant differences in the years 2005 (p<0,001) and 2009 (p<0,001). The in-hospital mortality rate in diabetic patients was three times higher than that of non-diabetic patients (12% versus 4%, p<0,001). Age (p<0,001), diabetes as secondary diagnosis (p=0,013) and macrovascular complications (p=0,004), were predictors of higher mortality.

Conclusion:

1- The number of hospitalizations and the average age of diabetic patients, as primary or secondary diagnosis, have increased over a ten year period.

2- Patients with type 2 diabetes have a longer length of stay than patients with type 1 diabetes, probably related to their advanced age.

3- The average length of stay and in-hospital mortality in diabetic patients were higher comparing with national diabetes database.

4- This study suggests the need for a more aggressive intervention in the prevention, diagnosis and treatment of diabetes mellitus, reinforcing the need for optimal metabolic control for prevention of macrovascular complications.

408

Gender effect on the relation between diabetes and hospitalisation for heart failure

C. Seghieri[1], S. Nuti[1], G. Seghieri[2], F. Bardelli[2], F. Franconi[3];
[1]Scuola Superiore S.Anna, University of Pisa, [2]Dpt of Internal Medicine, Spedali Riuniti, Pistoia, [3]Dpt. of Pharmacology, University of Sassari, Italy.

Background and aims: Heart failure (HF) is a major cause for hospitalization especially in the elderly, and, at the same time, is mainly due to ischemic heart disease which, as well known, is strongly related to diabetes mellitus. It is likewise known that women are more protected than men toward the risk of cardiovascular diseases at least during the premenopausal period, while diabetes fully reverses such advantage, conferring to postmenopausal females a higher risk for cardiovascular complications and consequently HF. With such premises one can expect that gender difference is able to modify the association between diabetes and HF hospitalization, but no clear information so far exists about this point. More details on this point might be obtained by the availability of a wide centralized database containing all discharges across a given period of time from hospitals of a homogeneous region.

Materials and methods: To achieve this purpose we used a database concerning all hospital discharges from the wards of internal medicine (n=362,352M and n=385,806F) and of cardiology (n=91,411M and 49,212F) in Tuscany, Italy (3,686,377inhabitants) during the period 2002-2007 with a DRG derived from the corresponding ICD-9-CM codes of diabetes (250.xx) and/or of HF (DRG 127, containing ICD-9-CM codes 401.91, 402.01, 402.11, 402.91, 404.01, 404.3, 404.13, 404.93, 428.0, 428.1, 428.9) as main or secondary diagnosis. We considered discharges above age of 30 years due to the very low prevalence of HF below this age and calculated the relative risk and 95% CIs of being diagnosed diabetic in patients hospitalized for HF, stratified for age and sex.

Results: HF related hospitalization rate increased with age from 2.3% in the age group 30-39yr to 27.3% in the age group ≥90yr in men and from 1.1% to 30% in females, while diagnosis of diabetes progressively increased from the first decade to a maximum in age class 70-79yr (16.4% in men and 18.1% in females) and then decreased with further ageing in both sexes. The relative risk (95% CI) of HF hospitalization was about two-fold higher in diabetic than in non diabetic individuals across the entire observation period [1.97 (1.34-3.41) in males and 2.16 (1.60-3.53) in females]. The association diabetes-HF had a 'horse-shoe' pattern significantly raising in decade 30-39yr [2.27 (1.56-4.03)] (only in males), then reaching a maximum in class 40-49yr for males [3.24 (2.64-3.53)] and in decade 50-59yr for women [3.75 (1.94-4.03)], and afterwards progressively decreased, remaining more elevated in females during the entire period 40-69yr, and becoming equal in both genders during the following decades.

Conclusion: Hospitalization risk for HF was about two-fold higher in patients of both sexes with diabetes, being more elevated in females than in males in the life period ranging between 40 and 60 years, thus disclosing a risk peak linked to the existence of a 'perimenopausal effect'.

409

Glucose status in emergency medical admissions to one of the five busiest emergency hospitals in the Republic of Ireland

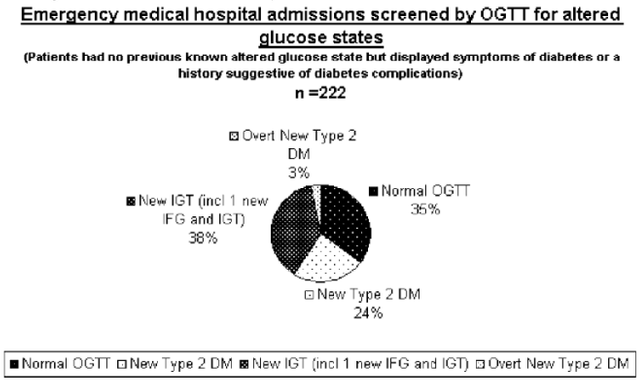
G.A. Roberts[1], D.B. Moore[1], K.T. O'Brien[1], S.E. Manley[2];
[1]Waterford Institute of Technology, Ireland, [2]Clinical Biochemistry, University Hospital Birmingham NHS Foundation Trust, United Kingdom.

Background and aims: Decreasing physical activity and increasing obesity of ageing populations in Western Europe contribute to increased incidence of impaired glucose tolerance (IGT) and diabetes mellitus (DM). Stress hyperglycaemia is common in acutely ill patients. Dysregulation of glucose is associated with increased morbidity / mortality and has major financial implications for healthcare. In this study, glycaemic status was determined in emergency medical admissions to the one of the five busiest emergency hospitals in the Republic of Ireland.

Materials and methods: During an 18 month time frame, an unselected 1237 (14%) of all 8659 emergency medical admissions were enrolled in the study. Patients with prior diagnosis of diabetes, impaired fasting glucose (IFG) or IGT were recorded. In the remaining patients, a 75g OGTT was performed on patients (18 years or older) who displayed symptoms of diabetes or a history suggestive of diabetes complications. OGTT glycaemic status was recorded according to WHO 2006 definitions.

Results: 270 of the sample admissions had previously diagnosed type 1, type 2 diabetes, or IGT. 6 new cases of type 1 diabetes were diagnosed at the time of admission without the need for OGTT. 719 sample admissions (58%) did not meet the inclusion criteria for performing the OGTT. 20 of the sample admissions were excluded from the OGTT due to age <18 years or known endocrine disease. OGTT was performed in the remaining 222 (18%) of sample admissions. All 222 were Caucasian with median age 71 years, IQ range 58 years to 81 years, 122 (55%) male. 55% were admitted due to cardiological illness, 12% due to neurological illness (including stroke or transient ischaemic attack) and 12% due to respiratory illness. 78 (35%) of OGTT screened patients were demonstrated to be normoglycaemic. 84 (38%) of OGTT screened patients demonstrated IGT and 53 (24%) demonstrated FPG or 2h-PG in the diabetic range. 144 (65%) of OGTT screened patients had abnormal glucose states that were previously undiagnosed representing 12% of the admissions sample. Adding to the 270 (22%) of admissions who had previously known abnormal glucose states, we demonstrated a minimum of 33.5% of emergency medical admissions that had abnormal glucose states.

Conclusion: This study indicates that 65% of patients admitted to one of the five busiest emergency admissions hospital of Ireland with symptoms of diabetes or its complications but not previously diagnosed with glucose dysregulation had impaired glucose tolerance or diabetes diagnosed by a OGTT during their stay. Whether this persists after their recovery needs to be ascertained, however there is still a considerable burden on diabetes services during their acute admission stay.



410

Elevated basal insulin increases the risk for total mortality in cancer incident subjects: The Israel Glucose Intolerance, Obesity and Hypertension 25-year Follow-Up Study

R. Dankner[1,2], A. Chetrit[1], C. Cohen[1], P. Segal[3];
[1]Unit for Cardiovascular Epidemiology, Gertner Institute for Epidemiology and Health Policy Research, Ramat Gan, [2]Epidemiology and Preventive Medicine, School of Public Health, Sackler School of Medicine, Tel Aviv, [3]Endocrinology, Sackler School of Medicine, Tel Aviv, Israel.

Background and aims: Type 2 diabetes has been associated with increased incidence, in the range of 1.2-2.5, for cancers of the liver, pancreas, endometrium, breast, colon, and bladder, and non-Hodgkin's lymphoma. Possible upstream factors, i.e. shared risk factors of diabetes and cancer, such as obesity, hyperlipidemia, and baseline hyperinsulinemia, have been suggested as explanations. The aim of this study was to investigate endogenous insulin as a risk factor in 25-year cumulative cancer incidence and as a prognostic factor among subjects who developed cancer.
Materials and methods: We followed cancer incidence and mortality in a sample of 1770 non-diabetic men and women, with mean age at baseline of 52.1+8.0, from 1980 until 2005. Baseline fasting, 1 and 2-hour post-load plasma glucose and insulin levels were recorded. All subjects were free of cancer at baseline. Cancer incidents occurring within the first 2 years of follow-up were excluded.
Results: During the follow-up period 327 individuals (18.5%) developed cancer (3.0%, 2.2%, and 2.7% developed breast, prostate, and colon/rectum cancers, respectively). Fasting insulin was not found to be significantly associated with overall cancer incidence, or with incidence of specific sites (breast, prostate, colon/rectum, or bladder). Median survival time for cancer patients in the upper fasting insulin quartile at baseline (>18.9 mU/L) was half that of those in the lower three quartiles: 4 years, 95%CI = 2-13 years, compared to 8 years, 95%CI = 6-15 years; p=0.1. In a Cox Proportional Hazard model, adjusting for age, sex, and ethnic origin, fasting insulin in the upper quartile conferred a 53% increased risk for total mortality (95%CI = 1.04 - 2.23) compared to the lower quartiles. Male sex, age, and ethnic origin were also found to be associated with a greater risk for mortality (p = 0.003, < 0.001, 0.03 respectively).
Conclusion: This long term cohort study suggests a role for elevated insulin levels in adulthood, not as a carcinogen, but as a factor adversely affecting cancer prognosis.

411

Diabetes is associated with an increased risk of cancer in the Canarian population

A. Arin Martínez[1], A. Cabrera de León[2], M.C. Rodríguez Pérez[2], D. Almeida González[2], B. Brito Díaz[2], J. Nóvoa[1,3], A. González Hernández[2], A.M. Wägner[1,4];
[1]Endocrinology Department, Complejo Hospitalario Universitario Insular Materno-Infantil de Gran Canaria, Las Palmas de Gran Canaria, [2]Research Unit, Hospital Universitario Nuestra Señora de Candelaria. Universidad de La Laguna., Santa Cruz de Tenerife, [3]Departamento de Ciencias Médicas y Quirúrgicas., Universidad de Las Palmas de Gran Canaria, [4]Departamento de Ciencias Médicas y Quirúrgicas, Universidad de Las Palmas de Gran Canaria, Spain.

Background and aims: While obesity has shown an association with most types of cancer, the association of diabetes with the disease is still controversial. The Canary Islands (Spain) have a high prevalence of obesity (32% of the adult population), diabetes (13%) and the metabolic syndrome (25.3%, according to the criteria of the International Diabetes Federation). Furthermore, some types of cancer are also increased in our population, especially breast cancer. The aim of this study was to assess the relationship between diabetes and the risk of cancer in the Canarian population.
Methods: A cross-sectional study was performed on the subjects enrolled in the "CDC (cancer, diabetes and cardiovascular disease) of the Canary Islands", a population-based cohort of 6729 individuals, aged 18-75 years, chosen randomly from the census of health care system affiliates (covering 99% of the population). Recruitment took place between 2000 and 2005. Clinical information was obtained using a questionnaire, anthropometric measurements were taken and blood samples were drawn. Diabetes was defined if the patient had a known diagnosis and/or received glucose-lowering treatment. In the absence of information confirming the diagnosis, diabetes was defined by fasting glucose concentrations above 125 mg/dl on two separate occasions. Cancer was self-referred and confirmed with data obtained about hospital admissions and treatment prescriptions. The risk of cancer was compared between 6721 subjects (8 were lost due to absence of reply) with and without diabetes (chi-squared, Yates' continuity correction). In order to adjust for possible confounders, a multiple logistic regression analysis was performed, including the overall risk of cancer as the dependent variable and age, gender, body mass index, years of smoking and parental history of cancer as independent variables. A p value below 0.05 was considered significant.
Results: Information was available for analysis from 6721 subjects of the cohort. The overall prevalence of cancer was 1.8%: 3.9% among the diabetic and 1.5% among the non-diabetic subjects (OR 2.604 [95% CI 1.694-4.002], p<0.0005). After adjustment for possible confounders, the association between diabetes and cancer remained significant (OR 1.633 [1.034-2.579], p=0.036). Gender (OR 0.511 [0.327-0.797], p=0.004 for males), age (OR 1.067 [1.048-1.086] per year, p<0.0005) and maternal history of cancer (OR 2.391 [1.598-3.579], p<0.0005) were also associated with cancer in this model, whereas years of smoking, body mass index and paternal history of cancer were not.
Conclusions: Diabetes is associated with an increased risk of cancer in the Canarian population, independently of age, gender, body mass index, smoking and parental history of cancer.

Diabetes and cancer in Mauritius

D.J. Magliano[1], S. Söderberg[1,2], P. Zimmet[1], S. Kowlessur[3], V. Pauvaday[3], J.E. Shaw[1];
[1]Population and profiling, Baker IDI Heart and Diabetes Institute, Melbourne, Australia, [2]Department of Public Health and Clinical Medicine, Cardiology, Umeå University Hospital, Sweden, [3]Ministry of Health and Quality of Life, Port Louis, Mauritius.

Background and aims: Although evidence supporting the association of diabetes with cancer risk is growing, there are no data on diabetes and cancer in South Asian and Africans populations. The aim of this work was to explore the relationship between diabetes, impaired glucose tolerance (IGT) and impaired fasting glycaemia (IFG) and all-cause and site-specific cancer mortality adjusted for conventional risk factors in a large multi-ethnic cohort living in the developing nation of Mauritius.
Materials and methods: Population-based surveys were undertaken in Mauritius in 1987, 1992 and 1998 (n= 9559). Participants were aged 18 years or greater and 66%, 27%, and 7% were of South Asian (Indian), African (Creole), and Chinese descent, respectively. Response rates for all surveys were greater than 85%. Questionnaires, anthropometric measurements, and a 2 hour 75-g oral glucose tolerance test were undertaken at each survey. Glucose tolerance was classified according to World Health Organisation 1999 criteria. In 2007, a mortality follow-up was undertaken. Cox's proportional hazards model with age as the time scale was used to obtain hazard ratios (HRs) for risk of all-cause cancer and site-specific cancer mortality, adjusted for sex, smoking, prior CVD, ethnicity, hypertension, education, waist and hip circumference, and leisure time physical activity.
Results: Over a median follow-up of 15.1 years, there were 1559 deaths (199 due to cancer), 7168 survivors and 832 participants were lost to follow-up. After exclusion of deaths in the first year after baseline, compared with those with normal glucose tolerance (NGT), the all-cancer mortality HRs (95% confidence intervals (CIs)) for known diabetes mellitus (KDM), newly diagnosed diabetes mellitus (NDM), impaired glucose tolerance and impaired fasting glycaemia were 2.34 (1.19 to 4.59), 1.80 (1.00 to 3.26), 1.34 (0.73 to 2.46) and 0.80 (0.28 to 2.25) in men and 1.19 (0.63 to 2.22), 0.58 (0.26 to 1.33), 1.34 (0.80 to 2.27) and 0.53 (0.13 to 2.22) in women, respectively. In men, but not women, total cancer mortality risk increased with rising plasma levels of postload glucose - HR for the top versus bottom quintile was 2.52 (1.34 to 5.59), Ptrend <0.025 in fully adjusted models. There was no relationship between fasting plasma glucose and total cancer mortality in either sex. The HRs for breast and reproductive tract cancer mortality for women with diabetes (KDM and NDM) compared to women without diabetes were 2.67 (0.95 to 7.67) and 1.09 (0.28 to 4.26) in South Asians and Africans, respectively after adjustment for age, smoking and waist circumference.
Conclusion: This is the first study in a developing country of the impact of glucose intolerance on cancer mortality in an African or South Asian population. The independent association of diabetes (KDM and NDM) and post-

load glucose with total cancer mortality risk in men in this study provides first time evidence of such a relationship in Africans and South Asians. These results are important in a global context for future health policy in the light of the impact of the rapid increase in prevalence of diabetes and cancer, especially in developing nations.

413

Chronic hepatitis B infection increased risk of all site cancer in type 2 diabetic patients with suboptimal glycaemic control

R.C.W. Ma, W.-Y. So, A. Luk, L.W.L. Yu, A.P.S. Kong, C.C. Chow, P.C.Y. Tong, X. Yang, J.C.N. Chan;
Dept of Medicine and Therapeutics, Chinese University of Hong Kong, China.

Background and aims: Over 10% of people in China have chronic HBV infection and type 2 diabetes (T2DM). Both of these chronic conditions have been implicated in carcinogenesis. We hypothesized that chronic HBV infection may interact with poor glycaemic control to increase risk of cancer in type 2 diabetes.
Materials and methods: In a prospective cohort from the Hong Kong Diabetes Registry (HKDR) consisting of 4205 T2D patients with known HBV status and detailed documentation for risk factors, complications, treatments and clinical outcomes followed up for a mean period of 6 years, we examined the incidence of cancer in patients stratified by A1c and explored their interactions with HBV carrier status. Cox proportional hazard regression was used to obtain hazard ratios (HRs) of HBV infection for cancer in univariable models and multivariable models. To test possible interactions between HBV infection and hyperglycaemia for cancer, we separately performed initial checking of the HRs of HBV infection for the risk of cancer among patients with A1c<7.4% and among those patients with A1c≥7.4% in univariate and multivariate models. We further examined biological interaction of HBV infection and hyperglycaemia (i.e., A1c≥7.4%) using: 1) Relative excess risk due to interaction (RERI); 2) Attributable proportion due to interaction (AP); and 3) Synergy index (S).
Results: HBV carriers have increased risk of cancer (HR 1.70; CI: 1.28-2.25, p<0.0001). When divided according to HbA1c, the hazard ratios of all-site cancer was 2.23 (CI: 1.57-3.16; p<0.0001), after adjustment of other clinical attributes. Interactive models suggest the increased risk of cancer in HBV carriers is present among subjects with HbA1c ≥7.4%. Analysis using the RERI, AP or S index revealed there was statistically significant biological interaction between HBV carrier status and HbA1c ≥ 7.4 mmol/L for the risk of cancer in Type 2 diabetes.
Conclusion: In type 2 diabetic patients with suboptimal glycemic control, the coexistence of chronic HBV infection substantially increased the risk of cancer. The rapid transition from communicable to noncommunicable diseases in China will have major implications on morbidity and mortality including cancer.

Risk factors for pancreatic cancer aetiology of glucose intolerance

L. Czupryniak[1], A. Gasiorowska[2], R. Talar-Wojnarowska[2], E. Szymanska-Garbacz[1], M. Pawlowski[1], M. Saryusz-Wolska[1], A. Borkowska[1], E. Malecka-Panas[2], J. Loba[1];
[1]Internal Medicine and Diabetology Department, Medical University of Lodz, [2]Digestive Tract Diseases Department, Medical University of Lodz, Poland.

Background and aims: Relationship between the incidence of pancreatic cancer and the development of diabetes is unclear. Diabetes has been suggested to be a risk factor for pancreatic cancer. On the other hand, glucose intolerance or frank diabetes is often the first sign of a pancreatic cancer, a fatal disease unless diagnosed at a very early stage. However, at present with diabetes being so prevalent, cancer etiology of glucose intolerance might be easily missed, bringing fatal consequences upon a patient. We studied glucose tolerance in patients with newly diagnosed pancreatic cancer aiming at identifying factors suggestive of cancer etiology of glucose metabolism disturbances. The additional aim of the study was to assess endothelial dysfunction and subclinical inflammation as markers of cardiovascular risk, often neglected in this group of patients.
Materials and methods: The study group was 18 non-diabetes individuals with newly diagnosed pancreatic cancer (PC group) (mean age 69.6±8.9 years, BMI 23.0±4.7 kg/m2); 13 age- and body weight-matched healthy subjects served as controls. All subjects underwent oral glucose tolerance test (OGTT) according to WHO protocol with plasma glucose and insulin measurements. HOMA index and fasting plasma adiponectin, TNF-alfa, interleukin-6 (IL-6), interleukin-1beta (IL-1b), sE-selectin, thrombomodulin, soluble adhesion molecules sICAM and sVCAM, and high-sensitive CRP were assessed.
Results: PC and control subjects plasma glucose values in OGTT were at 0 min 98±21 and 90±17, 60 min - 166±43 and 103±36 (p<0.01), 120 min - 173±39 and 90±28 (p<0.001) mg/dl, and plasma insulin at 0 min 3.6±1.8 and 10.2±7.9 (p<0.01), 60 min - 22.3±17.4 and 33.1±21.4, 120 min - 31.9±19.3 and 34.1±44.7 mIU/l. PC patients presented also with significantly greater insulin sensitivity as measured with HOMA than the controls (0.83±0.39 vs 2.34±1.87; p<0.01). Moreover, PC subjects as compared with the controls had significantly greater plasma adiponectin (16132±8165 vs 6681±4329 ng/ml; p<0.001), IL-6 (8.6±4.9 vs 3.9±1.4 pg/ml; p<0.01), thrombomodulin (2.0±0.8 vs 1.1±0.5 ng/ml; p<0.01), sICAM (929±417 vs 318±85 ng/ml; p<0.001) and sVCAM (1669±489 vs 857±312 ng/ml; p<0.001).
Conclusion: Individuals with newly diagnosed pancreatic cancer present with elevated post-challenge plasma glucose associated with significant insulin sensitivity. Diagnosing glucose metabolism disturbances in lean subjects with high insulin sensitivity should point at the possibility of pancreatic cancer as an underlying condition. Moreover, despite absence of insulin resistance, newly diagnosed PC subjects present with clinical markers of subclinical inflammation and endothelial dysfunction.

PS 19 Early mechanisms in autoimmune diabetes - animal models

An experimental study showing dietary gluten as triggers of type 1 diabetes

J.T.J. Visser[1], K. Lammers[2], A. Fasano[2], H. Harmsen[3], G. Welling[3], F. Stellaard[4], N. Bos[4], J. Rozing[1];
[1]Cell Biology, Section Immunology, University Medical Center Groningen, Netherlands, [2]Mucosal Biology Research Center, Baltimore, USA, [3]Medical Microbiology, University Medical Center Groningen, [4]University Medical Center Groningen, Netherlands.

Background and aims: Type 1 diabetes (T1D) is a multifactorial autoimmune disease and besides genetic susceptibility several environmental factors such as diets and gut microbiota contribute to the onset of the disease. Recent epidemiological data indicate that T1D incidence in Europe might double around the year 2020. Genetic factors cannot explain this dramatic increase, which indicate that changes in environmental factors are mainly responsible. There is accumulating evidence that dietary gluten might be important dietary triggers of T1D. Epidemiological data show that early introduction of dietary gluten increases the chance to develop T1D. Also aberrant immune responses against wheat gluten have been found in T1D patients. In this study we investigated in the diabetes prone (DP)BB rat animal model for T1D whether dietary gluten can modulate diabetes development and potential mechanisms involved such as changes in gut microbiota composition, intestinal barrier function and (innate/mucosal) immune status.
Materials and methods: BBDP rats were fed specific diets with different amounts of gluten. One group received the hydrolysed casein (HC) diet. The HC-diet is gluten free and the proteins are degraded to small fragments leading to the loss of diabetogenic epitopes. The other groups received the HC-diet with 2%, 4% and 10% gluten respectively. The control group received the standard diet with ±4% gluten. Rats were followed for T1D development and feces, gut tissue, lymph-nodes and blood were collected. Because gluten can affect intestinal permeability, BBDP rats were subjected to a Lactulose Mannitol (LA/MA) test to measure intestinal permeability in vivo. Composition of gut microbiota was established in the feces by qPCR.
Results: Addition of 10% gluten to the HC-diet completely abrogated the diabetes protective effect of the HC-diet. HC-fed rats (n=21), 50% diabetic median age 85 days vs HC+gluten fed rats (n=14), 90% diabetic median age 76 days ($p<0.05$, log rank test). Moreover, addition of 10% gluten also completely reversed the HC-diet induced improved intestinal barrier function as shown by a 2-fold increased urinary LA/MA levels ($p<0.05$, MWU test) and a trend for a reduced ileal expression of claudin-1 mRNA ($p<0.1$, MWU test). We have shown previously that the HC-diet lowers intestinal *bacteroides* levels of BBDP rats. Yet, the gut microbiota composition of HC fed rats did not differ from HC+gluten fed rats. High levels of anti gliadin antibodies were found in sera of HC+gluten fed rats, indicating systemic immune activation. Effects of gluten on (innate/mucosal) immune status are now under investigation.
Conclusion: Gluten are potent dietary triggers of T1D. Manipulating intestinal barrier function and (innate/mucosal) immune activation might be important mechanisms for this effect. Better insight in how dietary gluten can induce T1D development will lead to dietary intervention strategies in order to reduce the chance to develop T1D in people at risk.

Rapid influx of macrophages into peritoneal cavity of NOD mice after weaning suggests increased permeability to gut bacteria

A.L.M. Hänninen, C. Alam, S. Valkonen;
Medical Microbiology and Immunology, University of Turku, Finland.

Background and aims: Increased gut permeability has been proposed as an important mechanism of sensitization against T1D-related autoantigens in gut immune system. The distal part of gut also contains a large ecosystem of microbes, which are important in creating the right balance of helper-T-cell subsets for gut immune responses. Our recent findings indicate an excess of Th17 cells and other inflammatory cells in colons of young NOD mice. The aims of this study were to investigate if this inflammation leads to extra-intestinal manifestations such as increased peritoneal cell numbers, and any signs of bacterial leakage from the gut.
Materials and methods: Peritoneal leukocytes in NOD and BALB/c mice were counted and phenotyped using trypan blue, flow cytometry and real-time PCR. Presence of bacteria was investigated with PCR using primers for bacterial 16S-RNA. IL-1β, IL-6 and IL-12 were analyzed using qt-PCR.
Results: In peritoneum of 4,5 week-old NOD mice total number of macrophages was 3.0(±0.43)x10E6 compared to 0.76(±0.23)x10E6 in BALB/c mice and 0.68(±0.51)x10E6 in NOD mice fed antidiabetogenic Prosobee-diet ($p < 0,001$, one-way ANOVA). At the same age, bacterial 16S-RNA PCR revealed the presence of bacterial DNA in peritoneum of 3/20 NOD mice compared to 0/20 BALB/c mice (N.S.). In all 3 cases, sequencing identified the presence of the same bacterial species in NOD peritoneum. The excess of macrophages did not associate with increased production of proinflammatory cytokines in the peritoneum compared to BALB/c mice.
Conclusion: Shortly after weaning, there is a rapid "influx" of macrophages into peritoneum of NOD mice which is prevented by antidiabetogenic diet. Simultaneously, bacteria may gain access to extra-intestinal locations. This may stimulate the innate arm of systemic immune responses and break tolerance to autoantigens.

Daintain/AIF-1 plays important role in the initiation and progress of type 1 diabetes

Z.-W. Chen[1,2], X.-Y. Huang[1], W. Wang[1], Y.-Y. Zhao[1];
[1]College of Life Science and Technology, Wuhan, China, [2]Department of Molecular Medicine, Karolinska Hospital, Stockholm, Sweden.

Background and aims: Type 1 diabetes (T1D) is characterised by progressive destruction of pancreatic beta cells as a consequence of infiltration by mononuclear cells and lymphocytes. The early stage of the disease process is termed insulitis. The beta cell death in the course of insulitis is suggested to be caused by direct contact with activated macrophages and T-cells, and/or exposure to soluble mediators secreted by these cells, including cytokines, nitric oxide (NO), and oxygen free radicals. The molecular mechanisms for the pathogenesis of T1D are still incompletely understood. Daintain/AIF-1, as an inflammatory factor, is secreted by macrophages and T cells. We have previously demonstrated a densely accumulative daintain/AIF-1 immunostaining in the pancreas of BB rats, an animal model of T1D, when they were suffering from insulitis. The aim of the present study was to further investigate the roles of daintain/AIF-1 in the pathogenesis of T1D.
Materials and methods: Studies were performed in NOD mice, an animal model of T1D, using immunoprecipitation, Western blots, immunohistochemistry, Total Internal Reflection Fluorescence Microscope (TIRFM), flow cytometry, and affinity chromatography.
Results: Using immunoprecipitation followed by Western blot, we found that daintain/AIF-1, as a circulating protein, exists in the blood of non-diabetic Balb/c and diabetic NOD mice, but the plasma concentration in NOD mice was distinctly higher than in age-matched Balb/c mice (40 ug/L vs 10 ug/L, $p < 0.001$), which suggests that daintain/AIF-1 associates with T1D. We also found that daintain/AIF-1 immunostaining appeared in the pancreas of NOD mice when they already suffered with T1D, and no insulin was detected in the pancreas of those animals, indicating that daintain/AIF-1 may be involved in beta cell death in T1D. When daintain/AIF-1 was intravenously injected into NOD mice (100ug/25 g body weight, 3 times in other 10 days), the white blood cell proliferation in the mice was largely increased (4.5×10^9/L vs 1.7×10^9/L, $p < 0.001$), indicating that daintain/AIF-1 is able to promote inflammation in the mice. In parallel, the plasma concentration of insulin was gradually decreased and the plasma glucose concomitantly increased. Finally, using immunocytochemistry it was also found that the beta cells were undetected, but the alpha cells existed in the pancreas, which suggests that daintain/AIF-1 selectively damage beta cells. Using TIRFM and flow cytometry, we found Daintain/AIF-1 is able to infiltrate into the primary pancreas beta cells and damage the cells *in vitro*. With affinity chromatography and followed by peptide mass fingerprinting, a kind of Daintain/AIF-1-interacting proteins was identified as cystathionine beta-synthase (CBS) from the mice pancreas. CBS is involved in the metabolism of homocysteine, the later is a risk factor for damaging tissues, and beta cells are very sensitive to homocysteine.
Conclusion: Taken together, these results indicate that daintain/AIF-1 plays important roles in the initiation and progress of T1D. Daintain/AIF-1 will be a novel target molecule for prevention and treatment of T1D.

Previous Coxsackievirus B3 infection in mothers protect offspring from virus-induced type 1 diabetes

P.G. Larsson, M. Flodström-Tullberg;
Center for Infectious Medicine, Dept. of Medicine, HS, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Type 1 diabetes (T1D) results from the destruction of the pancreatic insulin-producing beta cells. It is a complex autoimmune disease involving both genetic and environmental risk factors. Epidemiological studies and clinical observations point to an association between T1D and enterovirus infections, in particular those with Coxsackie B virus serotypes (CVBs); Enteroviruses have been identified in and isolated from the pancreas of newly diagnosed T1D patients. Moreover, enterovirus RNA has been more frequently found in serum from recent-onset T1D patients than in serum from healthy controls. Despite the strong association between enterovirus infections and T1D, recent studies in different human populations (countries) have suggested that the presence of enterovirus infections in the background population shows an inverse relationship with the population incidence of T1D. This counterintuitive finding has lead to the suggestion that enterovirus infections may have a more severe impact in populations where infections occurr less frequently (a.k.a. the poliovirus hypothesis). Indeed, low background herd immunity to a pathogen may lead to more severe disease in infected individuals. This may in part be due to a reduced transfer of maternal antibodies to offspring (passive immunity). To date there has been no attempts to experimentally test this hypothesis. Thus, the aim of this study was to establish a model in which we could determine whether maternally transferred antibodies protect genetically susceptible offspring from enterovirus-induced T1D.
Materials and methods: The present study used the SOCS-1 transgenic NOD model (SOCS-1 Tg NOD) that develops T1D rapidly after infection with CVB3 and CVB4, and non-tg NOD mice that do not develop T1D upon infection with these viruses. NOD females were infected intra-peritoneally (i.p.) with an immunizing dose of CVB3 (10^2 pfu). After the acute infection was cleared, infected and uninfected females were bred with SOCS-1-Tg NOD males, progeny was challenged i.p. with a diabetogenic dose of CVB3 (10^3 pfu). Diabetes development was monitored by daily blood glucose measurements. Neutralizing antibodies were quantified by a serum neutralization assay.
Results: Immunized NOD females (n=3) had CVB3-neutralizing antibodies in the serum (p<0,001, vs. uninfected controls, n=4). The majority of SOCS-1-transgenic offspring from uninfected mothers developed T1D after infection (83%, n=10/12). In contrast, only approximately half (54%, n=13/24) of the transgenic offspring from immunized mothers developed T1D (p=0,14).
Conclusion: Preliminary observations suggest that passive immunization via the transfer of antibodies from the mother protects offspring from virus-induced T1D. These results support the extended poliovirus hypothesis as an explanation for the reported inverse correlation between the observed number of enterovirus infections and the incidence of T1D in a population. These studies may also have important implications for the development of an effective therapy to protect neonates from enterovirus infections. Our findings indicate that vaccination of women before childbirth could be an efficient therapy to prevent enterovirus infections in progeny, and thereby possibly also virus-induced T1D.

Apoptosis resistance of non-obese diabetic mouse thymocytes is mediated by a defective p53 expression and altered microRNA network controlling cell death and proliferation

N. Tormo-Badia, C. Bolmeson, M. Carlsén, A. Makowska, S. Ahmad, C.M. Cilio;
Clinical Sciences, Lund University, Malmö, Sweden.

Clonal deletion during negative selection in the thymus is fundamental in order to establish central tolerance and to avoid the development of autoimmune disorders such as type 1 diabetes (T1D). It has been previously shown that NOD thymocytes display a defect in the establishment of central tolerance as well as and resistance to cell death when exposed to apoptosis inducing agents. However, the underlying mechanisms contributing to these traits are still elusive. The tumour suppressor gene p53 has been demonstrated to be involved in thymocyte apoptosis and is up-regulated in response to DNA damage and during thymocyte selection. Our aim was to study the molecular basis of apoptosis resistance of NOD thymocytes and to understand whether this process could be involved in diabetes pathogenesis in NOD mice. Here we were able to show that NOD mice are unable to up-regulate p53 and caspases 1 and 11 after γ-irradiation compared to wild type C57BL/6 mice. Recently, it has been shown that p53 is regulated by the microRNA (miRNA) family miR-34. We found a decreased expression of mir-34a and mir-34b/c in NOD thymocytes in response to DNA damage. Sequencing of the miR-34 gene family revealed 3 significant polymorphisms in the miR-34a gene in NOD mice. Interestingly, one of the nucleotide variant in NOD miR-34a gene is located in close proximity to a p53 binding site. The miR-34a gene is located in the mouse *Idd-9.2* diabetes susceptibility locus, and the miR-34b/c genes are clustered in the *Idd2*-locus. Thus, the miR-34 genes represent potential candidate genes for diabetes development in NOD mice. In conclusion, our results highlight the molecular basis for thymocytes apoptosis resistance observed in NOD mice, which might ultimately predispose to the development of autoimmune diabetes.

MafA is a key regulator of insulin expression in the thymus

S. Noso[1], K. Kataoka[2], Y. Kawabata[1], N. Babaya[1], Y. Hiromine[1], K. Yamaji[3], T. Fujisawa[3], H. Ikegami[1];
[1]Department of Endocrinology, Metabolism and Diabetes, Kinki University School of Medicine, Osaka-sayama, [2]Laoratory of Melecular and Developmental Biology, Nara Institute of Science and Technology, Ikoma, Nara, [3]Department of Geriatric Medicine, Osaka University Graduate School of Medicine, Suita, Japan.

Background and aims: Tissue-specific self-antigens are ectopically expressed within the thymus and play an important role in the induction of central tolerance. Abnormal regulation of the intra-thymic expression of a certain self-antigen is therefore expected to cause organ-specific autoimmune disease. Insulin is expressed in both pancreatic islets and the thymus, and is considered to be the primary antigen for type 1 diabetes. Here, we report the role of insulin transactivator MafA in the expression of insulin in the thymus and susceptibility to type 1 diabetes.
Materials and methods: The expression profiles of transcriptional factors (*Pdx1*, *NeuroD*, *Mafa* and *Aire*) in pancreatic islets and the thymus were examined in NOD (non obese diabetic) and control mice(C3H mice). The nucleotide sequence of *Mafa* was identified by direct sequencing in NOD, C3H, Balb/c, CTS and NSY mice. Luciferase reporter assay was performed for newly identified promoter polymorphisms of NOD *Mafa* sequences .
Results: *Mafa*, *Ins2* and *Aire* expression was detected in the thymus. *Mafa* expression was significantly lower in NOD thymus than control, and was correlated with *Ins2* expression(R^2=0.809). When the data were stratified by strain, the correlation was stronger in control (R^2=0.863) than in NOD mice (R^2=0.393). No correlation was found between *Ins2* and *Aire* in either control C3H (R^2=0.145) or NOD mice (R^2=0.135). The entire nucleotide sequence of mouse *Mafa* was identical among the control strains (Balb/c, C3H and CTS mice) and an animal model of type 2 diabetes (NSY mice). Only NOD mice showed variation in the nucleotide sequence of *Mafa* compared to other strains. NOD *Mafa* promoter activity was significantly lower than that of wild type by 27% (p<0.0001).
Conclusion: These data suggest that MafA is a key regulator of insulin expression in the thymus, and functional polymorphisms of *Mafa* are newly identified in the NOD mouse.

Altered leukocyte recruitment during inflammation in type 1 and type 2 diabetes models

U.S. Pettersson, S.M. Santos, G. Christoffersson, L. Jansson, J. Henriksnäs, M. Phillipson;
Dept. of Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Diabetes is often associated with a systemic low-grade inflammation, the origin of which is uncertain. Despite the low-grade inflammation, diabetic patients are known to have an impaired bacterial clearance. To fight an infection, leukocytes need to leave the circulation at the afflicted

site, which occurs through regulated steps of activation and interactions of endothelium and leukocytes. The effect of hyperglycemia on leukocyte function is a matter of debate. The aim of this study was to evaluate leukocyte recruitment in established models of inflammation during high- and moderate hyperglycemia.
Materials and methods: The experimental models of diabetes used in the current study were induced either by i.v. administration of alloxan, causing a severe hyperglycemia, or by a high fat diet, causing a moderate hyperglycemia. In anaesthetized diabetic or control C57Bl/6 mice, the number of adherent and emigrated leukocytes was studied using intravital microscopy of the exposed cremaster muscle before and during exposure to the chemokine MIP-2. Bacterial clearance in alloxan- or untreated mice was studied after a subcutaneous injection of luminescent *S. aureus* using a non-invasive IVIS camera system, and the fraction of recruited leukocyte subtypes was analyzed at different time points post infection.
Results: During basal conditions, prior addition of chemokines, both severe and moderate hyperglycemia resulted in increased numbers of adherent and emigrated leukocytes compared to normoglycemic mice. In response to MIP-2 addition, the number of emigrated cells was significantly increased in severely hyperglycemic mice compared to control mice. However, alloxan-treated mice demonstrated decreased number of recruited leukocytes after 5 and 10 days post infection and an impaired ability to clear bacterial infections compared to control mice.
Conclusion: In conclusion, in both alloxan-, and high fat diet-induced diabetes, leukocyte recruitment was increased in untreated as well as chemokine exposed cremaster muscles, indicating that acute hyperglycemia activated leukocytes and/or endothelial cells. However, the ability to clear bacterial infections was reduced in alloxan-treated mice due to fewer amounts of recruited leukocytes later in the recruitment process.

Metabolic phenotypes in preclinical autoimmune diabetes in man and mouse: pathways behind progression to overt disease
M. Oresic[1], M. Sysi-Aho[1], A. Ermolov[2], P. Gopalacharyulu[1], T. Seppänen-Laakso[1], O. Simell[3], M. Knip[4], S. Kaski[2], E. Savontaus[3]; [1]VTT Technical Research Centre of Finland, Espoo, [2]Aalto University School of Science and Technology, Espoo, [3]University of Turku, [4]University of Helsinki, Finland.

Background and aims: The incidence of type 1 diabetes among children and adolescents has increased markedly in the Western countries during the recent decades and is presently, for unknown reasons, increasing at a faster rate than ever before. Recent evidence from serum metabolomics indicates that specific characteristic metabolic disturbances precede β-cell autoimmunity markers and accurately identify those children who subsequently progress to diabetes. The causes and tissue-specific mechanisms leading to these early metabolic disturbances are unknown.
Materials and methods: A total of 70 mice (26 female) were monitored weekly with serum collection from age 3 weeks until either (a) the development of diabetes and then followed by treatment with insulin for 4 weeks (progressor group), or (b) followed until 36 weeks of age in females and 40 weeks in males in the absence of a diabetic phenoptype (non-progressor group). Global lipidomics using UPLC/MS was applied on all 1172 samples, and a biomarker for diabetes prediction in 8 week old female mice was developed based on insulin autoantibody (IAA) level and the lipidomic profile. Computational statistical modeling was applied to compare and align the longitudinal lipidomic profiles of NOD mice with the profiles of children who later developed diabetes. In an independent experiment normoglycemic female NOD mice were sacrificed at 8 (n=57) or 19 (n=14) weeks of age and blood, liver and pancreas samples were collected. The mice were stratified according to high or low risk of developing diabetes based on lipidomics-derived serum marker. Additionally, lipidomics, metabolomics (GCxGC-TOFMS) and transcriptomics were applied to isolated islets and liver.
Results: The specificity of the pre-autoimmune metabolic changes identified in serum lipidomes of human type 1 diabetes progressors, as indicated by their conservation in murine model of type 1 diabetes. We show that young female non-obese prediabetic mice who later progress to autoimmune diabetes exhibit the same lipidomic pattern than prediabetic children, and that these changes are accompanied by dysregulation of specific metabolic and immunoregulatory pathways in pancreatic islets and liver. Specifically, plasma insulin, insulinotropic amino acids in islets, and pathways of liver insulin signaling were already significantly upregulated in those prediabetic mice at high risk of developing diabetes. The pathogenic relevance of these metabolic pathways is further suggested by the observation that insulin autoantibody positive mice, that were protected from diabetes, had reduced mitochondrial pathways including OXPHOS in the islets.
Conclusion: The findings indicate that autoimmune diabetes is preceded by a state of islet increased metabolic demands resulting in elevated insulin secretion and suggest alternative metabolic related pathways as potential therapeutic candidate targets.

Depletion of IL-2/15 receptor beta-positive cells protects from diabetes in non-obese diabetic mice: role of natural killer cells and a subset of CD8+ T cells

H. Brauner[1], S. Johansson[1], H. Hall[1], M. Flodström-Tullberg[2], K. Kärre[1], P. Höglund[1];
[1]Microbiology, Tumor and Cellbiology, [2]Center for Infectious Medicine, Dept. of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden.

Background and aims: A role for natural killer (NK) cells in type 1 diabetes has been suggested, but the literature is conflicting. We have recently shown NK cells with unique phenotypic and functional properties in the pancreas of NOD mice. This project aims at elucidating a possible role of NK cells in type 1 diabetes (T1D) by applying in vivo depletion of NK cells in non-obese diabetic (NOD) mice using the monoclonal antibody TMβ1.
Materials and methods: TMβ1 is a monoclonal antibody directed against the beta chain of the murine IL-2/15 receptor (CD122). CD122 is highly expressed on all NK cells and on a small subpopulation of CD8+ T cells in the spleen. 200ug of the antibody to CD122 (TMβ1) was given i.p. once weekly to NOD mice and urine glucose measured. The effect on NK cells and T cell subsets were investigated in the pancreas, spleen and draining pancreatic lymph nodes (PLN). In order to investigate the presence and phenotype of pancreatic lymphocytes without contamination of lymphocytes from blood or lymph nodes the mice were flushed with PBS via the heart and lymph nodes removed under microscopy. The effect of TMβ1 treatment on lymphocyte infiltration into the pancreas was also explored using immunohistochemistry. NK cell function after TMβ1 treatment was assessed in vivo as the elimination of fluorescently labelled MHC class I-deficient spleen cells. The influence of TMβ1 treatment on primary CD8+ T cell responses was studied as IFNg production following immunization with the non diabetogenic antigen GP33. The TMβ1 effect on priming in the draining lymph nodes was investigated in an adoptive transfer model where BDC2.4 transgenic CD4+ T cells bearing a diabetogenic TCR were labelled with cells labelled with the fluorescent dye CFSE and transferred to NOD mice treated with TMβ1 or PBS. CFSE distributes equally in divided cells, and was used to measure proliferation after 3 days.
Results: In vivo administration of the TMβ1 antibody to non-obese diabetic (NOD) mice protected against diabetes development when administered just before disease onset. Depletion removed all NK cells and most CD122-expressing CD8+ T cells in the spleen. Some CD8+ T cells in the pancreas also disappeared despite lack of CD122 expression, suggesting either an indirect effect of NK cells, or reduced trafficking of CD122+ peripheral T cells to the pancreas. NK cell function is totally abolished after TMβ1 treatment whereas specific CD8+ T cell responses remain unaltered and the levels of the activation marker CD69 is unchanged on T cells both in the pancreas, spleen and PLN. Preliminary results suggest that TMβ1 treatment does also not affect the proliferation of T cells in the PLN. The possibility that the cytokine production may be altered in these proliferating T cells is being investigated. A detailed immunohistochemical analysis of the infiltrating lymphocytes is also currently ongoing.
Conclusion: We propose that targeting of CD122+ cells may represent a novel treatment strategy against late events in type 1 diabetes. With only minor effects on the immune system this treatment could prolong the disease free period, or even prevent disease onset, in patients at risk of developing type 1 diabetes.

Efficient gene transfer to the pancreas using adeno-associated viral vectors for prevention of type 1 diabetes in mice

A. Casellas[1,2], V. Jimenez[1,2], E. Ayuso[1,2], J. Agudo[1,2], M. Obach[1,2], A. Salavert[1,2], S. Muñoz[1,2], M. Moya[1,2], X. Leon[1,2], M. Molas[1,2], D. Ramos[3,2], J. Ruberte[3,2], F. Bosch[1,2];
[1]CBATEG and Department of Biochemistry and Molecular Biology, School of Veterinary Medicine, Universitat Autonoma de Barcelona, Bellaterra, [2]CIBER of Diabetes and Associated Metabolic Disorders, Barcelona, [3]CBATEG and Department of Animal Health and Anatomy, School of Veterinary Medicine, Universitat Autonoma de Barcelona, Bellaterra, Spain.

Background and aims: Gene therapy may provide new treatments for severe pancreatic disorders. However, gene transfer to the pancreas is difficult because its anatomic location and structure, and pancreatitis is a serious concern. We have previously shown that pancreatic beta cells can be transduced to express marker genes after systemic injection of first generation adenovirus (FGAd) in mice with clamped hepatic circulation. However, FGAd are not suitable for long term effects because the immune system recognizes and eliminates transduced cells due to the expression of viral genes. Here we investigated whether adeno-associated viral vectors (AAV), which lack all viral genes, are low immunogenic and capable of long-term expression, were able to mediate efficient gene transfer to the pancreas.
Materials and methods: AAV serotypes 6, 8 and 9 carrying GFP as a marker gene or murine hepatocyte growth factor (mHGF) were generated by triple transfection in 293 cells and were purified by double cesium chloride gradient. AAV vectors were administered into the pancreatic duct through the sphincter of Oddi while the choledoc was clamped close to the liver edge.
Results: The intraductal injection of several doses of AAV6, AAV8 and AAV9 vectors coding GFP resulted in an efficient transduction of the exocrine and endocrine pancreas. The number of transduced acinar cells increased in a dose dependent manner and AAV9 was the most efficient serotype transducing these cells. Transduction of ductal cells was only observed when AAV6 was administered intraductally. AAV6, AAV8 and AAV9 vectors administered via the pancreatic duct transduced beta cells in the periphery of the islets. Moreover, beta cells in the periphery and in the core of the islets showed high expression of the marker gene when high doses of AAV6, AAV8 and AAV9 were administered to the pancreas. However low percentage of alpha cells were transduced by AAV serotypes 6, 8 and 9. Furthermore, the intraductal administration of AAV9 vectors coding mHGF resulted in partial prevention of T1D in a transgenic animal model of diabetes.
Conclusion: These results show that AAV administration via the pancreatic duct is an efficient approach for genetic manipulation of the pancreas. This approach could be used to study islet and pancreas physiology and also to assay new gene therapy approaches for Diabetes Mellitus and other pancreatic disorders.

Administration of an IL-1 trap counteracts type 1 diabetes in NOD mice

T. Rydgren, A. Börjesson, S. Sandler;
Medical Cell Biology, Uppsala, Sweden.

Background and aims: We previously reported that the addition of IL-1 traps (hybrid molecules consisting of the extracellular domain of IL-1 receptor accessory protein and IL-1 receptor type 1 arranged inline and fused to the Fc-portion of IgG1) to rat pancreatic islets *in vitro* can protect against noxious effects induced by IL-1β as well as a cytokine combination. In this study we tested the effect of administration of a murine IL-1 trap on the recurrence of disease (ROD) model in non obese diabetic (NOD) mice.
Materials and methods: Spontaneously diabetic female NOD mice received implantation of a curative number (600) of syngeneic pancreatic islets, from young healthy NOD mouse donors, beneath their left kidney capsule. Once a day, the mice were injected subcutaneously with IL-1 trap (30 mg/kg bodyweight), or an equimolar dose Fc-control protein (8.4 mg/kg bodyweight) or saline. The treatments were maintained until ROD (i.e. a blood glucose value >11.1 mM for 2 consecutive days) or until 5 days after transplantation. Data are presented as means ± SEM.
Results: Analysis of cumulative islet graft survival revealed that mice treated with IL-1 trap had an increased graft survival (14.1 ± 3.2 days) compared to mice treated with Fc-control protein (5.6 ± 1.0 days) ($p<0.05$), when compared with the Kaplan-Meier survival curve and Logrank test, and a trend for prolonged graft survival compared to saline treated mice (7.6 ± 0.9 days) ($p=0.076$). Analysis of relative cytokine mRNA levels in isolated spleen cells, retrieved after both endpoints, showed elevated IL-4 mRNA levels in cells from mice treated with IL-1 trap, compared to both control groups (endpoint ROD: Saline 0.0072 ± 0.0008, Fc-protein 0.0101 ± 0.0019, IL-1 trap 0.0239 ± 0.0063*, endpoint 5 days post tx: Saline 0.0059 ± 0.0009, Fc-protein 0.0042 ± 0.0004, IL-1 trap 0.0142 ± 0.0041* ($2^{-\Delta CT}$), n=5-7, *=$p<0.05$ vs. both Saline and Fc-protein treated animals using one way ANOVA with subsequent all pair-wise comparison procedures by Student-Newman-Keuls method). This suggests a shift toward Th2 cytokine production in the IL-1 trap treated animals, which may contribute to its protective effect.
Conclusion: Administration of an IL-1 trap counteracts islet cell destruction in this recurrence of disease NOD mouse model of type 1 diabetes.

Ciliary neurotrophic factor prevents, delays and ameliorates type 1 diabetes in Swiss, C57Bl6 and iNOS-/- mice

L.F. Rezende, G.J. Santos, E.M. Carneiro, A.C. Boschero;
Anatomy, Celular Biology and Physiology and Biophysics, Institute of Biology, State University of Campinas, Brazil.

Background and aims: CNTF is a cytokine known for its survival effects in many cell types, including rat pancreatic islets. Type 1 Diabetes (DM1) is characterized by a selective loss of pancreatic islet beta-cell mass and subsequent hyperglycaemia, a condition that can be induced by Multiple Low Doses of Streptozotocin (STZ), a model (MLDS) that resembles human Type 1 Diabetes. The Nitric Oxide (NO) production and Inducible Nitric Oxide Sintase (INOS) expression role on the DM1 onset and progression have been controversial. Given CNTF beta-cell protection against apoptosis, we decided to evaluate the effects of CNTF in a Type 1 Diabetes model that resemble the human disease (MLDS), and since CNTF was described to increase INOS expression and NO production, we assessed whether or not its effects on DM1 would be hampered in a INOS Knockout mice.
Materials and methods: For MLDS, 4-6 weeks-old Swiss, C57Bl6 or INOS-/- mice were administered by intra-peritoneal injection once daily for 5 consecutive days using saline injection as control (C), 40mg/Kg of STZ for MLDS group (S) 40mg/Kg of STZ plus 0.1 mg/Kg of CNTF for CNTF group (N). We assessed mice fed glycaemia in days -3, 0, 1, 3, 7, 14, 21, 28 and 35 after the first injection. Type 1 diabetes considered as blood glycaemia >250 mg/dl for 2 days. We evaluated mice overall glycaemia, Type 1 diabetes incidence, severity and time until occurrence. Furthermore, we evaluate INOS mRNA expression in MIN6 cells cultured for 3 days in the absence (CTL) or presence 0.1nM, 1nM or 5nM of CNTF by RT-PCR (n=16). Data=Mean +-SEM. $P<0.05$.
Results: In all strains (Swiss, C57Bl6 and iNOS-/-), CNTF-treated mice had an overall lower glycaemia than STZ-group and a lower Type 1 diabetes incidence, although it was more pronounced in the C57Bl6 one. Even among those that developed diabetes in CNTF group, it took them longer to occur and was less severe than the STZ group. CNTF increased INOS expression in MIN6 cells in a dose-dependent manner, but even so, its protective effects against DM1 in INOS-/- strain were similar to those observed in the wild-type C57BL6.
Conclusion: The results indicate that CNTF protects against STZ-induced Type 1 Diabetes, even in INOS-/- mice strain. Given that CNTF increased MIN6 cells INOS expression in a dose-dependent manner, the CNTF protective effects were not mediated trough or hampered by the increased INOS expression, and the functional importance of this increase in INOS expression by CNTF in mice beta-cells is yet to explained. Lastly, we can conclude CNTF could be a potential therapeutic tool in the prevention or even early treatment of DM1 patients.

Induction of regulatory CD8 T cells after diabetes manifestation by treatment with a rat specific CD3 antibody in the IDDM rat as a tool for protection of pancreatic beta cell function

T. Arndt, S. Lenzen, A. Jörns;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and aims: In human type 1 diabetic patients the residual function of the beta cells, measured by C-peptide, can be restored by treatment with CD3-antibody (AB) for up to one year. Interestingly, in humans it was found that the number of regulatory CD8 T-cells in the blood was increased after therapy with CD3-AB. In this study we treated IDDM (LEW.1AR1-iddm) rats, an animal model of type 1 diabetes mellitus (T1DM), immediately after diabetes manifestation with CD3-AB in analogy to the human therapy. The aim of the study was to analyse changes of the immune cell subpopulations in the blood and pancreas draining lymph nodes of animals treated with CD3-AB in comparison to acutely diabetic animals without therapy and normoglycaemic rats.
Materials and methods: To secure beta cell function after diabetes manifestation, acutely diabetic IDDM rats were treated with CD3-AB (Clon R73 0.5 mg/kg b. wt.) consecutively over 5 days. The effect of the CD3-AB therapy and changes in the immune cell subpopulations were analysed by flow cytometric analysis in the blood and by real time PCR analysis of isolated T-cells from pancreas draining lymph nodes. The infiltration stages of the pancreatic islets in CD3-AB treated IDDM rats were compared to normoglycaemic IDDM rats and diabetic rats without treatment.
Results: In prevention therapy with CD3-AB, initiated directly after diabetes manifestation, the reduction of all T-cells can be monitored by flow cytometric analysis. FoxP3 positive T-cells, especially CD8 T-cells, increased within one week of therapy. The increased number of regulatory CD8 T-cells induced by CD3-AB therapy was observed in all treated IDDM rats in comparison to acutely diabetic rats even though the efficacy of the prevention therapy with CD3-AB was dependent of the metabolic state of the diabetic IDDM rats before start of treatment. Only animals with a blood glucose concentration up to 13 mmol/l at the start of the therapy could be completely cured. After therapy the number of pancreatic beta cells increased in the islets of these animals whereas the signs of immune cell infiltration were less reduced in comparison to the diabetic animals without treatment. Even after a complete clinical remission of diabetes, a certain immune cell infiltration remained in the islets.
Conclusion: Interestingly, analogues to the findings in type 1 diabetic patients under CD3-AB therapy, the IDDM rats showed also an increased number of regulatory CD8 T-cells in the blood. This indicates that the IDDM rat is a very good model to analyse the function of regulatory T-cells in the context of CD3-AB treatment to modulate the imbalance of the immune cells during diabetes development by an increase of regulatory T-cells.

428

Comparison of two type 1 diabetes prevention therapies of a CD3 antibody in combination with FTY720 or a TNF-α antibody on beta cell function in the IDDM rat, an animal model of type 1 diabetes

A. Jörns[1], M. Akin[1], G. Ertekin[1], A. Meyer zu Vilsendorf[2], T. Taivankhuu[1], S. Lenzen[1];
[1]Institute of Clinical Biochemistry, [2]Department of Visceral- and Transplantation Surgery, Hannover Medical School, Germany.

Background and aims: The IDDM (LEW.1AR1-*iddm*) rat is an animal model of type 1 diabetes mellitus without lymphopenia and therefore very suitable for evaluation of combined immunomodulatory therapies. The aim of the CD3-antibody (AB) treatment in combination with the immunomodulatory agent FTY720 or the TNF-α-AB was to protect the remaining pancreatic beta cells from autoimmune destruction after onset of the disease. The CD3-AB interacts with the T-cell receptor to inhibit cytokine production and release from T-lymphocytes, while the sphingosin-1-phosphate receptor antagonist FTY720 retains the lymphocytes in the organ draining lymph nodes and the TNF-α-AB blocks the released TNF-α.
Materials and methods: Animals were treated with CD3-AB (0.5 mg/kg body weight) in combination with either TNF-α-AB (1 mg/kg b. wt.) consecutively over 5 days or over 40 days with FTY720 (1 mg/kg b. wt.). Besides the metabolic changes, pancreatic biopsies at the time point of diabetes manifestation, at the end of therapy, and 60 days after the end of therapy were analysed for beta cell survival and immune cell infiltration by ultrastructure as well as on the gene and protein expression level.
Results: Prevention therapy with both combinations starting immediately after disease manifestation with blood glucose concentration values between 10 - 15 mmol/l reversed clinical diabetes leading to normoglycaemia during and after therapy. Morphologically, beta cells in the islets during and after therapy showed a fivefold reduced apoptosis rate and a threefold increased islet beta cell area. Both CD8 T-cells and CD68 macrophages were markedly decreased in the islets at the end of therapy and nearly completely lost 60 days later. The small amount of immune cells surrounding the islets and in the capillary system of the islets lost the pro-inflammatory cytokine expression after therapy. In both combined therapies with the immunomodulatory agents the remaining beta cells in the islets were ultrastructurally well preserved without signs of destruction. The only difference between both combination therapies was the higher amount of macrophages in and around the islets after CD3- and TNF-α-ABs-therapy.
Conclusion: Combined therapy of CD3-AB with FTY720 or with TNF-α-AB showed a great benefit with respect to the survival of pancreatic beta cells with a normalized apoptosis rate in islets without immune cell infiltration in comparison to the initial small number of beta cells and the high apoptosis rate in the severely infiltrated islets before the start of the therapy. The beneficial effects of both strategies could be maintained also after the end of the therapy.

PS 21 Islet autoantibodies in type 1 diabetes

429

Combined measurement of autoantibodies against GAD, IA-2, insulin and ZnT8 in the Diabetes Autoantibody Standardization Program 2009 Workshop

M. Schlosser[1], P.W. Mueller[2], V. Lampasona[3], A.J.K. Williams[4], P. Achenbach[5];
[1]Department of Medical Biochemistry and Molecular Biology, Ernst-Moritz-Arndt University Greifswald, Karlsburg, Germany, [2]Centers for Disease Control and Prevention, Atlanta, USA, [3]Center of Genomics, Bioinformatics and Biostatistics, Milano, Italy, [4]Clinical Science at North Bristol, University of Bristol, United Kingdom, [5]Diabetes Research Group of the TU Munich, Germany.

Background and aims: The Diabetes Autoantibody Standardization Program (DASP) is a collaboration between the Immunology of Diabetes Society and US Centers for Disease Control and Prevention, set up to evaluate and improve assays for type 1 diabetes (T1D)-associated autoantibodies (AAb). The DASP 2009 workshop aimed to assess the sensitivity/specificity and concordance of assays measuring AAb to GAD (GADA), IA-2 (IA-2A), insulin (IAA), and zinc transporter 8 (ZnT8A) in laboratories throughout the world. We assessed the combined detection of these four AAb in DASP serum samples considering differences in assay performance.
Materials and methods: Coded sera from 50 patients with newly diagnosed T1D and 100 healthy controls were analyzed in laboratories from 19 countries by 53 GADA assays, 52 IA-2A assays, 31 IAA assays and 19 ZnT8A assays. Six control sera that were found positive for multiple AAb or with very high titre GADA in >90% of laboratories were excluded from this analysis. Sera were categorized according to the number of laboratories calling them positive using local assay thresholds, and further stratified between patients and controls by the number of positive AAb. Category 1 (C1) included sera that were found AAb positive by at least 90% of assays. Category 2 (C2) included C1-sera plus additional sera that were found AAb positive by at least 50% of assays. Category 3 (C3) included C2-sera plus sera that were found AAb positive by at least 25% of assays.
Results: Of 50 patient sera, 41(82%) were included in C1, 45 (90%) in C2 and 46 (92%) in C3. None of the 94 control sera were included in C1 (0%), while 7 (7%) and 13 (14%) control sera were included in C2 and C3 respectively. The number of multiple AAb positive patient sera increased from 24 (59%) in C1, to 34 (76%) in C2, and 41 (89%) in C3 (p=0.001). One control serum in C3 was positive for multiple AAb. For all AAb specificities, C1-sera had significantly higher antibody titres than C2-sera (p<0.0001). Among the 46 AAb positive patient sera in C3, 18 (39%) had all four AAb, and another 15 (33%) had three positive AAb, most frequently as the combination of GADA plus IA-2A plus ZnT8A. Among single AAb positive sera, GADA were most frequently detected in both, patients (n=4) and controls (n=6).
Conclusion: We conclude that laboratories with sensitive assays for GADA, IA-2A, IAA, and ZnT8A could detect AAb in almost all sera from newly diagnosed T1D patients in the DASP 2009 workshop, and multiple AAb in up to 90% of AAb positive patient sera. AAb assays may infrequently detect positive signals against single but usually not multiple antigens in sera from controls. Discrepancies in autoantibody measurement were found to occur most commonly for low titre GADA samples and identify a subset worthy of further study.

Identification of autoantibody to Zinc Transporter 8 in Japanese diabetic patients

T. Nakagawa[1], A. Kasuga[2], T. Moriki[3], S. Oguchi[4], H. Hirose[3], I. Saito[3], M. Murata[1], T. Maruyama[5];
[1]Laboratory Medicine, Keio University School of Medicine, Tokyo, [2]Internal Medicine, Tokyo Electric Power Company's Hospital, Tokyo, [3]Health Center, Keio University, Tokyo, [4]Laboratory Medicine, Keio University Hospital, Tokyo, [5]Internal Medicine, Saitama Social Insurance Hospital, Japan.

Background and aims: Zinc transporter 8 (ZnT8) is expressed specifically on the membrane of insulin secretary granules in pancreatic β-cells. Recently, autoantibody to ZnT8 (ZnT8Ab) was reported to be implicated in type 1 diabetes especially in Caucasian. This study aimed to evaluate the clinical significance of ZnT8Ab in Japanese patients with diabetes.
Materials and methods: Sera from 1316 diabetic patients (258 from type 1 diabetes (T1D), 848 from type 2 diabetes (T2D), 210 from latent autoimmune diabetes in adults (LADA)) were collected in Saitama Social Insurance Hospital, and control sera were collected from 177 healthy subjects without any histories of diabetes or autoimmune diseases. ZnT8Ab titer was measured by radioimmunoprecipitation assay using a recombinant ZnT8 C-terminal peptide (aa268-369, Arg325; CR) or a chimeric construct of CR and CW (Trp325) (CR-CW) as antigens (kindly provided by Prof. Hutton, Colorado Univ.).
Results: Sera from healthy subjects were 1.1% positive to CR and 1.7% to CR-CW. The positive rate of ZnT8Ab was 2%, 19% and 38% in T2D, LADA and T1D, respectively. In case of T1D, the positive rate decreased markedly after 2 years from the onset; therefore, we selected and analyzed samples within one year from the onset. In this instance, the positive rate of T1D was 51% (n=94). Moreover, the positive rate was higher in age group from 13 to 19 years old (82%) than that over 20 years old (44%) (p = 0.004). We then examined the association between ZnT8Ab and other autoantibodies (GADAb, IA-2Ab) in T1D. Among sera positive to ZnT8Ab, GAD antibody (GADAb) and IA-2 antibody (IA-2Ab) was detected in 88% and 68%, respectively. Alternatively, sera negative to ZnT8Ab exhibited 67% and 36% positive to GADAb and IA-2Ab, respectively. In T1D, the prevalence of GADAb as a single autoantibody was 77%, and double positive rate with IA-2Ab was 80%. Further addition of ZnT8Ab increased the rate up to 85%. In clinical respects, serum C-peptide demonstrated a significant difference between ZnT8 positive patients and negative patients (0.75±0.57 vs. 0.96±0.66; p=0.024). And body mass index of ZnT8Ab positive patients was lower than that of negative patients (19±2.1 vs. 21±3.4; p=0.005).
Conclusion: In Japanese patients with diabetes, ZnT8Ab was positive in 51% of T1D and 2% of T2D. In T1D, patients in the age from 13 to 19 demonstrated higher positive rate than elder groups. ZnT8Ab seemed to be associated with other autoantibodies, especially such as IA-2Ab, suggesting its similar feature. Combination of ZnT8Ab in addition to GADAb and IA-2Ab increased the positive rate of autoantibodies in T1D by 5%. We supposed that ZnT8Ab might become a useful marker in Japanese diabetic patients.

431

The catalytic cysteine of islet antigen 2 is crucial to autoantibody binding in type 1 diabetes

K.T. Elvers[1], J.W. Broadhurst[1], P.R. Easton[2], V. Lampasona[3], P.J. Bingley[1], A.J.K. Williams[1];
[1]Clinical Science at North Bristol, University of Bristol, [2]Cellular and Molecular Medicine, University of Bristol, United Kingdom, [3]Center of Genomics, Bioinformatics and Biostatistics, Milano, Italy.

Background and aims: Autoantibodies to islet antigen 2 (IA-2A) are important for characterising the prodrome of type 1 diabetes (T1D) and underpin current methods of disease prediction. IA-2A show selective binding to dominant epitopes in the juxtamemebrane (JM) and protein tyrosine phosphatase (PTP) regions of IA-2. We have shown that azide and high concentrations of Tween-20 cause large reductions in binding to PTP epitopes of IA-2, possibly by modification of cysteine residues. This could disrupt disulphide bonds or modify the catalytic cysteine of the PTP active site. Our aim was to identify which cysteine residues are critical to autoantibody binding in patients with T1D.
Materials and methods: Candidate cysteine residues within a major epitope region (position 846) and the catalytic cysteine (position 909) of IA-2ic (606-979) were substituted with serine by site-directed mutagenesis. The effects of these changes on autoantibody binding were investigated by radiobinding assay using in vitro transcribed and translated 35-S labelled antigens (20,000cpm) with; (1) A panel of 22 well-characterised samples which included 19 IA-2A positive sera from 15 patients with T1D, 3 T1D relatives and 1 T1D standard pool, as well as IA-2 negative sera from 3 healthy controls (2) sera from 35 IA-2A positive patients (19 male) with newly diagnosed T1D (median age 11, range 2 to 19 years).
Results: (1) Mutation of the catalytic cysteine at position 909 caused a large reduction in IA-2A binding by the 19 well-characterised IA-2A positive sera (Figure); median 73%, range 7 to 90%, (p<0.001, Wilcoxon signed rank test), affecting sera positive for antibodies to both PTP and JM regions. In contrast, cysteine substitution at position 846 had no effect; median 3%, range -31 to 12% (p=0.167). (2) In IA-2A positive patients with T1D, mutation of cysteine 909 caused a median reduction in binding of 60%, range 21 to 79%,

(p<0.001). Mutation of cysteine at 846 again had no significant effect; median 3%, range -4 to 16% (p=0.091).
Conclusion: Mutation of the catalytic cysteine causes profound reduction in IA-2A binding by sera from patients with T1D and identifies a novel site that is critical to epitope integrity in the cytoplasmic region of IA-2. These findings indicate that the catalytic cysteine is a crucial residue in determining the conformation of IA-2.

Characterisation of IA-2 antibody epitopes by proteolysis of antibody-antigen complexes and mass spectrometry
K.A. McLaughlin[1], C.C. Richardson[1], K.A. Homer[2], M.R. Christie[1];
[1]Diabetes Research Group, [2]Department of Microbiology, Dental Institute, King's College London, United Kingdom.

Background and aims: Destruction of pancreatic beta cells in Type 1 diabetes is T-cell-mediated but circulating autoantibodies are also strongly associated with disease progression. Autoantibody-secreting B-cells participate in diabetes pathogenesis by facilitating antigen processing and presentation and are potential targets for diabetes therapy. Knowledge of autoantibody epitopes will aid the development of antigen-specific, B-cell targeted immune intervention. We have two monoclonal autoantibodies from diabetic patients that recognise dominant epitopes on IA-2, a major target of autoimmunity in the disease. Limited information on these epitopes has been obtained by amino acid substitution experiments. The aim of this study was to further define the antibody binding region by mass spectrometric identification of peptides remaining bound to antibody after proteolysis of antibody-antigen complexes.
Materials and methods: Recombinant protein representing the tyrosine phosphatase (PTP) domain of IA-2, either free or complexed with the Sepharose-bound monoclonal antibodies, were digested with chymotrypsin and antibody-bound peptides eluted at pH 11.7. Peptides were analysed by matrix assisted laser desorption/ionisation time of flight (MALDI-TOF) mass spectrometry and identified by mass comparison against a database of IA-2 chymotryptic products. Peptide identity was confirmed by liquid chromatography-tandem mass spectrometry. Acceptance criteria included a mass tolerance of less than 1.5 Da and X-correlation score of greater than 2 for doubly charged ions and greater than 2.5 for triply charged ions.
Results: Mass spectrometry of chymotryptic digestion products of free IA-2 PTP domain identified peptides with broad coverage (78%) of the molecule, whereas peptides eluted from the two monoclonal antibodies were restricted to four regions spanning positions 765-795, 813-832, 833-854 and 855-873. The latter 3 regions are adjacent on the surface of a model of the IA-2 PTP domain and encompass residues previously shown to be important in antibody binding using site directed mutagenesis. The 765-795 region is largely buried within the protein and lies directly beneath the regions previously mentioned. Six cleavage sites (at positions 794, 823, 839, 850, 856 and 872) detected with free IA-2 were never cleaved in peptides eluted from the antibodies, suggesting that antibody protects these sites from protease digestion.
Conclusion: Using antibody footprinting followed by mass spectrometry, we have mapped regions on IA-2 that represent major epitopes for diabetes-associated autoantibodies in Type 1 diabetes, confirming and extending previous studies using site-directed mutagenesis. Peptides remaining antibody-bound after proteolytic digestion closely overlap with areas of known T-cell reactivity in Type 1 diabetes, supporting the concept that B-cells influence the T-cell response through modulation of antigen processing.

Formation of insoluble immune complexes impairs detection of type 1 diabetes-associated autoantibodies in radioligand binding assays
C.C. Richardson, K.A. McLaughlin, M.R. Christie;
Diabetes Research Group, King's College London, United Kingdom.

Background and aims: Detection of autoantibodies associated with Type 1 diabetes is commonly achieved using radioligand binding assays. In these assays, complexes of serum autoantibodies with radiolabelled autoantigens are captured on protein A-Sepharose prior to quantification by scintillation counting. We have observed that a proportion of Type 1 diabetic patients show up to 5-fold higher recoveries of immunoprecipitated IA-2 or glutamic acid decarboxylase when serum antibodies are pre-bound to protein A Sepharose prior to incubation with antigen (solid phase assay) than when immune complexes are formed in solution and subsequently captured on protein A Sepharose (liquid phase assay). These observations suggested either the presence of a serum factor inhibiting autoantibody-antigen interactions, or poor binding to protein A Sepharose of immune complexes with autoantibodies of some diabetic patients. The aim of this study was to investigate the cause of these differences using IA-2 as the target antigen.
Materials and methods: Sera were selected from Type 1 diabetic patients showing higher antibody reactivity to IA-2 in the solid phase compared to liquid phase assay. IgG fractions were isolated from sera by protein A-Sepharose affinity chromatography and IA-2-specific autoantibodies affinity purified on IA-2-conjugated Sepharose and eluted at pH 11.7. Fab fragments of IgG were generated by papain cleavage. Antibody binding to radiolabelled IA-2 was analysed in two assay formats: i) where antibodies were pre-bound to protein A Sepharose and washed before addition of in vitro transcribed and translated IA-2 (40,000 cpm per reaction) for 4 h or ii) where antibodies were incubated for 4h in liquid phase with the radiolabelled IA-2 before protein A Sepharose addition. Protein A Sepharose-bound complexes were washed by centrifugation (5,000 cpm for 30 secs on microfuge) before scintillation counting. Insoluble immune complexes were isolated by centrifugation at 13,000 rpm for 20 mins and washed with 5% polyethylene glycol. All incubations were performed at 4C.
Results: Increased IA-2 antibody binding in solid phase assay was observed with both serum and protein A sepharose-purified antibodies from diabetic patients, indicating that any factor that may inhibit antibody binding was present in IgG fraction. Inhibitory effects of anti-idiotypic antibodies were shown to be unlikely because Fab fragments of IA-2 antibody-depleted IgG failed to block binding of affinity-purified antibodies to IA-2 in liquid phase assays. However, we were able to demonstrate the presence of radiolabelled IA-2 within insoluble immune complexes isolated from supernatants from the liquid phase assays. These insoluble immune complexes failed to bind protein A Sepharose. Radiolabelled IA-2 was not detected in insoluble immune complexes isolated from solid phase assays.
Conclusion: This study demonstrates that a proportion of Type 1 diabetic patients possess circulating IA-2 autoantibodies that form insoluble immune complexes with antigen with poor binding to protein A. Assays dependent on protein A capture of immune complexes may underestimate autoantibody levels in those patients and these observations need to be considered when designing new protocols for autoantibody detection. The ability to form insoluble immune complexes in vivo may have implications for tissue damage and the regulation of autoimmune responses in the diabetic patient.

Seroconversion to persistent antibody-positivity occurs frequently after age 10 and is best predicted by GAD antibodies
I. Vermeulen, I. Weets, O. Costa, M. Asanghanwa, K. Decochez, J. Ruige, K. Casteels, D. Pipeleers, F. Gorus, Belgian Diabetes Registry;
Belgian Diabetes Registry, Brussels, Belgium.

Background and aims: The appearance of autoantibodies (Ab^+) before clinical diabetes onset has mainly been studied in children. However, most patients develop type 1 diabetes in adulthood. We studied seroconversion to Ab^+ in first-degree relatives aged 0-39 years to determine 1) age distribution

at seroconversion; 2) predictors of Ab-persistence and prediabetes; 3) order of appearance of different Ab-types.
Materials and methods: Seroconverters (n=221) were identified by measuring Abs against insulin (IAA), islet cell cytoplasm (ICA), GAD (GADA), IA-2 (IA-2A) and zinc transporter 8 (ZnT8A-CRCW) during follow-up of 6125 first-degree relatives.
Results: One hundred and five (48%) relatives seroconverted to persistent Ab^+. Most seroconversions (63%) occurred after age 10. Persistently Ab^+ relatives were more frequently $GADA^+$ (61% vs 23%) and multiple Ab^+ (26% vs 2%) (resp. $p<0.001$ and $p<0.008$ by logistic regression) at seroconversion than transiently Ab^+ relatives. The prevalence of IA-2A and ZnT8A was initially the lowest (resp. 12% and 7%) but increased most thereafter (resp. +100% and +214% vs +24% for IAA and +11% for GADA). Progression to diabetes occurred almost exclusively (20/22) in persistently Ab^+ relatives ($p<0.001$ by logrank vs transiently Ab^+) and preferentially in case of seroconversion under age 10 ($p<0.021$). Still, 9 (41%) prediabetics, had seroconverted after age 10.
Conclusion: 1) Seroconversion after age 10 is not a rare event; 2) GADA is the best predictor of Ab-persistence which is in turn associated with progression to diabetes; 3) in case of Ab-persistence, IA-2A and ZnT8A preferentially mark later disease stages, compatible with their known association with rapid progression to diabetes.

Frequency of development of type 1 diabetes mellitus and immunity indices in prediabetic children of Ukraine who are positive to autoantibodies to Langerhans islet antigens
V.V. Popova, K.P. Zak, B.M. Mankovsky, M.D. Tronko;
Dept. of Preventive Diabetology, Institute of Endocrinology and Metabolism, Kiev, Ukraine.

Background and aims: The discovery of human diabetes-associated autoantibodies (DAAb) contributed to an early prediction of development of type 1 diabetes mellitus (T1DM) and to investigations of the immunological mechanisms of its progression to a latent stage. In 1998, for the first time in Ukraine a Programme "Immunity at preclinical stage of T1DM progression" has been developed by the Institute, whose purpose was a prospective study of the frequency of T1DM development and dynamics of changes in several immunity indices in prediabetic period among children of a number of regions of Ukraine, who have a family history of diabetes and are positive or negative to the presence of DAAb.
Materials and methods: 450 children aged 13.62±2.34 years were followed up. Out of 366 practically healthy normoglycemic children with first degree relatives having T1DM, 94 were positive (group A) and 272 (group B) negative to DAAb (GADA and IA-2A). A control group C comprised 84 normoglycemic children without a family history of diabetes and being DAAb-negative. The measurements of IAA, GADA, and IA-2A titers were carried out by radioimmunoassay, the immunophenotype of lymphocytes (CD3+, CD4+, CD8+, CD20+, and CD56+ cells) by FACS-analysis, the content of cytokines (IL-1, IL-4, IL-6, IL-8, IL-10, IL-16, TNFα, and IFN-γ) by ELISA.
Results: T1DM has appeared in different periods of follow-up (from 6 months to 9 years: 30.9±3.2 months) in 48.9% of children from group A and in one child (0.8%) from group B. Among relatives of group A subjects, in 55.3% of children the sibs, in 36.1% the father, and in 9.6% the mother, had diabetes. Group A, unlike groups B and C, was characterized by a lower absolute number of content of CD3+ ($0.79\pm0.05 \times 10^9$/L), CD4+ ($0.52\pm0.03 \times 10^9$/L), and CD56+ ($0.18\pm0.02 \times 10^9$/L) cells in peripheral blood compared to group C ($1.39\pm0.09 \times 10^9$/L; $p<0.01$; $0.98\pm0.04 \times 10^9$/L; $p<0.001$; $0.29\pm0.02 \times 10^9$/L; $p<0.01$, respectively), and group B ($1.02\pm0.06 \times 10^9$/L; $p<0.05$; $0.67\pm0.04 \times 10^9$/L; $0.24\pm0.03 \times 10^9$/L; $p<0.01$, respectively), and by a higher concentration of circulating IL-1α, IL-6, IL-8, IL-16, TNFα and a decreased IL-4, with a higher degree of changes of these indices at preclinical stage in a number of patients than after disease manifestation. In children from group A, whose father had T1DM and in which a higher simultaneous increase in GADA and IA-2A titers correlated with the most pronounced decrease in the content of IL-4 and CD3+ cells ($0.59\pm0.05 \times 10^9$/L; $p<0.01$) and of CD4+ cells ($0.38\pm0.03 \times 10^9$/L; $p<0.01$), CD56+ cells ($0.15\pm0.03 \times 10^9$/L; $p<0.01$), and with elevated levels of IL-16, IL-8, TNFα and IFN-γ, a faster progression of T1DM (16.32±4.45 months vs 30.9±3.2 months, $p<0.01$) was reported, along with a more aggressive character of disease course.
Conclusion: The frequency of development of T1DM in DAAb+ normoglycemic children of Ukraine is near the upper limits of this index for other countries. The velocity of T1DM progression and aggressiveness of disease course depend not only on the presence of a higher DAAb titer and the degree of changes in T- and NK-immunity indices, but on the presence of a history of diabetes in one of the parents as well.

436

Role of diabetic family history in the prediabetic autoimmune process in children recruited from the general population based on HLA-associated disease risk
H.T.A. Siljander[1,2], R.-T. Salonsaari[2], A. Hekkala[3], S. Simell[4], R. Veijola[3], J. Ilonen[5,6], O. Simell[4], M. Knip[1,2];
[1]Research Laboratory, Hospital for Children and Adolescence, Helsinki, [2]Department of Pediatrics, Tampere University Hospital, [3]Department of Pediatrics, University of Oulu, [4]Department of Pediatrics, University of Turku, [5]Department of Clinical Microbiology, University of Kuopio, [6]Immunogenetics Laboratory, University of Turku, Finland.

Background and aims: To assess differences in the in the appearance and progression of beta-cell autoimmunity between children with and without first-degree relatives (FDRs) affected by type 1 diabetes (T1D) in a study cohort recruited from the general population based on HLA-conferred disease risk.
Materials and methods: 7410 children with HLA-conferred disease risk were recruited at birth from the general population and observed for 9.2 years (median) for beta-cell autoimmunity and T1D. At birth 177 (2.4%) of the children had affected FDRs. ICA were used for autoantibody screening. After ICA-positivity or T1D was confirmed, all samples available from that individual were analyzed for ICA, IAA, GADA, and IA-2A. Children with advanced autoimmunity (persistent positivity for ≥2 diabetes-associated autoantibodies, DAAs) were eligible for an intervention trial with nasally administrated insulin/placebo that proved to have no effect on progression to T1D.
Results: Children with affected FDRs seroconverted to autoantibody positivity and developed persistent multipositivity more frequently, and seroconverted at a younger age than children without FDRs with T1D (Table 1). They had also higher autoantibody levels throughout the follow-up. However, in children with advanced multipositivity autoantibody levels were similar regardless of family history. In children with affected FDRs, paternal T1D was associated with higher risk of seroconversion (paternal vs. maternal/sib: OR 2.0 [$CI_{95\%}$ 1.0-3.9], P=0.04), persistent multipositivity (OR 2.2 [$CI_{95\%}$ 1.0-5.0], P=0.048), and T1D (OR 4.5 [$CI_{95\%}$ 1.7-11.7], P=0.002) than maternal T1D or T1D in siblings. For comparison, OR for T1D in children with paternal T1D vs. children without affected FDRs was 13.4 ($CI_{95\%}$ 7.8-23.1).
Conclusion: The most conspicuous effect of familial T1D is seen in the initiation of the preclinical disease process. Children with paternal T1D are at the highest risk of developing beta-cell autoimmunity and T1D. After the diabetic autoimmune process is established, the FDR status plays a minor role in terms of disease progression.

Table 1. Beta-cell autoimmunity in children with HLA-conferred disease risk in relation to family history of type 1 diabetes (T1D).

	Family history of T1D	
	Positive	Negative
	N (%)	
ICA-based seroconversion	49 (27.7)	1124 (15.5)*
Seroconversion sample multipositive	16 (32.7)	145 (12.9)*
Positivity for ≥2 DAAs	38 (21.5)	353 (4.9)*
Persistent autoantibody positivity	40 (22.6)	632 (8.7)*
Persistently positive for ≥2 DAAs	31 (17.5)	252 (3.5)*
Progression to T1D	24 (13.6)	156 (2.2)*
	Years, median (range)	
Age at seroconversion	3.0 (0.3–10.5)	4.0 (0.2–13.7)†
Delay from seroconversion to diagnosis of T1D	2.8 (0.3–8.6)	2.8 (0.0–10.9)
Age at diagnosis (all children with T1D)	4.8 (0.9–11.4)	5.1 (1.0–12.5)

*P≤0.001, †P=0.02.

Effect of family history of type 1 diabetes on the phenotype of type 2 diabetes

V.M. Lundgren[1,2], M.K. Andersen[3,4], B. Isomaa[5], L. Groop[1,6], T. Tuomi[1], Botnia Study Group;
[1]Department of Medicine, Helsinki University Central Hospital, [2]Folkhälsan Research Centre, Helsinki, [3]Research Program of Molecular Medicine, Helsinki, [4]Research Program of Molecular Medicine, University of Helsinki, [5]Folhälsan Östanlid and Malmska Municipal Health Care, Jacobstad, Finland, [6]Department of Clinical Sciences-Diabetes & Endocrinology, Malmö, Sweden.

Background and aims: Type 2 diabetes (T2D) is a heterogeneous disease and 10- 20 % of patients develop marked insulin deficiency. Some have GAD antibodies (LADA, latent autoimmune diabetes in adults) and share susceptibility genotypes with type 1 diabetes. In Finland, Type 1 and Type 2 diabetes cluster in same families. We evaluated the impact of family history of diabetes and susceptibility genotypes on the phenotype of type 2 diabetic patients.
Materials and methods: We recruited 197 T2D patients with family history of T1D and 139 matched (age, age of onset, BMI, sex) T2D controls with family history of T2D only. Phenotypical data included an oral glucose tolerance test (OGTT) and i.v. glucagon test followed by i.v. insulin tolerance test (GITT) and GAD antibodies (GADA). Patients were genotyped for T1D (*HLA-DQA1-DQB1, PTPN22, INS*) and T2D (*TCF7L2,FTO, PPARG, KCNQ1, SLC30A8*) susceptibility genes. Patients were stratified according to T1D family history and GADA positivity.
Results: There were altogether 58 GADA+ T2D patients; 43 with T1D family history ($LADA_{MIX}$; 30 had 1st degree relatives with T1D) and 17 with family history for T2D only ($LADA_{T2}$), p=0.024. The $LADA_{MIX}$ patients had higher HbA1c and glucose values during OGTT than both $LADA_{T2}$ and GADA- T2D patients with mixed family history ($T2D_{MIX}$) (table 1). They were less obese and they had lower measures of insulin secretion (fasting and glucagon-stimulated C-peptide, corrected insulin response during 30 min of OGTT, CIR) even when adjusted for the degree of insulin resistance (Disposition index). 37.2% of the $LADA_{MIX}$ patients had markedly decreased stimulated C-peptide (< 0.7 nmol/l) compared to 10.4% of $T2D_{MIX}$ and 4.9% of $T2D_{T2}$ patients(p<0.001). Surprisingly the $LADA_{MIX}$ patients also seemed to be more insulin resistant (higher HOMA and lower K_{ITT} during the insulin tolerance test), but this could be due to worse diabetes control. $LADA_{MIX}$ patients had significantly more often *HLA-DQ* T1D risk genotypes 19/43 (44.2%) compared with $T2D_{MIX}$ 39/154 (25.3%; p=0.05) and $T2D_{T2}$ 17/121 (14.0%; p=0.0003).
Conclusion: TID family history together with GADA positivity is associated with insulin deficiency in type 2 diabetic patients.

Table: Data are means ± SD or median (IQR). In statistical analyses (Ancova) the data were adjusted for sex. *p<0.05, **p<0.001 $LADA_{MIX}$ vs $T2D_{MIX}$, † p<0.05, †† p<0.001 $LADA_{MIX}$ vs $LADA_{T2}$

PS 22 T regulatory cells and Th17 immunity in type 1 diabetes

438

IL-17 immunity in human type 1 diabetes

J. Honkanen[1], J.K. Nieminen[1], R. Gao[2], K. Luopajärvi[1], H.M. Salo[1], J. Ilonen[3,4], M. Knip[5,6], T. Otonkoski[2], O. Vaarala[1];
[1]Department of Vaccination and Immune Protection, National Institute for Health and Welfare, Helsinki, [2]Biomedicum Stem Cell Center, University of Helsinki, [3]Immunogenetics Laboratory, University of Turku, [4]Department of Clinical Microbiology, University of Eastern Finland, Kuopio, [5]Hospital for Children and Adolescents, University of Helsinki, [6]Department of Pediatrics, Tampere University Hospital, Finland.

Background and aims: T1D is considered as an autoimmune disease caused by T-cell mediated destruction of the insulin-producing pancreatic beta-cells. Th17 immunity has been demonstrated in the development of autoimmune diabetes in animal models. IL-17 neutralization prevented development of diabetes in NOD mice. Moreover, islet-cell antigen specific Th17 cells converted into IFN-γ secreting Th1-like cells and caused diabetes in mice recipients. Our aim was to address the role of Th17 cells in human T1D.
Materials and methods: We studied 15 children with T1D and 12 non-diabetic children for the comparison of IL-17 immunity in PBMCs stimulated with plate-bound anti-CD3 and soluble anti-CD28 for 40h. Culture supernatants were collected for cytokine analysis and stimulated cells were collected for gene expression analysis of IL-17, ROR-C2, IL-22, IFN-γ, T-bet and FOXP3 with qRT-PCR. Th17 immunity associated genes in freshly purified CD4+ memory T-cells were also compared between nine T1D patients and eight healthy children. CCR6, TCR-αβ, TCR-γδ and intracellular IFN-γ expression of IL-17 producing cells were analysed by flow cytometry. The apoptotic and inflammatory effects of IL-17 alone or in combination with IL-1β and IFN-γ on human islets from five different donors were studied in vitro with qRT-PCR. The proportion of apoptotic islets cells were determined by nuclear double staining with Hoechst 33342 and propidium iodide.
Results: We observed increased IL-17 secretion (p=0.018, median 173 pg/ml vs. 0 pg/ml), and mRNA expression (p=0.012, median 42 RU vs. 3 RU) in activated PBMC from patients with T1D. Also ROR-C2 (p=0.02, median 70 RU vs 19 RU), IL-22 (p=0.005, median 3.6 RU vs. 0.9 RU), and FOXP3 (p=0.03, median 40 RU vs. 25 RU) showed increased expression in diabetic children. No difference was observed in the expression level of IFN-γ or T-bet. IL-17A and IL-22 mRNA was expressed in the population of CD4+ memory T-cells from children with T1D, whereas minimal or undetectable expression levels were seen in healthy children (6/8 vs 0/8; p=0.007 for IL-17 and 5/8 vs 0/7; p= 0.026 for IL-22). Higher expression level of FOXP3 in CD4+ memory T cells were seen in children with T1D than in healthy children (5/9 vs 0/8; p=0.009). IL-17 positive T cells of T1D patients appeared to be CD4+ cells expressing TCR-αβ and CCR6, and a subpopulation showed co-production of IFN-γ. In combination with IL-1β and IFN-γ, IL-17 enhanced up-regulation of iNOS, COX-2, SOD-2 and down-regulation of anti-apoptotic gene BCL-2.
Conclusion: The activation of IL-17/IL-22 immunity is a major immune alteration in children with T1D. Simultaneous up-regulation of IL-17 with FOXP3 or IFN-γ suggests aberrant immune regulation in T1D. IL-17 was shown to be detrimental for human islet cells, and IL-17 together with IL-1β and IFN-γ enhanced the stress response of islet cells. We conclude that the activation of IL-17 producing cells may be involved in the pathogenesis of human T1D.

The role of regulatory $CD4^+CD25^+$ T lymphocytes and FoxP3 expression in evolution and progression of type 1 diabetes

T.V. Nikonova[1], E.V. Pekareva[1], V.A. Gorelysheva[1], P.V. Apanovich[2], S.A. Prokofyev[1], I.I. Dedov[1];
[1]Endocrinology Research Center, [2]Medical Genetics Research Center, Moscow, Russian Federation.

Background and aims: $CD4^+25^+$ T-lymphocytes (Treg) play a crucial role in the regulation of immune response. Lack of amount and/or activity may cause loss of self-tolerance to beta-cell autoantigens and the development of autoimmune process. The aim was to evaluate changes in terms of number or function of Tregs in high-risk diabetes subjects who are positive for diabetes-

specific autoantibodies and have a genetic susceptibility and type 1 diabetes mellitus (T1DM) patients at different stages of the disease.
Materials and methods: We examined 85 patients with T1DM at different stages of the disease: 36 patients with recent-onset T1DM, 12 - with the duration of diabetes from 1 to 5 years, 11 - from 5 to 10 years, 26 - over 10 years. 14 subjects at high-risk diabetes and 8 healthy subjects (control group) also included in the study. The HLA-DR and DQ alleles were detected by using PCR method. $CD3^+$, $CD4^+$, $CD8^+$, $CD38^+$, HLA-DR^+, $CD25^+$, $CD4^+25^+$ cells were analyzed by flow cytometry. FoxP3 expression was determined by Real Time PCR. All subjects were tested for islet cell antibodies, autoantibodies to glutamic acid decarboxylase, insulin and tyrosine phosphatase, C-peptide, HbA_{1c}.
Results: An increasing tendency of CD 25^+ and $CD4^+25^+$ T-lymphocytes and decreasing tendency of FoxP3 expression between control and high-risk subjects was observed ($p<0.1$). Significant differences were found in content of activation molecules CD38 and HLA-DR ($p<0.05$) in those groups, indicating the tension of the immune system. There was no significant difference in the percentage of Tregs in patients with recent-onset T1DM (0.8% [0.6; 0.8]) and control subjects (0.8% [0.3; 2.1]). However FoxP3 expression was significantly lower in patients with recent-onset T1DM than in the control group (0.39 [0.18; 0.71] vs. 1.11 [0.66; 2.26], $Z = 5.26$, $p<0.001$). Reduced FoxP3 expression was observed at any stage of the disease compared with control subjects. FoxP3 expression was 0.37 [0.18; 0.89] ($Z = 2.62$, $p<0.01$) in patients with duration of diabetes from 1 to 5 years; 0.14 [0.11; 0.31] ($Z = 3.33$, $p<0.01$) in patients with duration of diabetes from 6 to 10 years and 0.47 [0.17; 0.86] ($Z = 3.15$, $p<0.01$) over 10 years of the disease.
Conclusion: A rising tendency of Tregs in high-risk subjects may appoint for suppression of autoimmune process. Despite the fact that there was no significant difference in the content of Tregs in patients with T1DM compared with control subjects, their functional activity - FoxP3 expression was significantly lower at any stage of the disease, which may indicate the reduced ability to suppress T cell proliferation.

440

The deficiencies of T regulatory lymphocytes (Tregs) in cell amount, expression and coordination of suppresion-related proteins at type 1 diabetes onset are only partially remedied in long term patients

S.A. Paschou[1], G. Vartholomatos[2], A. Petsiou[2], N. Kolaitis[3], E. Giotaki[4], A. Tsatsoulis[1], G.K. Papadopoulos[5];
[1]Department of Endocrinology, University of Ioannina Regional Hospital, [2]Molecular Biology Unit, Haematology Laboratory, University of Ioannina Regional Hospital, [3]Haematology Laboratory, University of Ioannina Regional Hospital, [4]Department of Nursing, Epirus Institute of Technology, Ioannina, [5]Laboratory of Biochemistry and Biophysics, Epirus Institute of Technology, Arta, Greece.

Background and aims: T regulatory lymphocytes (Tregs) play an important role in tolerance and autoimmunity. Tregs, defined as $CD4^+CD25^{high}$ T lymphocytes, and are thought to regulate the immune response in mammals. We previously showed a deficiency of Tregs in cell amount, expression and coordination of suppression-related proteins in newly-diagnosed type 1 diabetics (t1d) compared to controls. The aim of our study was to investigate the various features of Tregs in long standing t1d patients and to identify differences between them and newly diagnosed t1d patients.
Materials and methods: Peripheral blood from 13 newly-diagnosed patients (9M/4F, ages 12.5 ± 9.4 years), 26 long-standing patients (12 M/14 F, ages 26.7 ± 9.2 years) with mean disease duration of 11.6 ± 7.4 years (range 2-25 years) and 32 healthy controls with no first or second degree relatives suffering from any autoimmune disease (13 M/19 F, ages 25.3 ± 11 years) was analysed by flow cytometry for various phenotypic markers of Tregs. We included as such, molecules that had been linked to Treg function (FoxP3, CD28, CD45RO, CD127, CD152, TGFβ and TGFβRII), gene products or their receptors linked to heredity in type 1 diabetes (HLA-DR/DQ, CD25, InsR, CD152) and proteins linked to apoptosis (CD95) and cell proliferation (CD27). The statistical analysis was performed using SPSS for Windows, Version 16.0.
Results: Newly-diagnosed t1d patients have a significantly lower percent of Tregs (as percent of total $CD4^+$ T cells) compared to controls: 1.259 ± 0.264 % vs 3.047 ± 0.264 % respectively, $p < 0.001$. Long standing t1d patients have an intermediate value of Tregs, 1.748 ± 0.308 %, that is significantly different from that of both controls ($p < 0.001$) and long standing patients ($p < 0.001$), suggesting a "rebound phenomenon". Tregs of controls exhibit highly coordinated control of the frequency of expression of markers such as IL-2Rβ, CTLA-4, InsR, TGFβ, TGFβRII, HLA-DQ, and HLA-DR, several of these being products of t1d susceptibility genes. In newly-diagnosed patients there is a near total absence of coordinated expression of these markers, and a decreased level of expression of TGFβ and TGFβRII. In long-term patients there is a deficiency of expression of TGFβ, while there is an increase in the level of TGFβRII and the frequency of Tregs expressing HLA-DR and CD95; here the coordinated expression involves mostly CD45RO, CD95, IL-2Rβ, and HLA-DQ.
Conclusion: Our data are consistent with a pathogenesis mechanism that actively disrupts the amount, functioning and coordinated expression of effector molecules in Tregs at disease onset, while at long term these deficiencies are only partially remedied.

The effect of Vitamin D supplementation on peripheral regulatory T cells in healthy humans, a randomised controlled trial

B. Prietl[1], G. Bock[1], J.K. Mader[1], E. Höller[1], M. Wolf[1], S. Pilz[1], W.B. Graninger[2], B.M. Obermayer-Pietsch[1], T.R. Pieber[1];
[1]Department of Endocrinology and Nuclear Medicine, [2]Department of Clinical Rheumatology and Immunology, Medical University of Graz, Austria.

Background and aims: Regulatory T cells (Tregs) play a central role in the maintenance of self tolerance and immune homeostasis. Thus an imbalance between different types of T cells, such as effector T cells and Tregs, has been reported to play a major role in the pathogenesis in autoimmune diseases like type 1 diabetes. Growing bodies of evidence from animal and in vitro studies suggest a role for vitamin D in modulating the function of CD4+ T cells, including Tregs. In the present study, we aimed to elucidate, whether supplementation with vitamin D has the potential to increase the number or function of peripheral Tregs in apparently healthy human individuals. Furthermore we investigated the pleiotropic in vivo effects of Vitamin D supplementation on other important circulating cells of the human innate and adaptive immune system.
Materials and methods: A double-blinded and placebo controlled trial was performed among 35 healthy subjects (46% females, mean age: 35 ± 11 years). Subjects were randomized to oral vitamin D (140 000 IU monthly) or placebo treatment for 3 months. Peripheral blood was drawn at baseline and monthly visits and the percentage of Tregs within 20000 CD4+ T cells as well as the percentage of other circulating cells of the human innate and adaptive immune system were determined by using a multi-parametric FACS-analysis. Functional tests for FACS-sorted Tregs were assessed in a 3H-Thymidin based suppression co-culture, including stimulation of effector cells with anti CD3/CD28 beads.
Results: 25-hydroxyvitamin D levels were significant higher in the vitamin D treated group than in the placebo group (mean level at 3 months: 60.2 ± 21.1 ng/ml vs 18.8 ± 7.2 ng/ml). Accordingly, the median percentage of Tregs increased significantly from a median baseline level of 4.8% (interquartile range: 4.3-5.8%) to a level of 6.4% (5.9-7.2%) at month 3 ($p<0.001$ for general linear model with repeated measurements) in the vitamin D group whereas there was no statistically significant change in the placebo group ($p=0.956$). Between group comparison at month 3 revealed a significant difference in the median levels of %Tregs ($p=0.017$). Suppressive function of regulatory T cells remained unchanged in both groups. Furthermore, analysing the other peripheral immune cells showed no statistically significant chances in the frequency of naive CD4+ and CD8+ T cells, memory CD4+ and CD8+ T cells, CD25++CD8+ cells, NK cells, NKT cells, B cells, monocytes, granulocytes, stem cells and blood dendritic cells (myeloid and plasmacytoid DC) in both groups. C-reactive protein was within the normal range before and after the treatment and did not change significantly between the study visits. In both groups no clinically relevant adverse events have been reported.
Conclusion: High dose of vitamin D supplementation increased the frequency of peripheral Tregs significantly in healthy subjects. This finding supports previously described associations of vitamin D deficiency and autoimmune diabetes and provides a rationale for further studies to investigate the immunemodulatory effects of vitamin D in diabetic subjects.

442

Insulin treatment during pregnancy induces insulin-reactive CD4+CD25+FOXP3+ regulatory T cells in the infant

K. Luopajärvi[1], J.K. Nieminen[1], J. Ilonen[2,3], H.K. Åkerblom[4], M. Knip[4,5], O. Vaarala[1];
[1]Immune Response Unit, National Institute for Health and Welfare, Helsinki, [2]Department of Clinical Microbiology, University of Eastern Finland, Kuopio, [3]Immunogenetics Laboratory, University of Turku, [4]Hospital for Children and Adolescents, University of Helsinki, [5]Department of Pediatrics, Tampere University Hospital, Finland.

Background and aims: Reduced risk for type 1 diabetes (T1D) has been reported in the offspring of mothers with T1D when compared to children of affected fathers. To evaluate the hypothesis that exposure of the offspring to maternal diabetes and insulin therapy results in tolerization to insulin *in utero* and thereby decreases the risk for T1D, we compared the FOXP3 expressing regulatory T cells in cord blood of infants born to mothers with or without T1D.
Subjects and methods: Cord blood mononuclear cells from 20 infants with maternal T1D and from 20 infants with an unaffected mother were analysed for the expression of CD4+CD25+ cells and FOXP3 ex vivo and after 72h stimulation with human insulin by flow cytometry. The mRNA expression of FOXP3, TGF-β and IL-10 was measured by real-time RT-PCR.
Results: The percentage of CD4+CD25^{high}FOXP3+ cells in cord blood was higher in the infants of mothers with T1D than in the infants of unaffected mothers ($p = 0.023$; median values 31.5% [range 6.1-63.1%] and 16.4% [range 2.0-36.3%], respectively). The numbers of FOXP3 positive CD4+CD25^{high} cells were higher after *in vitro* stimulation of cord blood cells with human insulin than in unstimulated cord blood cells in the infants with maternal T1D ($p < 0.001$; Wilcoxon test; median values 17.2% [range 2.4-56.9%] and 28.1% [range 8.4-60.8%]). In infants of non-diabetic mothers there was no difference in FOXP3 expression in CD4+CD25^{high} T cells stimulated with insulin compared to non-stimulated CB mononuclear cells ($p = 0.21$, Wilcoxon test; median values 10.9% [range 1.0-35.3] and 15% [range 0.7-31.4%]. Furthermore, an increased intensity of FOXP3 in CD4+CD25^{high} cells was observed in response to insulin stimulation in infants of T1D mothers ($p < 0.05$). Only in infants with maternal diabetes FOXP3-, IL-10- and TGF-β specific mRNA increased in cord blood cells in response to insulin (Wilcoxon- test $p < 0.001$, $p = 0.003$, $p = 0.013$, respectively). The HLA genotype did not modulate the results.
Conclusion: We suggest that maternal insulin treatment induces expansion of insulin-specific FOXP3 expressing regulatory T cells in the fetus, likely due to tolerization to insulin through transplacental transfer of insulin bound to insulin antibody complexes.

Otelixizumab differentially modulates human regulatory and non-regulatory T cells

I. Apostolou, J. Guild, L. Vaickus, M. Rosenzweig;
Tolerx, Inc., Cambridge, USA.

Background and aims: Otelixizumab is an Fc-disabled monoclonal antibody (mAb) with specificity for CD3ε that has been shown to preserve β cell function in subjects with new onset type 1 diabetes mellitus (NOT1DM). Otelixizumab is being evaluated in placebo-controlled Phase 3 clinical studies in NOT1DM patients. The cellular and molecular mechanisms by which otelixizumab and other anti-CD3 mAbs turn off the autoimmune attack in humans are not well understood. Although otelixizumab binds to all T cells, treated subjects do not exhibit signs of chronic immunomodulation other than arrest of the pathogenesis mediated by pancreas-specific T cells. This suggests that this apparently non-antigen-specific therapy selectively signals antigen-activated T cells. Furthermore, peripheral blood Foxp3$^+$ CD4$^+$ regulatory T cells (Tregs) increase after otelixizumab administration, suggesting that it promotes Treg expansion/migration as well as function. This prompted us to investigate whether otelixizumab has a differential effect on distinct T cell subsets and whether it preferentially regulates activated T cells in an *in vitro* model of antigen reactivity.
Materials and methods: Mixed lymphocyte reactions (MLRs), using HLA-A2 mismatched donors to distinguish responders from stimulator cells, were conducted without or with otelixizumab. Proliferation and survival of CFSE-labeled responder Tregs, activated effector T cells (Teffs), and naïve T cells were examined by flow cytometry.
Results: Otelixizumab markedly inhibited the proliferation of alloantigen-specific Teffs in primary MLRs as well as secondary MLRs, where the mAb was added to primed alloantigen-specific Teffs. Inhibition of T cell proliferation was dose-dependent and peaked at the highest saturating concentration of otelixizumab. Subsaturating concentrations of mAb resulted in the proliferation of a subset of T cells with an activated but not a naïve phenotype, and the number of naïve T cells did not decrease in the presence of mAb. Addition of otelixizumab to primary MLRs was accompanied by the appearance of and an increase in the number of dividing Tregs, irrespective of the dose. Otelixizumab-induction of Treg proliferation was optimal at subsaturating concentrations. The dose-dependent inhibition of T cell proliferation was more pronounced among Teffs than Tregs, resulting in a ~5-fold decrease in the ratio of dividing Teff:Tregs at saturating concentrations of mAb as compared to controls. Furthermore, addition of otelixizumab to primary MLRs was associated with increases in non-dividing Tregs, suggesting that otelixizumab can induce Treg-commitment in activated T cells. Lastly, no mAb-induced cell death was observed.
Conclusion: These studies indicate that Tregs, activated Teffs, and naïve T cells respond differently to otelixizumab and to different concentrations of otelixizumab. Naïve T cells were minimally affected by otelixizumab. In contrast, otelixizumab induced a significant increase in Tregs that exhibited a lower susceptibility to otelixizimab-mediated inhibition of proliferation than activated Teffs. This suggests that otelixizumab's immunoregulatory effects are principally confined to activated Teffs and Tregs, and are markedly affected by dose. Further experiments comparing otelixizumab-induced signaling cascades in the various T cell subsets and the antigen specificity and potency of otelixizumab-expanded Tregs are being conducted.

Dynamic changes of CD95 and CD95L expression on lymphocytes in patient with new-onset type 1 diabetes mellitus

E.V. Pekareva, T.V. Nikonova, V.A. Gorelysheva, S.M. Stepanova, S.A. Prokofyev, O.M. Smirnova, I.I. Dedov;
Endocrinology Research Centre, Moscow, Russian Federation.

Background and aims: The CD95 molecule triggers cell apoptosis. It is expressed by activated lymphocytes and involved in switching-off the immune response. Impaired CD95 expression may play a role in type 1 diabetes mellitus (T1DM) initiation. Expression of apoptosis molecules is impaired in T1DM. Aims were: (i) To determine expression of apoptosis molecules on lymphocytes in patients with T1DM at onset of disease. (ii) To compare these parameters during the first year of the disease.
Materials and methods: 29 patients (12 women and 17 men) T1DM included. Age of onset diabetes (median) was 29 years old. Expression of surface CD95 and CD95L molecules on peripheral blood lymphocytes was measured in onset, remission period, and 12 months after diagnosis. CD95 and CD95L expression was detected by flow cytometry, using monoclonal antibodies. Samples for HbA_{1c} analysis were collected at onset and after 3, 6 and 12 months. The patients were also examined for C-peptide, HLA-typing and tested for islet cell antibodies, antibodies to glutamic acid decarboxylase, insulin autoantibodies and tyrosine phosphatase-like IA-2.
Results: 17 (59%) patients entered partial remission and 3 (10%) patients had complete remission. The susceptible genetic haplotypes, in particular DR3/DR4, were prevalent. HbA_{1c} level was 11.5% [10.8; 12.9] at onset, 6.9% [6.5; 8.1] after 6 months and 6.5% [5.3; 7.9] after 12 months. CD95 expression on lymphocytes was significantly lower at onset T1DM than at remission of the disease (p=0.02) and than after 12 months (p=0.05). The amount of CD95-positive cells was 29% [27.1; 32.5] at onset; 33.5% [31.5; 38.8] at remission phase and 33% [29.5; 39.1] after 12 months. No significant differences were found in CD 95L expression on lymphocytes between onset and after 12 months (p=0,21). Expression CD95L was similar during first year of disease. The amount of CD95L-positive cells were 1.4% [1.0; 3.0] at onset; 2.5% [1.6; 5.2] 12 months later. Autoantibodies titers decreased in the remission phase of the disease.
Conclusion: There are a lower level of CD95 expression on lymphocytes in new-onset T1DM patient and increase of it during the first year of the disease. This low CD95 expression on lymphocytes could be a contributing factor to markedly decreased suppressive potential of these cells in the initial phase of disease. We suggest that suppression of activated lymphocytes apoptosis may contribute to prolongation of autoimmune response in new-onset T1DM.

Analysis of expression of Th1 and Th2-associated chemokine receptors on CD4+ T lymphocytes: comparison between recent onset type 1 diabetics and nondiabetic first degree relatives

T. Milicic[1], N. Lalic[1], A. Jotic[1], I. Markovic[2], M. Zamaklar[1], K. Lalic[1], L. Lukic[1], N. Rajkovic[1], M. Macesic[1], J. Seferovic[1], S. Aleksic[1];
[1]Clinical Center of Serbia, Institute for Endocrinology, [2]University of Belgrade, Institute for Biochemistry, Belgrade, Serbia.

Background and aims: Previous studies have reported an important role of the chemokine receptors CXCR3 and CCR4, which are associated with Th1 and Th2 CD4+ cell subsets respectively and involved in their extravasations into inflamed pancreatic islets, in the initial phase of Type 1 diabetes (T1D). However, the changes in CXCR3+ and CCR4+ subsets of the memory $CD4^+$ CD45RO+ T cells in recent onset type 1 diabetics and their nondiabetic first-degree relatives (FDRs), have not yet been clarified. Therefore, the aim of this study was to analyze the percentage of the (a) CXCR3+ (Th1 associated) and (b) CCR4+ (Th2 associated) subsets of T memory cells, in peripheral blood in 24 recent-onset T1D patients in insulin-requiring state (IRS) at the onset (group A), 10 T1D patients in the state of clinical remission (CR) (group B), 41 nondiabetic FDRs (group C), as well as in 18 healthy, age-matched control subjects (group D).
Materials and methods: T1D was diagnosed in accordance to WHO criteria. The CR was defined as optimal metabolic control without insulin lasting >30 days. The percentages of CXCR3+ and CCR4+ T memory $CD4^+$ CD45RO+ cell subsets were analyzed in peripheral blood by using four-color immunofluorescence staining and flow cytometry.
Results: We found that there was no difference among the groups concerning the percentage of CD4+CD45RO+ T lymphocytes (A: 27.23±8.54 vs B: 24.19±6.50 vs C: 25.73±6.78 vs D:27.67±6.59 %, A vs B vs C vs D, p=NS). However, when the percentage of CXCR3+ T memory lymphocytes was analyzed, we found that in groups A and B it was significantly lower than in groups C and D (A: 40.19±11.52; B: 42.16±11.13; C: 53.92±8.19; D: 53.09±6.29 %; A vs C, D: $p<0.001$; B, vs C, D: $p<0.01$), while there was no difference between groups C and D. Simultaneously, the percentage of CCR4+T memory cells was also found to be significantly lower in groups A and B than in groups C and D (A: 31.53±9.67; B: 31.40±8.14; C: 39.88±9.10; D:40.90±7.24%; A vs C, D and B vs C,D $p<0.01$) also without difference between goups C and D.
Conclusion: Our results have shown that the onset of T1D was associated with the decreases in the CXCR3+ and CCR4+ subsets of T memory lymphocytes, presumably reflecting their extravasation into pancreatic tissue. However, these changes could not be detected in the nondiabetic FDRs, thus implying that the onset of the disease could be modified on the level of these subsets of T memory cells.

PS 23 Inflammatory mediator responses and markers in type 1 diabetes

Systemic cytokines and chemokines in prediction of type 1 diabetes in high risk antibody positive subjects

M.-C. Simon[1], S. Schimmack[1], K. Strassburger[1], M. Roden[1,2], E.A.M. Gale[3], P.J. Bingley[3], T. Mandrup-Poulsen[4,5], H. Kolb[6], N.C. Schloot[1,2], ENDIT Group;
[1]Institute for Clinical Diabetology, German Diabetes Center, Duesseldorf, [2]Clinic for Metabolic Diseases, University Hospital Duesseldorf, Germany, [3]Department of Clinical Science at North Bristol, University of Bristol, United Kingdom, [4]Steno Diabetes Center, Gentofte, [5]Hagedorn Research Institute, Gentofte, Denmark, [6]Medical Faculty, Heinrich-Heine University Düsseldorf, Germany.

Background and aims: Type 1 diabetes is the result of a chronic immune mediated destruction of ß-cells lasting several months to years before manifestation of overt hyperglycemia. Cytokines and chemokines have been shown to orchestrate the immune response and can also directly harm ß-cells and associate with the disease process after diabetes manifestation. This study therefore aimed to evaluate whether systemic concentrations of cytokines and chemokines predict type 1 diabetes.
Materials and methods: Serum samples from baseline visits of 291 first-degree ICA-positive relatives, (55% males / 45% females, age 20±6.1years) of the European Nicotinamide Diabetes Intervention Trial (ENDIT) were analysed for chemokines (IL-8, MIP1-α) and cytokines (MIF, TNF-α, interleukin (IL)-13, IL-1ß, IL-1receptor antagonist [IL-1ra]). The clinical endpoint (overt diabetes mellitus) was monitored during the observational period of 5 years. Subjects were grouped into two age groups, below and above 16 years of age, as disease progression is thought to be faster in younger versus older subjects. Immune-mediators were measured by ELISA based technology. Regression analysis was adjusted for potential confounders sex, age, body mass index (BMI) and nicotinamide treatment.
Results: 73 (25%) subjects were diagnosed with type 1 diabetes during the follow up, with the earliest diabetes manifestation observed after one year and the latest after 5 years. 218 (75%) subjects remained non-diabetic. As known from previous ENDIT analyses, diabetes developed more frequently in pediatric (56 of 138, 41%) than in adults (16 of 153, 10%; p=0.001). Subjects above age 16 showed higher IL1ra concentrations compared to children (239 pg/ml versus 183 pg/ml, p=0.0197). All other immune parameters did not differ between pediatric versus adult subjects. Within the age groups, neither IL1ra, nor IL-8, MIP1-α, MIF, TNF-α, IL-13 or IL-1ß were predictive for later diabetes development.
Conclusion: In our study systemic chemokines, cytokines or cytokine receptor antagonist concentrations obtained one to five years before diabetes onset did not serve as predicitive markers for disease manifestation. The age-associated increase of IL1ra in adult subjects may contribute to the overall reduced rate of diabetes development compared to younger subjects.

447

Proinflammatory and regulatory cytokines are similar in type 1 diabetes (T1D) and LADA and lower compared to type 2 diabetes (T2D) patients: results from Action LADA Study

M.N. Pham[1], M.I. Hawa[2], C. Pfleger[3], M. Roden[1,4], G. Schernthaner[5], P. Pozzilli[6], R. Buzzetti[7], J. Seissler[8], S. Hunter[9], R.D. Leslie[2], N.C. Schloot[1,4], the Action LADA Study Group;
[1]German Diabetes Center, Duesseldorf, Germany, [2]Institute of Cell and Molecular Science, London, United Kingdom, [3]Benaroya Research Institute, Seattle, USA, [4]Clinic for Metabolic Diseases, University Hospital, Duesseldorf, Germany, [5]Rudolfstiftung Hospital, Vienna, Austria, [6]University Campus Bio-Medico, Rome, [7]Dipartimento Scienze Cliniche, Rome, Italy, [8]Ludwig-Maximillians-University, Munich, Germany, [9]Centre for Endocrinology and Diabetes, Belfast, United Kingdom.

Background and aims: LADA (latent autoimmune diabetes in adults) is clinically almost indistinguishable from T2D but has T1D like islet antibodies (GADA). Previous studies showed that cytokines are involved in the pathogenesis of T1D and T2D. As cytokines play an important role in pathogenesis

of T1D and T2D we aimed to search for differences of LADA compared to T1D and T2D.
Material and methods: We investigated systemic cytokines of 90 patients with T1D (F/M= 28/62, age 45±10yrs), 61 LADA patients (35/26, 52±10yrs) positive for GADA who had not required insulin for at least 6 months after diagnosis, 465 T2D patients who were GADA negative (202/263, 55±9yrs) and 41 control subjects (C) (25/16, 47±9yrs). All patients were recruited from the Action LADA cohort with diabetes duration <5yrs. Anti-inflammatory IL-1ra and pro-inflammatory TNF-a and IL-6 from serum samples were measured by multiplex technology. Differences of circulating cytokine concentrations between all groups were assessed using Kruskal-Wallis test followed by Mann-Whitney test. With multiple linear regression models we compared log-transformed systemic cytokine concentrations of different groups as dependent variables using age, sex, BMI, blood pressure (BP) and diabetes duration as covariates.
Results: For all three cytokines significant differences were detected between different groups (all p<0.0001). Group by group comparison revealed similar cytokine concentrations in T1D and LADA patients. Compared with controls, T1D and LADA had significantly up-regulated IL-1ra, IL-6 and TNF-a (p<0.05). When comparing T1D and LADA versus T2D, all three cytokines were significantly higher in T2D (IL-6 p<0.001, TNF-a and IL-1ra p<0.05). As groups differed by BMI, age, sex, BP and disease duration we performed stepwise regression analysis with adjustment for these potential confounders. As expected, systemic concentrations of IL-1ra and IL-6 were positively associated with BMI (p<0.0001). TNF-a did not show an association with BMI. The significant increase of cytokines in T2D versus T1D/ LADA and C found in unadjusted comparisons persisted upon adjustment for sex, age, BMI, BP and diabetes duration in multiple linear regression models (all p<0.05).
Conclusion: We conclude that proinflammatory as well as anti-inflammatory cytokines are elevated in T2D compared to T1D, LADA and C. IL-1ra, IL-6 and TNF-a of LADA were lower compared to T2D but were similar compared to T1D. As cytokines cannot distinguish T1D from LADA, other factors are likely to determine clinical outcome that is characterized in immediate insulin need in T1D and preserved endogenous insulin secretion in LADA. Further studies should investigate which other factors might influence the pathogenic process leading to slower deterioration of ß-cell function in LADA and faster deterioration of ß-cell function in T1D.

448

Serum CXCL1 levels are elevated in subjects with type 1 diabetes mellitus and possibly reflect the rate of c-peptide loss.
K. Takahashi, M. Masaya, T. Takahashi, K. Nagasawa, H. Homma, M. Yamashina, M. Ishii, F. Fujiwara, T. Kajiwara, H. Taneichi, N. Takebe, J. Satoh;
Division of Diabetes and Metabolism, Department of Internal Medicine, Iwate Medical University, Morioka, Japan.

Background and aims: Identification of unique inflammatory biomarkers may improve prediction of type 1 diabetes (T1D), and be used as clinical measures in trials aimed at preventing this disease. We previously compared transcript profiles of bone marrow (BM)-derived dendritic cells (DC) from NOD mice, a model of T1D, with those from a sister strain, NON mice, to characterise molecular changes in BMDC, and then found that BMDC from 4-week-old female NOD displayed 3-5 times stronger expression of inflammatory mediators, including CCL7, CXCL1, CXCL5, and S100A8/100A9, than those from NON. Intriguingly, in the human, these chemokines (Wang X, 2008) and S100 proteins (Collins CD, 2006) have been noted as possible biomarkers reflective of active anti-islet autoimmunity by microarray analyses. In the present study, we investigated weather serum levels of these molecules serve as effective biomarkers for T1DM, and those reflecting active autoimmune process.
Materials and methods: CCL7, CXCL1, CXCL5, and S100A8/100A were quantified by ELISA in sera from Japanese subjects with T1D and T2D as a matched disease control. Serum fasting C-peptide (CPR) levels were measured by CLEIA at the beginning of the study, and followed up after a year. The study groups consisted of: (i) 26 subjects (11 females, 15 males; median age 43 years, range 16-75 years; duration of diabetes 10 years, range 1-40 years) with acute-onset T1D; (ii) 20 subjects (10 female, 10 males; age 69 years, range 38-79 years; duration of diabetes age 10 years, range 3-26 years) with slowly progressive T1D; and (iii) 20 subjects (8 females, 12 males; mean age 10 years, range 21-83 years; duration of diabetes age 10 years, range 1-32 years) with T2D. All T1D subjects were positive for autoantibodies.
Results: It was noted that serum CXCL1 levels were significantly higher in subjects with acute-onset (median 113.2 ng/ml, range 41.75-457.2 ng/ml), and slowly progressive (median 100.8 ng/ml, range 32.87-225.0 ng/ml) T1D than in those with T2D (median 71.58 ng/ml, range 32.45-152.6 ng/ml, p=0.01 and 0.03, respectively, Mann-Whitney U test). Decreases in fasting CPR levels per year were significantly correlated with the CXCL1 levels (n=10, r=-0.01, p=0.02) in the subpopulation of slowly progressive T1D subjects displaying preserved beta-cell function, whereas cross-sectional fasting CPR levels were not. Serum CCL7, CXCL5, and S100A8/100A9 concentrations showed no difference between T1D and T2D subjects.
Conclusion: To our knowledge, this is the first report that reveals T1D subjects display elevated serum CXCL1 levels, irrespective of the subtypes, compared to control T2D subjects. CXCL1 is produced by monocytes and dendritic cells, as well as by beta cells, and reportedly involved in activating Th17 cells which play a pivotal role in developing T1D. The serum concentrations of this chemokine were able to predict the loss of CPR in slowly progressive T1D subjects, possibly reflecting activity of the anti-islet autoimmune process, however, failed to distinguish subtypes of T1D. The predictive value of CXCL1 in the development of acute-onset T1D should be further investigated in the first-degree relatives at risk or the recent onset subjects. In conclusion, we propose that the elevated serum CXCL1 levels are good markers for T1D, predisposing to anti-islet autoimmunity.

449

High risk vs low risk nondiabetic first degree relatives of type 1 diabetics: differences in expression of Th1 and Th2 associated chemokine receptors and chemokine levels
A. Jotic[1], N.M. Lalic[1], T. Milicic[1], I. Markovic[2], M. Zamaklar[1], K. Lalic[1], L. Lukic[1], N. Rajkovic[1], M. Macesic[1], J. Seferovic[1], S. Aleksic[1];
[1]Institute for Endocrinology, Clinical Center of Serbia, [2]Institute for Biochemistry, Belgrade, Serbia.

Background and aims: It has been previously suggested that expression of Th1 and Th2 associated chemokine receptors determine the recruitment of CD4+T cells into sites of inflammation during the onset of Type 1 diabetes (T1D). However, the relevance of the changes in expression of chemokine receptors, CXCR3+ (Th1 associated) and CCR4+ (Th2 associated), on T memory CD4+CD45RO+ cells and in respective chemokine levels, interferon-γ inducible chemokine (IP-10) (Th1 associated), and thymus-and activation-regulated chemokine (TARC) (Th1 associated), for the development of T1D has not yet been elucidated. Therefore, the aim of this study was to compare the changes in (a) percentage of CXCR3+ and CCR4+ subsets of CD4+ T memory cells (b) the level of chemokines IP-10 and TARC, in peripheral blood between two groups, the high-risk and the low-risk group, of nondiabetic first-degree relatives (FDRs) of patients with T1D as well as in the group of healthy controls. The difference between the two groups of FDRs was based on presence or absence of glutamic acid decarboxylase (GADA) and tyrosine phosphatase insulinoma antigen-2 (IA-2) antibodies. Thus, in the study we included 10 high-risk nondiabetic FDRs (GADA+, IA-2+) (group A) and 34 low-risk nondiabetic FDRs (GADA-, IA-2-) (group B) and 18 healthy unrelated control subjects (GADA-, IA-2-) (group C).
Materials and methods: T1D and glucose intolerance were excluded in the study by using WHO criteria. IP-10, TARC, GADA and IA-2 levels were determined by ELISA. The percentages of CD4+CXCR3+ and CD4+CCR4+ T memory cell subsets were analyzed in peripheral blood by using four-color immunofluorescence staining and flow cytometry.
Results: When the percentage of CXCR3+ T memory cells was analyzed, it was found to be higher in group A vs groups B and C (A: 64.27±6.53 vs B: 51.79±6.79; C: 53.09±6.29%, p<0.05). Simultaneously, the level of IP-10 was higher in group A vs groups B and C (A: 154.56±112.99 vs B: 109.73±79.52; C: 85.24±19.82 pg/ml, p<0.05). In contrast, the percentage of CCR4+ T memory cells was significantly lower in group A vs groups B and C (A: 30.04±3.26 vs B 41.90±8.59; C: 40.90±7.24 %, p<0.05). However, when TARC level was tested, it was similar in group A in comparison to group B and did not differ significantly compared to group C (A: 406.66±171.44 vs B: 336.01±166.26; C: 236.88±89.19 pg/ml, p=NS).
Conclusion: Our results have demonstrated that high risk FDRs showed higher levels of CXCR3+ T cell subset and IP-10 chemokine, both associated with increased Th1 response, together with lower levels of CCR4+ Th2 cell subset. The results imply that in FDRs the risk for developing T1D might be strongly influenced by enhanced activity of Th1 and diminished activity of Th2 autoimmune response.

The association between vitamin D levels and biomarkers in newly diagnosed children with diabetes and their siblings

J. Svensson[1], H.B. Mortensen[1], J. Johannesen[1,2], M. Fenger[3], A. Linneberg[2,3]; [1]Dept. of Paediatrics, Glostrup University Hospital, [2]Glostrup University Hospital, [3]Hvidovre University Hospital, Denmark.

Background and aims: Vitamin D insufficiency has been suspected as a contributing factor to the development of type 1 diabetes. Different cells in the immune system are capable of converting 25-OH to its active form 1,25 OH and vitamin D has been shown to suppress Th1 cytokines and enhance Th2 cytokines. The aim of the present study was to investigate the association between levels of vitamin D and different cytokines and chemokines.
Materials and methods: Data is derived from *The Danish Diabetes Registry* (*DIA-REG B&U*) initiated in 1996 with an attached bio bank. All serum samples were analysed using high-capacity Luminex xMAP technology. Vitamin D is determined by HPLC and divided in quartiles. Data was analysed using multiple regression with biomarkers as outcome and vitamin D in quartiles and CYP27B1 genotype as explanatory variables together with age and gender. All children were genotyped for the CYP27B1 variant rs4646536.
Results: There were 466 newly diagnosed children with diabetes and 466 healthy siblings. 509 were males and 423 females. We found no difference in vitamin D level between patients and siblings. CXCL8 (0.34 +/- 0.12; p<0.001), IL-4 (0.12 +/- 0.04; p=0.01), IL-18 (0.03 +/- 0.028; p=0.03) and IL-1b (0.20 +/- 0.11; p<0.001) significantly increased with increasing vitamin D level in the joined analysis of patients and siblings, when only patients were analysed CXCL8 (0.20 +/- 0.17; p=0.02), IL-18 (0.07 +/- 0.04; p<0.001) and IL-1b (0.16 +/- 0.15; p=0.04) were still positively associated with vitamin D. No association was found with IL-10, IL-12, IFN-g and TGF-b. Only for IL-1b and IL-18 there was a significant association with CYP27B1 genotype
Conclusion: We found no indication of suppressed Th1 and enhanced Th2 in either patients or healthy siblings with high levels of vitamin D but on the contrary increasing levels of Th1 oriented cytokines/chemokine IL-1b, IL-8, CXCL8 and Th2 oriented cytokine IL-4 with each quartile in vitamin D. The effect of vitamin D in relation to onset may be questioned.

MicroRNA profiling from peripheral blood of diabetic patients

C.M. Khoo, A. Armugam, P. Swaminathan, P. Lim, K. Jeyaseelan; National University Health System, Singapore.

Background and aims: MicroRNAs (miRNAs) play important roles in post-transcriptional control of gene expression. While specific miRNAs are implicated in several disease processes including type 2 diabetes (DM), few have been evaluated and validated in humans. We therefore profiled the miRNA expression from the peripheral blood of type 2 DM patients.
Materials and methods: We compared 12 DM male subjects with 12 healthy male controls. They were well matched in age [mean(SD) 37.3 (7.1) yrs] and body mass index [mean(SD) 26.1 (5.6) kg/m^2]. Blood pressure (BP) and fasting blood for glucose, lipids and HbA1c were measured. Total RNA was extracted from peripheral blood for miRNA profiling and real-time PCR analysis. The signal log ratio and p-values were calculated. T-test was used to compare DM subjects with controls.
Results: Systolic BP, fasting glucose, HbA1c, total cholesterol and LDL-cholesterol levels were significantly higher in DM subjects compared with controls (all P<0.05). Compared with controls, we identified 37 differentially regulated miRNAs in DM subjects. Among them, 21 miRNAs were upregulated (two to five-fold change, P<0.01) and 16 miRNAs were downregulated (1.5 to two-fold change, P<0.01). These miRNAs are primarily involved in regulating pancreatic development and functions, adipocyte differentiation, insulin signaling and glucose-dependent insulin secretion.
Conclusion: We have found several differentially expressed miRNAs from the peripheral blood of DM patients that are involved in glucose homeostasis and related functions. These miRNAs can be used as markers of disease progression and may be developed for therapeutic applications in DM.

Virus-induced beta cell death depends on CXCL10 and the AKT-JNK-PKR crosstalk

E. Domsgen[1], F. Paroni[1], J. Kerr-Conte[2], A. Dotzauer[1], K. Maedler[1]; [1]Centre for Biomolecular Interactions, University of Bremen, Germany, [2]INSERM /Université de Lille, Thérapie Cellulaire du Diabète, France.

Background and aims: Both, type 1 (T1DM) and type 2 diabetes (T2DM) result from β-cell destruction and decreased β-cell mass. Virus infection seems to be an important environmental factor for the development and progression of the disease. Group B coxsackievirus (CVB) infection of β-cells has been associated with the development of diabetes. Intra-islet viral particles have been detected in pancreata from patients with T1DM and T2DM, but the mechanisms of a correlation between virus infection and diabetes progression are poorly understood. In this study we asked the question whether virus induced cytokines and chemokines correlate with β-cell destruction and which intracellular signals are involved.
Materials and methods: Isolated human islets and the CM human β-cell line were infected with two different CVB serotypes B3 and B4. Replication of CVB was confirmed by immunostaining of viral protein 1 (VP1) and titration of islet lysates. CXCL10 secretion from the islets was measured by ELISA, CXCL10, IFNβ, IFNγ, IL-1β, TNFα, IL-6, MCP1 and IL-8 mRNA production by quantitative RT-PCR and β-cell apoptosis by double-staining for the TUNEL assay and insulin. Islet protein expression and phosphorylation were analyzed by western blot.
Results: CVB3 and CVB4 infection of isolated human islets and β-cells induced a high virus replication, VP1 positive staining in up to 70% of the β-cells and resulted in a 7-fold increase in β-cell apoptosis in both the CVB3 and -4 infected islets together with an abolished glucose stimulated insulin secretion. This correlated with the increase in CXCL10, IFNβ, IL-1β, TNFα, IL-6, MCP1 and IL-8 mRNA levels in the infected islets. CXCL10 was the highest induced factor (~35-fold increase in secretion, 15-fold increase in mRNA, p<0.001), compared to uninfected islets. In contrast, IFNγ remained unchanged, suggesting that CXCL10 upregulation was independent of the known induction pathway. To determine the host cell pathways involved in CVB infection, we analyzed the kinetics of pro- and anti-apoptotic signals. We have previously shown, that CXCL10 induces transient Akt phosphorylation despite massive induction of β-cell apoptosis. In line with this data, Akt was also activated during CVB infection within 30 minutes p.i. and lasted for up to 24 h. After 24 h, Akt was downregulated together with an up-regulation of phospho c-Jun NH2-terminal kinase (pJNK), activation of Caspase-3, strong induction of CXCL10 and the appearance of VP1, switching survival signals into apoptosis. A link of such pro-inflammatory signals and viral infections is provided by double-stranded RNA-dependent protein kinase R (pPKR). Both virus strains lead to phosphorylation of PKR as well as its substrate eIF2α in islets. Blocking PKR phosphorylation by 2-aminopurine lead to a decreased VP1 expression.
Conclusion: Our data show that CBV infections have a direct deleterious effect on β-cell survival, resulting from virus-induced activation of pro-inflammatory cytokines and chemokines. During the early phase of infection, the virus triggers the Akt pathway, possibly to initially maintain host survival and its own replication. Antagonism by JNK and PKR phosphorylation would switch β-cell pro-survival paths into death. Further understanding of the pathways involved in viral infection of β-cells will be of particular interest in order to develop new therapies to rescue the β-cell.

Coxsackievirus B3 induces the mRNA expression of IFNbeta and viral recognition receptors in human pancreatic islets

K. Lind[1], P.G. Larsson[1], M. Hühn[1], O. Korsgren[2], M. Flodström-Tullberg[1]; [1]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, [2]Department of Clinical Immunology, Uppsala University, Sweden.

Background and aims: Many observations have suggested a role for enterovirus infections, especially those with Coxsackieviruses (CV), in the etiopathogenesis of type 1 diabetes (T1D). Enteroviruses may contribute to T1D development by inducing functional impairment of beta cell functions, and/or beta cell destruction. An important immune response upon infection is the rapid production of type 1 interferons (IFNs) that inhibit viral spread and facilitate viral clearance. Interferon production is initiated via viral recognition by pattern recognition receptors. Cellular detection of RNA viruses

is mainly dependent on two receptor families, the toll-like receptors (TLRs) including TLR3, 7 and 8, and the cytoplasmic retinoic acid-inducible gene I -like helicases (RLHs) including melanoma differentiation associated gene 5 (MDA5) and retinoic-acid-inducible protein I (RIG-I). Stimulation of these sensors trigger the production of pro-inflammatory cytokines and type I IFNs. The aim of this study was to investigate the expression of intracellular viral sensors and IFNβ in human pancreatic islet cells infected with CV.
Material and method: Human islets from 20 donors were obtained from the Nordic Network for Clinical Islet Transplantation. The mRNA expressions of IFNβ, MDA5, RIG-I, TLR3, 7 and 8 were measured in human islets 48 h after infection with CV serotype B3 (CVB3) using quantitative Real-Time PCR analysis.
Results: Human islets responded to a CVB3 infection by upregulating the mRNA expression of IFNβ ($p<0.0005$ vs. uninfected control). Moreover, there was a significant upregulation of the mRNA expression for the intracellular viral sensors MDA5, RIG-I and TLR3 ($p<0.01$, 0.005, 0.005, vs. uninfected control, respectively). A small, but not significant, upregulation of TLR7 and TLR8 mRNAs was also observed ($p=0.16$ and 0.21, vs. uninfected controls, respectively).
Conclusion: Our results show that human pancreatic islet cells express low basal levels of intracellular viral sensors and IFNβ, which are robustly induced upon CVB3 infection. Mounting an antiviral response rapidly upon infection might be important for beta cell survival and protection against virus induced type 1 diabetes.

Role of STAT-1 and IRF-1 in cytokine-mediated dysfunction and apoptosis in mouse islets of Langerhans
L. Overbergh[1], W. D'Hertog[1], C. Gysemans[1], D.L. Eizirik[2], E. Waelkens[3], C. Mathieu[1];
[1]LEGENDO, Catholic University of Leuven, [2]Laboratory for Experimental Medicine, Université Libre de Bruxelles, [3]Laboratory of Protein Phosphorylation and Proteomics, Catholic University of Leuven, Belgium.

Background and aims: Type 1 diabetes (T1D) is an autoimmune disease characterized by a T-cell mediated destruction of the pancreatic beta cells. Cytokines, such as IL-1β and IFN-γ, play a crucial role in beta cell destruction, by activating two different pathways, NF-κB and JAK/STAT, among others. Previous work from our group discovered a dual role for the IFN-γ signaling pathway. If the pathway was interrupted at the level of STAT-1, islets and purified beta cells were fully protected against cytokine-induced apoptosis; however, deletion of the direct downstream effector gene of STAT-1, IRF-1, showed a dual response. Thus, whole mouse islets were partially protected *in vitro*, while purified beta cells demonstrated no difference in protection against cytokine-induced apoptosis, suggesting a role for non-beta cells in the islets in this destruction. *In vivo*, IRF-1 deletion in islets was associated with a higher prevalence of primary non-function and shorter functioning graft survival. In the present study, we aimed to study the protein profiles in islets with a disruption of either transcription factor exposed to inflammatory cytokines.
Materials and methods: Alterations in protein profile upon cytokine-treatment were investigated in islets from C57BL/6, STAT-$1^{-/-}$ or IRF-$1^{-/-}$ mice after 24h incubation with/without a combination of IFN-γ (1000 U/ml) and IL-1β (50 U/ml). Differential protein expression was analyzed using 2-dimensional difference gel electrophoresis (2D-DIGE) and differentially expressed spots were identified by MALDI-TOF/TOF. In parallel, susceptibility to apoptosis was measured by microscopic counting (Hoechst/PI staining).
Results: While the combined treatment of IL-1β + IFN-γ clearly caused apoptosis in C57BL/6 islets (40.6±3.7%, similar to 5.6±1.1% apoptosis for non-treated islets, $p<0.001$, $n=12$), STAT-$1^{-/-}$ islets were completely protected against cytokine-induced apoptosis (4.6±0.3% compared to 5.0±0.7% for non-treated islets ($n=10$)) and IRF-$1^{-/-}$ islets were partially protected (25.1±4.4% compared to 5.1±0.7% for non-treated islets ($p<0.001$, $n=9$)). 2D-DIGE analysis, revealed a total of 1853 spots, of which 301 were differentially expressed ($p<0.05$, $n=4$). Of these, we identified by now 144 spots. 60% of these were exclusively regulated in the C57BL/6 islets, with identified proteins belonging to different functional groups such as mRNA processing, insulin signaling, metabolism and folding of proteins. Treatment with cytokines generated far less response in the proteome of STAT-$1^{-/-}$ and IRF-$1^{-/-}$ islets. Moreover, the proteomic response generated in the knock-out mouse islets was indicative for unique effects of *Stat1* or *Irf1* gene disruption. An example is heat shock 70 kDa protein 9 (GRP75), which had markedly lower levels in IRF-$1^{-/-}$ islets and higher levels in STAT-$1^{-/-}$ islets, as compared to control C57BL/6 islets ($p<0.05$).
Conclusion: We identified proteins whose regulation was not only dependent on STAT-1 and/or IRF-1, but whose functionality can explain the difference in sensitivity of these islets to cytokine-induced cell death. These proteins could be important targets for clinical intervention in T1D, as disruption of the JAK/STAT pathway is not a feasible option for treatment or prevention of T1D.

T cell function is released from the anti-inflammatory effects of adiponectin in type 1 diabetes (T1D): a potential link between insulin resistance (IR) and T1D
T.T.L. Pang, M. Chimem, E. Goble, S.A. Eldershaw, P. Narendran;
School of Clinical and Experimental Medicine, University of Birmingham, United Kingdom.

Background and aims: IR is independently associated with the development of T1D, though the mechanism for this is not clear. Adiponectin is an insulin sensitising and anti-inflammatory adipokine whose serum levels are reduced with IR. We hypothesised that changes in adiponectin and its receptors may mediate the link between IR and T1D. We have previously shown that receptors for adiponectin, AdipoR1 & AdipoR2, are expressed by peripheral blood mononuclear cells (PBMC), and in particular by monocytes and CD11c+ CD1a+ dendritic cells (DC). We also found the monocytic expression of AdipoR1 & AdipoR2 is reduced by 45% ($p<0.01$) in patients with T1D, compared to matched healthy controls as well as subjects with insulin treated type 2 diabetes. In this present study, we determined the effect of adiponectin on DC-mediated T cell proliferation, as well as the functional significance of the reduced AdipoR expression in T1D.
Materials and methods: 10 subjects with T1D were compared against 10 age and BMI-matched healthy controls. AdipoR1 & AdipoR2 expression was measured by flow cytometry and qPCR. In serum-free conditions, we studied changes in the expression of CD80, CD86, HLA-DR, CD1a, DC-SIGN on monocyte-derived DC, following exposure to adiponectin. The stimulatory capacity of DC on T cells and whole PBMC proliferation was assessed by CFSE dilution.
Results: The addition of adiponectin to CD14+ monocytes decreased the expression of CD86 on DC at both RNA and protein level by 39-64%. This inhibitory effect on CD86 was dose dependent (IC50 = 1.3-1.9 ug/ml). This pronounced effect was not observed when adponectin was added at >24 hours of DC culture and was overcome by LPS added on day 5. The expression of CD1a, DC-SIGN, HLA-DR & CD80 did not alter. DC generated in the presence of adiponectin showed reduced stimulatory capacity when tested on CFSE+CD4+CD25- effector T cells. In T1D, adiponectin induced suppression of CD86 expression at the fixed dose of 10ug/ml was significantly decreased in T1D by up to 31% (IC50 = 1.55-2.08 ug/ml $p<0.05$). The degree of inhibition correlated with AdipoR1 protein expression of the monocyte precursors ($r=-0.69$ $p<0.05$). Furthermore, adiponectin treated DC from T1D subjects retained greater T cell stimulatory capacity, in the presence of OKT3. In corroboration, the suppression of PBMC proliferation by adiponectin to the common antigen tetanus toxoid was also significantly reduced in T1D (Healthy controls 48% vs 25% in T1D $p<0.05$).
Conclusion: T cells are released from the anti-inflammatory effects of adiponectin in patients with T1D. This mechanism may contribute to the association between IR and the development of T1D.

Preservation of beta cell function by treatment with DiaPep277® - a retrospective analysis of phase II data in adult type 1 diabetes patients

S. Dagan[1], D. Elias[1], M. Tamir[1], A. Avron[1], G. Harari[2], I. Raz[3], 352 Study Group, 520 Study Group;
[1]Andromeda Biotech Ltd., Yavne, [2]MediStat Ltd., Tel Aviv, [3]Hadassah Center for the Prevention of Diabetes, Hadassah University Hospital, Jerusalem, Israel.

Background and aims: DiaPep277®, a peptide derived from the human Hsp60, modulates the immunological destruction of β cells that lead to autoimmune diabetes. Several phase II studies (352, 420, 441/451, 520) were conducted to evaluate the ability of DiaPep277® to preserve insulin secretion in adult type 1 diabetes (T1D) patients. Due to the small number of patients and the diversity in β cell function among T1D patients, a statistically significant difference could be demonstrated only for one study (420) despite the similarity in trend analysis in all 4 studies analyzed. To evaluate the efficacy of DiaPep277® in a larger number of patients, we performed a retrospective combined data meta analysis of the efficacy parameters.
Materials and methods: To compensate for the small group size in the individual studies, the efficacy data of studies 352, 420, 441/451, and 520 were pooled and analyzed. This is justifiable in view of the comparable demographic data. Patients were treated for 12 months and C-peptide levels were measured at month 13 and at month 18 (6 months after end of treatment, excluding study 441/451). Preservation of β cell function was evaluated as the change in total secreted C-peptide (AUC) following glucagon stimulation from Baseline to 13 and 18 months.
Results: A significant preservation of β cell function in patients treated with 1.0 mg DiaPep277® was demonstrated. At the end of treatment, the change in glucagon stimulated C-peptide AUC in the DiaPep277® treated group (n=58) was -0.36 nmol/l/min as compared to -2.79 nmol/l/min in the placebo group (n=46) (p=0.028). At the end of follow-up, although C-peptide values had declined in both arms, the decrease in the DiaPep277® arm was significantly smaller than that in the placebo arm, -2.28 ± 5.4 nmol/l/min versus -5.56 ± 7.0 nmol/l/min, respectively (p=0.04). This decrease may indicate that the treatment of adult patients should be longer than 1 year to maintain treatment effect. In addition, DiaPep277® treatment improved the ability to maintain the ADA-recommended HbA1c target of <7%. At the end of follow-up, 64% of DiaPep277® treated subjects reached the target glycemic level compared to only 47% in the placebo group.
Conclusion: The combined data analysis of the phase II studies in adult T1D patients showed a statistically significant treatment effect of preservation of β cell function and clinical benefit of improved glycemic control. This clearly indicates that the lack of conclusive difference in the individual studies stems from the small number of patients per arm and not from a limited treatment effect. Based on these results, 2 phase III studies are being conducted worldwide in newly diagnosed adult T1D patients to obtain regulatory approval for registration.

Phase II clinical studies in T1D subjects - Baseline demographic data (average ± SD)

	Study 352	Study 420	Study 441/451	Study 520

CoQ10 affects peripheral natural killer cells in patients with type 1 diabetes mellitus

J. Grünler[1], G. Dallner[1], K. Brismar[1], A. Brauner[2], H. Brauner[2];
[1]Department of Molecular Medicine and Surgery, [2]Department of Microbiology, Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden.

Background and aims: Natural killer (NK) cells have been implied in the pathogenesis of type 1 diabetes (T1D), although their exact role in the disease is still not known. T1D leads to long term complications, including increased mortality mainly due to cardiovascular disease (CVD). The antioxidant CoenzymeQ10 (CoQ10) has been suggested to decrease CVD risk by a mainly unknown mechanism. We here, for the first time, investigate the impact of CoQ10 treatment on the NK cells in T1D.
Materials and methods: Patient data and peripheral blood samples were collected immediately before and after 12 weeks of oral CoQ10 treatment (100 mg twice daily). Peripheral blood mononuclear cells (PBMC) were analysed using flow cytometry after staining with monoclonal antibodies. The NK cells were defined as $CD56^{+}CD3^{-}$ lymphocytes. NK cell frequency, subset distribution and phenotype in patients with T1D was compared with patients with type 2 (T2D) diabetes as controls since they too exhibit chronic hyperglycaemia, which by itself could influence lymphocyte phenotype and function, but lack the autoimmune pathology of particular interest to this study. 13 T1D and 10 T2D patients (mean age 58.1 ± 9.8 vs 62.8 ± 8.9 yrs, females 54 vs 30%, fasting plasma glucose 7.2±1.3 vs 6.9±3.3 mM p=0.27, HbA1c 6.7±1.3 vs 5.6 ±1.1, none significantly different) were treated 12 weeks with CoQ10. Retinopathy was more common in T1D (92 vs 40%, p= 0.02) while nephropathy was more common, although not significantly, in T2D patients (30 vs 8%). No difference was observed regarding neuropathy.
Results: Treatment with CoQ10 did not affect the overall frequency of NK cells in PBMC, in T1D or T2D patients. However, several phenotypic alterations of the peripheral pool of NK cells were observed after CoQ10 treatment. The NK cell activating receptor NKG2D has previously been shown to be downregulated in NK cells from T1D patients. Here we show that CoQ10 leads to a small but highly significant (p<0.001) upregulation of NKG2D on NK cells in T1D, hence potentially normalizing the NKG2D levels. Some NKG2D ligands are upregulated in response to stress and NKG2D has been implicated in several pathological conditions. We also observed an increased subset of CD11c expressing NK cells, both among the T1D and T2D (p<0.01 and p<0.05 respectively) after treatment. CD11c positive NK cells have been demonstrated to be potent cytokine producers and might interact in long term complications. NK cells are divided into two phenotypically and functionally distinct subsets on the basis of their expression level of the surface marker CD56. While NK cells with a bright expression of CD56 have a higher capacity to produce cytokines, the CD56 dim NK cells are more cytotoxic. In patient with T1D, we found a significant increase of CD56 bright NK cells after CoQ10 treatment. A similar trend was observed also in T2D. This finding further supports the idea that cytokine producing NK cells are increased in peripheral blood following CoQ10.
Conclusion: Our results demonstrate that CoQ10 treatment increased NK cells expressing CD11c in both T1D and T2D, as well as the percentage of CD56 bright NK cells and the activating receptor NKG2D in T1D. Collectively our results opens up for a possible role of NK cells in a CoQ10 mediated beneficial effect in patients with T1D.

Does immune tolerance with Alum-GAD prevent or delay onset of type 1 diabetes in non-diabetic children with multiple islet autoantibodies?

H. Elding Larsson[1], C. Andersson[1], A. Carlsson[2], E. Cedervall[3], G. Hansson[1], S.A. Ivarsson[1], B. Jönsson[4], K. Larsson[5], Å. Lernmark[1], J. Neiderud[6], C. Nilsson[1], for the DiAPREV-IT Study Group;
[1]Department of Clinical Sciences, Malmö, [2]Pediatrics, Lund, [3]Pediatrics, Ängelholm, [4]Pediatrics, Ystad, [5]Pediatrics, Kristianstad, [6]Pediatrics, Helsingborg, Sweden.

Background and aims: Type 1-diabetes (T1D) is predictable by HLA-risk genotypes and islet autoantibodies. The subclinical phase, lasting months to years, is defined by islet autoantibodies (A) against GAD65 (GADA), insulinoma-associated protein 2 (IA-2A), insulin (IAA) or the ZnT8 transporter (ZnT8A). A gradually deteriorating glucose metabolism precede clinical

onset. Children with genetic risk of T1D are followed prospectively by us in the Diabetes Prediction in Skåne (DiPiS) and The Environmental Determinants of Diabetes in the Young (TEDDY) studies. Immune tolerance with human recombinant GAD65 formulated with alum (Alum-GAD) has shown promising results to preserve residual beta-cell function in newly diagnosed T1D children. As only a fraction of the residual beta-cell function remains at onset, we initiated Diabetes Prevention -Immune Tolerance (DiAPREV-IT) as a first prevention study with Alum-GAD. The aim is to evaluate safety and efficacy of Alum-GAD in non-diabetic children from 4 years of age with multiple islet autoantibodies.

Materials and methods: DiAPREV-IT is an investigator-initiated, placebo-controlled, double-blinded study of Alum-GAD (donated by Diamyd Medical AB, Sweden) in children with GADA and at least one additional islet autoantibody. Children from 4 years of age (n=50) recruited from DiPiS and TEDDY will be treated with placebo (n=25) or Alum-GAD (n=25) in two doses of 20 microgram. The children are followed every 3rd month during the 5 year follow-up with alternating IVGTT and OGTT to evaluate beta-cell function. Placebo children developing T1D during the study period will be treated with Alum-GAD at clinical onset. GADA, IA-2A, IAA and ZnT8A (both ZnT8RA and ZnT8WA) are measured by standardised radioimmunoassays.

Results: As of April 1, 2010, a total of 26 islet autoantibody-positive children have been screened for participation. Of those, three children had lost GADA or the additional islet autoantibody at screening. One family withdrew their consent and another child was excluded due to illness. The included 21 children were 4-9.8 (mean 6.0) years old. All but one child (20/21) were positive for one or two of ZnT8R/WA and 17/21 were positive for IA-2A. While 2/21 children were positive for GADA and only one additional autoantibody, the remaining 19 children were positive for 3, 4 or 5 autoantibodies. A total of 17 children have received both injections, and an additional two children have received the first injection. The first visit after the second injection has been completed by 14 children. No serious adverse events were reported and none of the children have developed T1D. Mild to moderate injection site reactions were reported by all participants.

Conclusion: DIAPREV-IT is the first prevention study with Alum-GAD in non-diabetic children with multiple islet autoantibodies. In including analysis of the ZnT8RWA the number of T1D-risk children is increased. As no serious adverse events have been reported so far, DIAPREV-IT will continue to recruit children.

Prediction of remission after 6 months and residual beta cell function 12 months after diagnosis in Danish children using multivariate statistical methods

M.-L.M. Andersen[1], M.A. Rasmussen[2], S. Pörksen[1], L.B. Nielsen[1], J. Svensson[1], J.V. Jørgensen[3], J. Thomsen[4], N.T. Hertel[5], J.S. Petersen[6], A.E. Karlsen[6], L. Hansen[1], H.B. Mortensen[1];
[1]Pediatrics, Herlev University Hospital, [2]Quality and Technology, Dep. of Food Science, Copenhagen, [3]Pediatrics, Skejby University Hospital, Aarhus, [4]Pediatrics, Kolding Hospital, [5]Pediatrics, Odense University Hospital, [6]Department of Diabetes Research Unit, Novo Nordisk A/S, Maaloev, Denmark.

Background and aims: Children and adolescents with newly diagnosed type 1 diabetes (T1D) experience a remission period, where the requirement for exogenous insulin treatment declines or even becomes non-existent. The purpose of this prospective study, conducted in a Danish cohort of children with new onset T1D, is to identify patterns of early clinical and laboratory characteristics and to explore the metabolic disturbance and genetic background as predictors of the residual beta-cell function and remission the first 12 months after diagnosis.

Materials and methods: 129 children and adolescents aged < 17 years from 4 centres in Denmark with newly diagnosed T1D were followed for 12 months. HbA1c, autoantibodies, HLA typing and mixed meal stimulated C-peptide, proinsulin, Glp-1, GIP and Glucagon 1, 3, 6, 12 months after diagnosis were analyzed centrally. pH and standard bicarbonate were determined locally. In addition 40 SNPs in either T1D or T2D related genes have been genotyped. Regression models for prediction of log (C-peptide), and insulin dose adjusted HbA1c (IDAA1c) at 12 months was done by 10 fold cross validated Lasso for variable selection followed by Multiple Linear Regression (MLR) analysis on these relatively few selected variables. Covariates for age, gender and the clinical- and laboratory data were included in the analysis. Data is initially split randomly into 70% training data and 30% test data in order to estimate model performance from independent data. Statistical inference is reported for the test set.

Results: The best predictors for stimulated C-peptide concentration at 12 months were HbA1c at diagnosis (positive association (PA)), C-peptide at 1, 3, and 6 months (PA), IDAA1c at 3 months (negative association (NA)) and proinsulin at 6 months (PA). The selected variables are consistent over time, the model performance slightly improves when data are included over the different time points (r=0.74 0, 1 month data; r=0.79 0, 1, 3 months data and r=0.84 0, 1, 3, 6 months data) and all models are significant (p<0.001). Genotypes of common variants in the PTPN22 and TCF2 genes refine the C-peptide models, but they do not have a significant quantitative impact. HLA risk groups and autoantibodies were not selected by the models. The best predictors for remission after 6 months are C-peptide at 1 month (NA), stimulated blood glucose at 1 month (PA) and height at 1 month (NA), probably a surrogate marker for beta-cell mass. This model is significant (p=0.007, r=0.42) both when we use IDAA1c ≤ 9, to define partial remission (stimulated C-peptide > 300 pmol/l) and IDAA1c as a continuous variable (p=0.013, r=0.41).

Conclusion: This study illustrates the strength of multivariate statistical analysis when applied to observational data, in predicting the course of the residual beta-cell function and remission in children with new-onset T1D. The results suggest that disease progression and proportion of patients in remission can be predicted by objective factors present soon or later after diagnosis.

Fasting and stimulated C-peptide at aseline in DEFEND-1, a phase 3 study of otelixizumab in new onset type 1 diabetes

P. Pozzilli[1], G. Ghirlanda[2], A.M. Brennan[3], B. Belanger[3], C.M. McKee[3];
[1]Endocrinology and Diabetes, Università Campus Biomedico, Rome, [2]Endocrinology and Diabetes, Universita Cattolica del Sacro Cuore, Rome, Italy, [3]Tolerx, Cambridge, USA.

Background and aims: Stimulated C-peptide is frequently used to determine residual beta cell function. We compared mixed meal-stimulated and fasting C-peptide levels using baseline data from the DEFEND-1 Phase 3 study, and investigated the optimal single time point post-meal for determining maximum C-peptide in adults and adolescents with new onset type 1 diabetes mellitus (NOT1DM).

Materials and methods: DEFEND-1 is a multinational, placebo-controlled Phase 3 study of the safety and efficacy of otelixizumab, an investigational Fc-disabled anti-CD3 monoclonal antibody with T cell immunomodulatory activity, in subjects with NOT1DM (clinical trials identifier NCT00678886). Subjects were 12-45 years old, enrolled within 90 days of diagnosis, had BMI < 32, had at least 1 T1DM-associated autoantibody, and were otherwise healthy. Adult subjects had a mixed meal tolerance test (MMTT) with BOOST® at screening and another MMTT at predose (≤ 14 days before the first dose of study drug); subjects < 18 years had a single C-peptide assessment at 120 min post-meal at screening and a full MMTT at predose. To be eligible for DEFEND-1, subjects had to have a maximum stimulated C-peptide > 0.20 nmol/L at screening or predose. The current analysis includes data from one MMTT per subject: the predose MMTT if available, otherwise the screening MMTT.

Results: Data were available from 243 adult and 29 adolescent subjects who went on to receive either otelixizumab or placebo and 101 adults and 8 adolescents who failed screening. Baseline characteristics are shown in Table 1. Fasting and stimulated C-peptide values were available for 339 subjects. Fasting C-peptide was highly correlated with maximum stimulated C-peptide (r=0.76, p=<0.0001) and age group had no significant effect on this association. In adults, a fasting C-peptide > 0.1 nmol/L had a sensitivity of 88% and a specificity of 75% to identify subjects with a maximum stimulated C-peptide > 0.2 nmol/L. In adolescents, the same cutoff value had a sensitivity of 78% to identify subjects with a maximum stimulated C-peptide > 0.2 nmol/L; specificity could not be determined, as no adolescents had a maximum stimulated C-peptide < 0.2 nmol/L. Maximum stimulated C-peptide occurred at 120 min in most subjects (42%); maximum values occurred at 30, 60, and 90 min in 5%, 16%, and 35% of subjects, respectively. Of the 334 subjects with a recorded C-peptide at 120 min, 326 had a maximum stimulated C-peptide > 0.2 nmol/L; of these, only 2 (0.6%) had C-peptide < 0.2 nmol/L at 120 min.

Conclusion: In these subjects with NOT1DM, a fasting C-peptide level of > 0.1 nmol/L was a reasonable determinant of residual beta cell function and, when combined with a single 120 minute post-meal sample for subjects who fall below this threshold, captured 99% of subjects compared with a full

MMTT. These data are of relevance for future trials and interventions in this population.

DIA-AID 1 - An international phase III clinical study to evaluate the biological effect of DiaPep277® in preservation of beta cell function in newly diagnosed T1D patients

A.-G. Ziegler[1], D. Elias[2], S. Dagan[2], I. Raz[3], DIA-AID 1 Study Group;
[1]Institut für Diabetesforschung an der Klinik und Hochschulambulanz für Kinder, Munchen, Germany, [2]Andromeda Biotech Ltd., Yavne, [3]Hadassah Center for the Prevention of Diabetes, Hadassah University Hospital, Jerusalem, Israel.

Background and aims: DiaPep277®, a peptide derived from the human Hsp60, modulates the immunological destruction of β cells that lead to autoimmune diabetes. Following phase II studies which demonstrated good safety and tolerability and preservation of β cell function after treatment with DiaPep277®, a phase III study was initiated and is currently being conducted in 40 medical centers in Europe, South Africa and Israel. The goal is to evaluate safety and therapeutic effect of DiaPep277® in preserving insulin secreting β cells in newly diagnosed type 1 diabetes (T1D) patients.
Materials and methods: The study is randomized, double blinded, placebo controlled. Major inclusion criteria: Age 16 - 45, diagnosed within 3 months, fasting C-peptide > 0.2 nmol/L and positive islet autoantibodies. Subjects received 1 mg DiaPep277® or placebo at 0, 1, 3, 6, 9, 12, 15, 18, and 21 months. Co-primary endpoints were defined as the change in total secreted C-peptide (AUC) measured by the glucagon stimulation test and by the mixed meal tolerance test. Secondary endpoints included glycemic control, daily dose insulin requirement and number of hypoglycemic events as determined by continuous glucose monitoring system. Clinical safety was monitored by electrocardiogram, blood chemistry and haematology. Immune monitoring included peptide-specific dermal sensitivity, antibody titers, cytokine and chemokine profiles and cell surface markers in a population sub-group.
Results: Out of 688 patients screened, 457 were randomized to the study. 221 patients have completed 2 years of therapy and 163 patients are still under treatment protocol. Screening failures were mostly due to fasting C-peptide levels being below the limit (18%) and to an absence of autoantibodies (14%). 16% of the randomized patients dropped out of the study, mostly because withdrawal of consent. Glycemic control was maintained during the treatment period. The mean value of HbA1c at baseline was 7.38% (n=457), at 12 months 7.2% (n=347) and at 24 months 7.46% (n=221). An independent committee that reviews the safety data every six months reported no drug-related safety concerns. Long term safety and treatment effect of DiaPep277® is being followed in an extension study in which patients are divided into a treatment arm and a follow-up arm.
Conclusion: Based on the efficacy and safety data from phase II studies, we designed a phase III clinical study in newly diagnosed T1D patients who are treated with 1 mg DiaPep277® for 2 years. Currently, 51% of the patients have completed 2 years of therapy. Safety evaluation indicates a very favorable safety profile. Results of the study are expected at the end of 2011. A second, confirmatory phase III clinical study is being initiated worldwide in newly diagnosed adult T1D patients.

Clinical and metabolic parameters of patients with T1D randomized into the study at baseline. Data is shown as average + SD and interquartile range (in brackets)

Age	27.15 ± 7.93 (20 - 32)
Gender	302 Males / 155 Females
BMI	24.08 ± 3.42 (21.6 - 26.09)
Fasting C-peptide	0.47 ± 0.25 (0.3 - 0.55)
%HbA1c	7.38 ± 1.7 (6.2 - 8.1)
Insulin U/kg/day	0.4 ± 0.24 (0.25 - 0.52)
Autoantibodies	IA2A+ve 60%, IAA+ve 74%, GADA+ve 86%

Effect of sirolimus versus mycophenolate mofetil on glucose metabolism in pancreas and kidney transplantation: final results of a prospective randomised study

T. Havrdova[1], F. Saudek[1], K. Lipar[2], T. Jedinakova[1], J. Skibova[3];
[1]Diabetes Center, [2]Transplant Center, [3]Statistical Department, Inst. Clinical Exp. Medicine, Prague, Czech Republic.

Objectives: Metabolic effects of immunosuppressive agents are important in pancreas or islet transplantation. The aim of our study was to compare glucose metabolism in Type 1 diabetic pancreas and kidney recipients on tacrolimus-based immunosuppression in conjunction with sirolimus (RAPA) or mycophenolate mofetil (MMF) in a prospective randomised study.
Methods: The investigation was performed in 40 insulin-independent rejection-free patients after simultaneous pancreas and kidney transplantation (with systemic venous drainage of pancreatic graft) on discharge from the hospital (0.60±3 [mean±SD] month post-transplant; with steroid dose 11±4.3 mg/day) and subsequently at 21.2±9.9 months (steroid-free). All recipients had a good function of the kidney graft. Fasting glycemia, insulin and C-peptide levels, HbA_{1c}, IVGTT with K_G-calculation were assessed in both groups. Insulin sensitivity was evaluated by HOMA-IR. Areas under the insulin/C-peptide curves during the IVGTT (AUC-IRI, AUC-CP) were used as the parameters of insulin/C-peptide secretion.
Results: The RAPA and MMF groups did not differ in age, BMI, post-transplant period and steroid daily dose. Trough levels of tacrolimus had no significant impact on any of examined parameters. K_G and HOMA-IR of the whole study group significantly improved between the exams (1.0±0.4 vs. 1.43±0.44 %/min., p<0.001 and 4.1±4.1 vs. 2.73±1.98, p<0.05, respectively). We found only a significant difference between the groups in stimulated AUC-CP after steroid withdrawal.

	RAPA group (n=20)		MMF group (n=20)	
	Examination 1 (a)	Examination 2 (b)	Examination 1 (c)	Examination 2 (d)
HbA1c (%)	6.3±0.9	5.6±0.5 (p<0.01 vs. a)	5.9±0.6	5.4±0.6 (p<0.05 vs. c)
Fasting glycemia (mmol/L)	5.2±0.6	4.8±0.5 (p<0.05 vs. a)	5.4±0.8	4.7±0.7 (p<0.01 vs. c)
K_G (%/min.)	1.0±0.5	1.35±0.36 (p<0.01 vs. a)	1.0±0.3	1.51±0.5 (p<0.001 vs. c)
AUC-IRI (mIU/L/60min.)	2056±1321	2062±1229	3148±2270 **(p<0.01 vs. a)**	2601±1368
AUC-CP (pmol/mL/60min.)	138.7±57.3	96,6±29.8 (p=0.001 vs. a)	180±85,1	114,7±33,7 (p<0.01 vs. c)
Stimulated AUC-CP (pmol/mL/60min.)	47.9±24.7	47.6±18.8	73.8±29 **(p<0.01 vs. a)**	63.8±22.6 **(p<0.05 vs. b)**
HOMA-IR	3.4±2.7	2.6±1.7	4.7±5.0	2.8±2.2

Conclusion: Glucose tolerance measured by IVGTT significantly improved in whole study group probably due to better insulin sensitivity after steroid withdrawal. The higher stimulated C-peptide secretion in the MMF was not associated with a significant difference in IVGTT results between the groups. In steroid-free tacrolimus based immunosuppression the choice of RAPA or MMF did not lead to clinically relevant differences in parameters of glucose metabolism.

Long-term (4 years) efficacy and safety of pancreas transplantation alone in type 1 diabetic patients

M. Occhipinti, U. Boggi, R. Giannarelli, A. Coppelli, R. Mariotti, A. Piaggesi, L. Rondinini, A. Tedeschi, M. Sartini, G. Amorese, M. Del Chiaro, C. Croce, F. Vistoli, P. Marchetti;
Dept. Endocrinology and Metabolism, University of Pisa, Italy.

Background and aims: The role of pancreas transplantion alone (PTA) in type 1 diabetic patients (T1DM) is still debated. This study describes the effects of pancreas transplant alone (single centre experience) on metabolic parameters, cardiovascular risk factors, diabetic complications and kidney function in type 1 diabetic patients followed up to 4 years post-transplant.
Materials and methods: We report our single centre experience on PTA in 71 T1DM (age: 38.4±8.5 yrs; gender: 37 males/34 females; body mass index, BMI: 23.5±3.0 kg/m^2; duration of diabetes: 23.7±9.9 yrs), with a follow-up of up to 4 yrs. Patients were transplanted according to the portal (73.2%) or systemic (26.8%) drainage technique, with enteric diversion of exocrine secretion. Immunosuppression consisted of induction with basiliximab (76.1%) or thymoglobulin (23.9%) and high-dose steroid, followed by mycophenolate mophetil, tacrolimus and low-dose steroid for maintenance.
Results: Patient and pancreas (insulin independence) survival at 4 yrs from transplant were respectively 98.4% and 76.7% with graft losses mainly due to immunological reasons. Relaparatomy was needed in 18.3% of cases, and 15.5% of recipients developed infections. Fasting plasma C-peptide levels rose from 0.15±0.33 ng/ml pre-transplant to 3.00±1.92, 2.78±1.40, 2.36±1.19 and 2.74±1.26 ng/ml at 1, 2, 3 and 4 yrs post-transplant. This was associated with sustained normalization of fasting plasma glucose concentrations and HbA1c levels. In addition, several cardiovascular risk factors (blood pressure, total and LDL-cholesterol and fibrinogen) decreased significantly after PTA and so remained up to 4 yrs of follow-up, with no apparent changes in anti-hypertensive or anti-dyslipidemic pharmacological treatment. Left ventricular ejection fraction, as assessed by ecography, rose from 54.4±4.3 to 57.4±3.2% (p<0.01) . PTA had also beneficial effects on diabetic retinopahy. Pre-transplant 7.5% patients had no retinopathy, and these remained lesion-free at 4-yrs-post operation. Of the 29.5% patients who had non-proliferative retinopathy, 75% improved and 25% remained unchanged, whereas in the gropu with proliferative and/ore laser treated retinopathy, the lesion were stable at 4 yrs post PTA in 82% of subjects and progressed to a more serious grade in the remaining 18%. Protenuria decreased from 1.36±2.72 to 0.29±0.51 g/24h (p<0.01) , which was associated with increased creatinine levels and reduced glomerular filtration rate; however, kidney function changes mainly depended on the pre-transplant status. Finally neuropathy assessment showed a significant improvement of several index of peripheral and autonomic responses after PTA.
Conclusion: We conclude that PTA was effective and reasonably safe in selected type 1 diabetic patients.

***In vivo* GSK3β knockdown hastens endocrine and exocrine pancreatic regeneration in 90 % pancreatectomised rats**

J. Movassat, F. Figeac, A. Ilias, M. Faro, B. Portha;
University Paris Diderot, Paris, France.

Background and aims: The Wnt signaling pathway has been recently implicated in pancreas development as well as in beta cell biology. Glycogen synthase kinase 3 β (GSK3β), a pivotal partner of the Wnt signaling is a multifunctional enzyme that negatively regulates the growth and function of the beta cells. The aim of our study was to assess the impact of GSK3β downregulation on the stimulation of exocrine and endocrine regeneration after subtotal pancreatectomy in rat.
Materials and methods: Adult Wistar rats underwent 90% pancreatectomy. In groups of pancreatectomized rats, either antisense oligonucleotides directed against GSK3β (AS-GSK3β) or LiCl were injected directly within the remnant pancreatic tissue immediately after pancreatectomy. Two additional groups were administered with non specific standard oligonucleotides (Std group) or with saline and were used as control for the AS-GSK3β and LiCl treated groups respectively. Beta cell mass was assessed by morphometry 7 days and 4 weeks after pancreatectomy. Beta cell, ductal cells and acinar cell proliferation was measured by BrdU incorporation method 8h and 48h after surgery. Apoptosis was assessed in beta cells, ductal cells and acinar cells by the TUNEL method
Results: GSK3β down regulation via administration of LiCl or AS-GSK3β greatly improved the beta cell regeneration 7 days after surgery (p<0.01). Moreover the use of AS-GSK3β had sustained effect on the beta cell mass, since 4 weeks after surgery the beta cell mass in the remnant pancreas was found to be higher (p<0.05) in AS-GSK3β treated group compared to the Std treated group. The effect of GSK3β inactivation on the beta cell mass seemed to be mediated by the stimulation of beta cell proliferation. Regarding the exocrine pancreas, GSK3β knockdown significantly stimulated acinar cell proliferation. Interestingly, GSK3β inactivation reduced the number of apoptotic acinar cells compared to that found in the control Std group.
Conclusion: Here we show that intra pancreatic knockdown of GSK3β in vivo, promotes both endocrine and exocrine regeneration within the remnant pancreas and could have potential application in the treatment of diabetes and other pancreatic diseases such as pancreatitis.

Effects of gastrin-treatment on pancreatic metaplasia in pancreatectomised rats

N. Tellez[1,2], M. Vilaseca[1], E. Montanya[1,2];
[1]Lab. Diabetes and Experimental Endocrinology, IDIBELL-University of Barcelona, L'Hospitalet de Llobregat, [2]CIBERDEM, Barcelona, Spain.

Background and aim: We have recently found that gastrin treatment improved glucose tolerance and increased beta cell regeneration in pancreatectomized rats. Gastrin stimulated the expression of the crucial transcription factors *ngn3*, *neuroD1*, *pdx-1* and *nkx6.1*, required for beta cell differentiation, in the early phase of regeneration after pancreatectomy (Px). In these initial days pancreatic tissue undergoes remodeling with increased proliferation in the ductal epithelium. The mitogenic activity of the epithelial ductal cells is first seen in the common pancreatic duct and later on in smaller ducts and in metaplastic tissue with tubular complexes (TC), previously identified as "focal areas of regeneration". These regions of regeneration are composed of tubular structures surrounded by mesenchymal cells with high proliferative rate. The aim of this study was to investigate the effects of gastrin on the phenotype of these focal areas of regeneration.
Material and Methods: Sprague-Dawley rats underwent 90%-Px and were treated with [15leu] gastrin-17 (Px+G, n=19) or with vehicle (Px+V; n=20). Pancreatic remnants were harvested on days 1 and 3 after Px and processed for total RNA extraction or paraffin embedding. Gene expression was determined by quantitative real time PCR and protein identification by immunofluorescence.
Results: 3 days after Px, beta cell relative volume was higher in the pancreatic remnants of gastrin-treated rats than in vehicle-treated group (Px+G: 0,57±0,10% vs Px+V: 0,26±0,07%, p=0.03). Beta cell proliferation was similar

in Px+G (2.99±0.32%) and Px+V (3.98±0.35%, *p NS*) groups, suggesting that the higher beta cell relative volume in Px+G group was not due to increased beta cell proliferation. Twenty-four hours after Px, the areas of regeneration accounted for 6.81±1.11% and 5.95±2.16% of the total pancreatic tissue in Px+V and Px+G groups respectively. On day 3, the areas of regeneration had expanded to 38±7.05% and 35.1±5.68% of the total pancreatic tissue (Px+V and Px+G respectively). Two types of TC were identified, TC consisting of many small duct-like cells with strong immunoreactivity for CK20 antibody, and TC formed by few larger cells which exhibit lower levels of immunofluorescence for CK20. TC with small duct-like cells were predominant in Px+V rats, whereas TC with larger cells were more frequent in the gastrin-treated group. Concordantly, gene expression of ductal cell markers (*ck20*, *ca2*, *hnf1β*, *hnf6*) was higher in pancreatic remnants of Px+V rats than Px+G group ($p<0.05$).

Summary and Conclusion: Pancreatic remnants of gastrin-treated rats showed increased beta cell relative volume but similar beta cell proliferation than vehicle-treated rats. In pancreatic remnants from Px+G group, gene expression of ductal cell markers was lower than in Px+V group, and the focal areas of regeneration showed TCs with predominantly larger cells with weak CK20 immunofluorescence. These results suggest that gastrin-induced beta cell regeneration after pancreatectomy may involve phenotypic changes in the metaplastic tissue. Further analysis of these areas of regeneration will provide valuable information to understand the mechanisms of gastrin-induced beta cell regeneration.

MafA promotes maturation of mouse embryonic progenitor-derived insulin-producing cells

Y. Gao[1], S. Shao[1], B. Xie[1], W. Nishimura[2], A. Sharma[2], G. Li[1];
[1]National University Medical Institutes, National University of Singapore, [2]Joslin Diabetes Center, Harvard Medical School, Boston, USA.

Background and aims: Shortage of cadervic pancreata has restricted the transplantation therapy of curing insulin-dependent type 1 diabetes. Generation of functional insulin-producing cells from stem cells may circumvent this obstacle. We established a dozen of expansible and glucose-responsive insulin-producing cell lines (e.g. MEPI and ERoSHK) from differentiation of mouse embryonic stem and progenitor cells. Transplantation of these cells in diabetic animals could correct hyperglycemia, but they also revealed features of immaturation as reflected by higher un-regulated insulin release and slow continuous proliferation in vivo. Consistent with the role of MafA (v-maf musculoaponeurotic fibrosarcoma oncogene homolog A) as a master transcription factor implicated in regulating islet β-cell development and glucose responsiveness, its expression was significantly lower in our insulin-producing cells. This study tests the hypothesis that the restoration of MafA levels will improve the function of progenitor-derived insulin-producing cells.

Materials and methods: Mouse embryonic progenitor-derived insulin-producing (MEPI)-1 cells were transfected with lentivirus expressing MafA, followed by assessments of various cell functions. MafA was determined by real time RT-PCR, immunofluorescence staining and immunoblotting.

Results: MafA levels in MEPI-1 cells could be restored to that present in isolated adult islets after 72-h transfection with the virus. Insulin expression and its content were enhanced by about 20% whereas the cell proliferation rate was reduced after restoration of MafA. MafA overexpression significantly enhanced expression of several molecules important for β-cell functions, including glucagon-like peptide-1 (GLP-1) receptor, Glut2, glucokinase, Nkx6.1 and Kir6.2 in MEPI-1 cells. These cells exhibited better signaling responses to glucose stimulation, i.e. higher glucose metabolic rate and ATP generation, enhanced membrane potential depolarization and larger rise of intracellular Ca^{2+} concentrations. Notably, restoration of MafA markedly improved glucose-stimulated insulin secretion (GSIS) profile, revealing a suppressed basal insulin release and shifting the dose-response curve of insulin secretion upon glucose stimulation similarly to that observed in isolated islets. In addition, insulin secretion induced by high K^+, glibenclamide and GLP-1 was also augmented.

Conclusion: Our data demonstrate that normalization of MafA levels in MEPI-1 cells enhances expression of the β-cell relevant gene profile, reduces cell proliferation, elevates insulin biosynthesis and substantially improves GSIS via augmenting multiple signaling cascades. Therefore, we suggest that MafA can promote maturation of embryonic stem cell-derived insulin-producing cells, making them suitable for cell replacement therapy of type 1 diabetes.

Role of Maf transcription factors in the endocrine cell differentiation in the developing pancreas

M.A. Mazur, I. Artner;
Stem Cell and Pancreas Developmental Biology, Lund University, Lund, Sweden.

Background and aims: Pancreatic endocrine cell differentiation is dependent on the interactions of several transcription factors. MafA and MafB are essential activators of insulin and glucagon expression. However, MafA and MafB are distinct from others in regards to temporal and islet cell expression pattern, with beta cells only affected by MafB during development and exclusively by MafA in the adult. To elucidate the function of MafA and MafB in β cell differentiation, E18.5 mutant pancreata were analyzed for changes in gene expression. From these gene profiling studies several genes regulated by MafA and MafB factors were identified.

Materials and methods: To identify genes regulated by MafB, expression profiling was performed on wild type and MafB-/- pancreata at embryonic day 18.5. Samples of embryonic and adult tissue were evaluated for candidate genes by qRT-PCR, immunohistochemistry and in situ hybridization.

Results: The microarray studies showed that expression levels of several genes are altered in MafB deficient mice. Gene ontology analysis revealed that the differentially expressed genes were mainly associated with mature beta cell function, such as ion binding and transport, signal transduction, and hormone secretion. This suggests that MafB is involved in beta cell maturation and function. My experiments have shown that Neuronatin (Nnat) and islet-specific zinc transporter (Slc30a8), Endothelin receptor B (Ednrb), Melanocortin 3 receptor (Mc3R), and Microphthalmia associated transcription factor (Mitf) are downregulated in mutant embryonic pancreata. In contrast, the mRNA level of Retinol Binding Protein-4 (Rbp4) was upregulated in mutant tissue. Immunohistochemical analysis shows that Mitf, Ednrb and Mc3r are expressed in the adult pancreas. Endothelin and melanocortin signalling pathways are coupled in the modulation and expression of Mitf gene.

Conclusion: These novel findings indicate a possible involvement of Mitf, Ednrb and Mc3r in the differentiation of pancreatic endocrine cells and adult beta cell function.

Glucagon-like peptide 1 protein and receptor are present during embryonic life. Biological effects and gene targets

C. Sanz[1], P. Vázquez[1,2], E. Blázquez[1];
[1]CIBERDEM-University Complutense of Madrid, [2]Centro de Investigaciones Biológicas (CSIC), Madrid, Spain.

Background and aims: Glucagon-like peptide 1 (GLP-1) functions during adult life as an incretin hormone with antidiabetogenic properties. However, the role of GLP-1 if any, in early stages of development or in undifferentiated cells, such as human bone marrow mesenchymal stem cells (hMSCs) or mouse embryonic stem cells (mES), remains unknown and it was the aim of this study.

Materials and methods: The presence of GLP-1 and GLP-1 receptor were tested by immunostain of mES and hMSC, as well as in mouse embryos (E 8.5, E10.5 and E13.5). Furthermore, the effects of GLP-1 were tested in hMSC under proliferative, cytoprotective and adipogenic conditions and signalling pathways involved in these processes were also analyzed. Additionally, GLP-1 genes target were studied by quantitative gene expression in a TaqMan Low Density Array.

Results: The isolated hMSCs expressed mRNA and GLP-1 receptor protein. One-day treatment with 10 nM GLP-1 did not modify the stem cell markers SCF, nestin, c-kit and Thy-1, but produced a transcriptional induction of the pancreatic transcription factors neurogenin-3, isl-1 and ipf-1. GLP-1 increased the proliferation of hMSCs, which decreased when they were induced to differentiate into adipocytes. Differentiation produced biochemical and cell morphologic changes with the expression of PPARγ, c/EBPβ, AP2 and LPL in a time-dependent pattern. Interestingly, GLP-1 significantly reduced the expression of PPARγ, c/EBPβ and LPL (inhibition of 30%±4, 33%±2 and 90%±5 respectively). These effects were, at least, exerted through MEK and PKC signalling pathways. In addition, GLP-1 significantly reduced cell apoptosis. In other way, both, peptide and GLP-1receptor were present in mouse embryonic stem cells derived from the inner cell mass where were

found new genes target for GLP-1. Likewise, they were mainly present in cells derived from ectodermal and endodermal linages, in early development of the mouse.
Conclusion: Our data indicate that GLP-1 promotes proliferation and cytoprotection of hMSC, at the same time as it prevents its differentiation into adipocytes, which suggests that this peptide may play a role in the renewal of tissues. Furthermore, both peptide and receptor are present in embryonic life before GLP-1 may play a role as an incretin and modulates the expression of new target genes in mouse embryonic stem cells. These results open new views about the role of this peptide during different periods of life.

Ablation of FGFR2b in a subset of pdx1+ pancreatic progenitor cells
Z.M. Löf-Öhlin, P. Nyeng, I. Artner, H. Semb;
Stem Cell & Pancreas Developmental Biology, Lund University, Lund, Sweden.

Background and aims: Mesenchymal-epithelial interactions mediated by Fibroblast growth factor receptor 2b, FGFR2b, and its ligand FGF10 have been shown to play an important role in early pancreatic development by regulating proliferation and differentiation. However, it is not know if these effects are direct or indirect due to interactions between the pancreatic epithelium and mesenchyme.
Materials and methods: To address the functional role of FGFR2b in pancreatic development in a cell-autonomous fashion, we generated mice with a conditional mosaic deletion of *FGFR2b* under regulation of the *pdx1* promoter. All statistical analyses were performed using GraphPad Prism version 4.03 and t-tests.
Results: This study confirms that *FGFR2b* deletion in a subset of pancreatic progenitors results in a smaller pancreas due to reduced proliferation of pdx1+ cells. We have also successfully narrowed this lack of proliferation down to between embryonic day e13.5 and e14.5. Surprisingly, the cells still retained their ability to differentiate into all lineages of the pancreas, although the ductal development was favored at the expense of the exocrine.
Conclusion: We conclude that proliferation mediated by FGFR2b is cell autonomous while differentiation defects are rescued in the mosaic mouse model, suggesting that there is signaling crosstalk between mutant and wild type cells. Which these secondary signals are and how the differentiated cells behave in terms of migration capacity, maturation status and functionality are still to be determined.

Gene therapy of diabetic rats by hepatic insulin expression after lentiviral gene transfer
M. Elsner[1], T. Terbish[1], A. Jörns[2], S. Lenzen[1];
[1]Institute of Clinical Biochemistry, [2]Center of Anatomy, Hannover Medical School, Germany.

Background and aims: The release of insulin from non-endocrine cells is an interesting therapeutic concept for the treatment of insulin dependent diabetes mellitus. Modern lentiviral vector systems are able to transduce non-dividing cells and are therefore a valuable tool for gene therapy approaches. The aim of the present study was to normalise the blood glucose concentrations by lentiviral gene transfer of the human insulin gene into hepatocytes of diabetic rats.
Materials and methods: The cDNA of furin-cleavable human insulin was subcloned into a lentiviral vector system. The ubiquitous protease furin allows a processing of proinsulin into mature biological-active insulin in non-endocrine cells. Lentiviruses were isolated by ultrafiltration with a titer of $7x10^9$ infectious particles per ml. Virus solutions were injected into the portal vein of immune-diabetic IDDM and STZ-diabetic rats. Diabetic controls were treated with GFP lentivirus. The blood glucose concentrations and the body weight of the treated animals were measured over one year. 30 and 270 days after virus injection oral glucose tolerance test (OGTT; 2 g/kg body weight) were performed. The serum insulin and c-peptide concentrations were measured by an EILSA. The insulin expression in the liver and the pancreas was analysed by PCR and immunostaining.
Results: 10 days after injection of insulin lentivirus into the portal vein of immune-diabetic IDDM or STZ-diabetic rats the blood glucose concentrations were lowered from 21.6 mmol/l ± 4.6 to 5.9 mmol/l ± 1.1 or from 19.6 mmol/l ± 3.5 to 5.5 mmol/l ± 0.7, respectively. In control rats treated with GFP virus was no significant reduction of the blood glucose concentration detectable. The blood glucose concentration after OGTT of rats injected with insulin virus increased up to 19.7 mmol/l after 30 min and were normalised after 3 h. The serum insulin concentrations increased from <0.1 ng/ml to 2.1 ng/ml after treatment with insulin lentivirus. The rat c-peptide concentrations were below the detection limit. Insulin expression in the liver was detected by PCR and immunostaining. Around 20 % of the hepatocytes were insulin positive. The hepatocytes showed no signs of transdifferentiation into beta cells.
Conclusion: The lentiviral gene transfer of furin-cleavable human insulin into hepatocytes of immune-diabetic IDDM and STZ-diabetic rats leads to a blood glucose normalisation for more than one year. The insulin was processed in the hepatocytes and released constitutively from the cells. This study shows that the diabetic state can be improved by insulin release from non-endocrine cells in a somatic gene therapy approach.

Background and aims: Pancreatic beta cell mass undergoes major remodeling during neonatal growth and adult life. It has been established that both in Type 1 and Type 2 diabetes there is a significant loss of insulin-producing beta cells and consequently decreased functional beta cell mass. The molecular mechanisms that regulates beta cell mass are still not fully characterized. Since Hedgehog (Hh) pathway plays an important role both in endocrine pancreas development and in the regulation of insulin secretion, we have focused our attention on the contribution of Hh pathway in the regulation of beta cell mass after beta cell injury. To this end, we have studied the expression of Hh signaling key molecules (transcription factors Gli1, Gli2, Gli3) and of Hh receptor Ptch, in C57/BL6 mice in which diabetes was induced by streptozotocin (STZ).
Materials and methods: Six-week old C57/BL6 male mice (n=12) were intraperitoneally injected with a single dose of STZ (200mg/kg b.w.) and then sacrificed and pancreas was collected after 1, 3, 7 and 10 days post STZ administration. In addition, a group of 6-week old C57/BL6 male mice (n=10) not treated with STZ was used as control. The expression of Gli-1, -2, -3, and of the inhibitory receptor Ptch was analyzed on pancreatic sections by indirect immunofluorescence with confocal microscopy analysis. In order to establish the endocrine cell type expressing the Hh molecules of interest, double immunostaining for each of the Hh component and for insulin, glucagon and somatostatin was performed as well.
Results: In untreated mice, Gli1 was expressed both in alpha and beta cells, while Gli2 and Gli3 expression was beta-cell specific. Following STZ administration, Gli1 was not detected in the residual beta cells (1 and 3 days post-STZ) in which it reappeared after 7 days; Gli1 expression remained unchanged in alpha cells after STZ. In contrast, expression of Gli2 and Gli3 did not change in beta cells. Of note, Gli2 and Gli3, which showed a beta-cell specific expression in untreated mice, were detected in alpha cells in a time window between 1 and 3 days post STZ. As for the inhibitory receptor Ptch, this was detected only in somatostatin-positive cells (i.e. delta cells) and its expression was not affected by STZ treatment.
Conclusion: These data show a differential expression, among pancreatic endocrine cell subsets, of Gli transcription factors family members and that such expression is modulated in response to beta cell injury, thus confirming the involvement of Hh pathway in the regulation of beta cell mass. Moreover, the expression of the inhibitory receptor Ptch only in delta cells indicates that in these cells the Hh pathway is inactive and indirectly supports the hypothesis that Hedgehog signaling is indeed involved in the development and regulation of both alpha and beta cells.

Adaptive response of pancreatic alpha cells and hepatic carbohydrate metabolism during chronic nutritional deprivation

E. Fernández-Millán[1], J. De Toro-Martín[2], E. Lizárraga-Mollinedo[1], F. Escrivá[1,2], C. Álvarez[1,2];
[1]Ciber de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM). ISCIII, [2]Bioquímica y Biología Molecular II, Facultad de Farmacia Universidad Complutense, Madrid, Spain.

Background and aims: Type 2 diabetes is mainly characterized by β-cell secretory dysfunction and decreased β-cell mass but inappropriate levels of circulating glucagon and increase in the α-cell/β-cell mass ratio are also important determinants of the hyperglycemia seen in type 2 diabetes patients. In rats, pancreatic β-cell development is particularly sensitive to an altered intrauterine environment what contributes to increase the incidence of adult onset type 2 diabetes. However, little is known about the contribution of α-cells in this context. We previously showed that food-restriction applied during the last third of gestation caused in fetuses at term, an increase of β-cell mass, hyperinsulinemia and enhanced insulin secretion while prolonged malnutrition until adulthood impaired β-cell growth and functionality. Therefore, our first aim was to determine whether maternal food-restriction would affect α-cell growth and functionality in offspring. Since pancreatic hormones play a crucial role in the regulation of hepatic glucose metabolism, our second aim was to examine the adaptive changes of carbohydrate metabolism in response to chronic food deprivation.
Materials and methods: Wistar rats were 65% food-restricted from the last week of gestation until adult age. The experiments were carried out in fetuses at term, in suckling and adult rats. α-cell mass, neogenesis and apoptosis were evaluated by immunocytochemistry and morphometry. For the study of α-cell function fetal and adult islets were isolated. Serum hormone levels, islet glucagon secretion and content were measured by radioimmunoassay. Basal glycogen storage, PEPCK activity and phospho- and total GSK3β protein levels were determined in homogenized livers after fasting.
Results: Undernourished (U) suckling rats were hypoglycaemic. Serum insulin/glucagon ratio was higher in U fetuses and neonates on postnatal day 4 (PN4) as compared to controls (C) but, from PN14 onwards this ratio was lower in U rats. Moreover, glucagon secretion was damaged in U fetuses and adults. α-cell mass increased from fetal period to PN14 then, it remained stable until PN23 and finally, it decreased at adult age in both populations. However, U rats showed defective α-cell mass comparing with C at all the ages studied. The impaired α-cell growth was neither due to increased α-cell apoptosis nor decreased neogenesis but to the presence of islets of smaller size. Liver glycogen content was enhanced in U rats at all the ages studied and this was associated with a higher inhibition of GSK3β. In contrast, PEPCK activity was found impaired from PN14 to adulthood in U rats.
Conclusion: 1) Intra-uterine growth restriction due to maternal malnutrition induces a defective metabolic adaptation of neonates to extrauterine life; 2) The factors involved include morphological and functional alterations of pancreatic α- and β-cells, improved efficiency to store glycogen in the liver but impaired glyconeogenesis; 3) This adaptive process could be crucial to survival during periods of nutritional scarce but detrimental in case of normal diet or overfeeding.

Live *in vivo* imaging of Langerhans islets in normal and diabetic mice by extended focus optical coherence microscopy

J. Goulley[1], M. Villiger[2], C. Berclaz[1], P. Meda[3], A. Grapin-Botton[1], T. Lasser[1];
[1]UPGRA, EPFL-SV, Lausanne, [2]LOB, EPFL, Lausanne, [3]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: Structural and functional imaging of the islets of Langerhans and the insulin-secreting beta cells during diabetes progression represents a significant challenge and a long lasting objective. We have developed extended focus optical coherence microscopy (xfOCM) to image murine islets of Langerhans *in- vivo*. No labeling is required, since the native, intrinsic scattering properties of pancreatic tissues allow for a direct visualization of endocrine islets of various sizes, blood vessels and ductal tree. Moreover, streptozotocin-induced destruction of beta-cells was detected and quantification of this depletion was determined *in-vitro* to evaluate the sensitivity of xfOCM. A longitudinal study performed on NOD mice, a model of type I diabetes, unraveled new perspectives for xfOCM to image onset and progression of diabetes.
Materials and methods: A very same group of NOD mice was repeatedly monitored using xfOCM prior to the development of diabetes, at the early onset of the disease, weeks later and just before sacrifice. Imaging was followed by automated quantification of islet mass. The same animals were regularly sampled for basal glucose measurement tests, intraperitoneal glucose tolerance tests, and body weight measurements. Histological analysis of the pancreata after immunohistochemistry allowed us to characterize the nature of the detected structures.
Results: We show that xfOCM can detect islets of Langerhans in the absence of labeling in mice, and that the islet mass in the sample can be quantified. The longitudinal in vivo imaging study performed on NOD mice shows that (1) we can detect infiltrated islets (2) a decrease in beta cell mass measured by xfOCM is detected prior to detection of impaired glucose tolerance and overt diabetes. The presence of infiltrated islets and beta cell mass disappearance were confirmed by immunohistochemistry.
Conclusion: Our results demonstrate that xfOCM is a suitable tool to assess insulitis and beta cell mass loss prior to impaired glucose homeostasis and diabetes. Therefore, xfOCM will be useful to anticipate a diabetes outcome, since it non-invasively captures islet alterations that cannot be appreciated in vivo by other methods.

Bioluminescence quantifies alterations of beta cells mass in living Ins-DTR mice

L. Vinet[1], J. Virotsko[2], D. Caille[1], O. Fazio[1], A. Powers[2], P.L. Herrera[1], P. Meda[1];
[1]Université de Genève, Switzerland, [2]Vanderbilt University, Nashville, USA.

Background and aims: Studies of β cell loss in the pre-diabetic and diabetic state are impeded by the inability to non-invasively assess pancreatic β cell mass. Non-invasive imaging may also aid the development of therapeutic interventions aimed at mitigating the diabetes-related β cell loss or to regenerating islets. Current methods for quantifying β cell mass and regeneration require the sacrifice of mice and the analysis of pancreatic sections, and do not allow for a sequential evaluation of β cell loss and regeneration in individual mice over time. To assess whether bioluminescence may help to address this problem, we generated MIP-Luc/Ins-DTR double transgenic mice which express the diphtheria toxin receptor (DTR) and luciferase (Luc) under the control of the insulin promoter, i.e. specifically in β cells. In these mice, injection of luciferin permits the emission of photons from β cells, whereas injection of diphtheria toxin (DT) causes a loss of the cells expressing DTR.
Materials and methods: Two-3 month old MIP-Luc/Ins-DTR double transgenic mice, both on a C57BL/6 genetic background, were injected 3 times i.p. with DT at 3 day intervals. When blood glucose was > 450 mg/dl, mice received a s.c. insulin implant. At weekly intervals, bioluminescence imaging (BLI) was recorded from a pancreatic region of interest, 5, 10, 15 and 25 min after the luciferin injection.
Results: In control MIP-Luc mice, the BLI recorded over the pancreas remained stable for the 4 month duration of the experiment. Prior to DT injection, males and females MIP-Luc/Ins-DTR mice had similar values of BLI.

After DT injection, this BLI signal sharply decreased in males (n=5) to about 5-10% its initial value, as the animals developed hyperglycaemia, consistent with a major loss of β-cells. BLI, then, remained at this low level throughout the rest of the experiment. In age-matched females (n=4), DT decreased pancreas BLI by 40-70%, but did not cause hyperglycemia, consistent with the loss of only a fraction of the β-cells. The BLI, then, remained stable for the first 2 months. Thereafter, it increased, suggesting a change in β-cell mass and/or in the efficiency of the photon emission. In this model, the BLI and blood glucose changes differed in males and females, due to the targeted insertion of the DTR transgene to the X chromosome.
Conclusion: The data show that bioluminescence provides for a non-invasive monitoring of graded, and sequential changes in β-cells mass within individual mice.

Islets transplanted into the anterior chamber of the eye serve as a mirror of *in situ* pancreatic islets

E. Ilegems[1], A. Bahow[1], A. Sharma[1], A. Dicker[1], S. Speier[2], P. Karlsson Edlund[1], M. Köhler[1], I.B. Leibiger[1], P.-O. Berggren[1];
[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Technical University Dresden, Germany.

Background and aims: Since insulin-secreting beta-cells are located in the endocrine pancreas, deeply embedded in the exocrine pancreas, imaging of beta-cells in living organisms is difficult. The anterior chamber of the eye was recently proposed as a transplantation site for non-invasive *in vivo* imaging of pancreatic islets. This location can be used as a natural "body-window" allowing for a repetitive assessment of islet mass and function. The aim of the present study is to demonstrate that islets transplanted into the anterior chamber of the eye are representative of the islets status in the endogenous pancreas.
Materials and methods: We performed syngeneic transplantations into control and obese-hyperglycemic ob/ob mice - a model for type 2 diabetes. Animals were transplanted into the anterior chamber of the eye at 4 weeks of age with islets isolated from age-matched donors. Pancreas and transplanted eyes were collected 3 months later and processed for immunohistochemical studies.
Results: Immunohistochemical staining for insulin showed an altered expression pattern in both ob/ob pancreatic and transplanted islets as compared to control mice. Islets in ob/ob mice showed a strong proliferation rate (1.0 ± 0.2 %) as well as an increased size of beta cells (+30 %), both at the transplantation site and in the endogenous pancreas. The typical increase in intra-islet vessel diameter in the ob/ob mouse was also observed and found to be identical in transplanted islets. We next aimed at demonstrating islet plasticity in the anterior chamber of the eye. Ob/ob mice were treated with daily injections of leptin 2 months after transplantation. After 1 month of treatment, their blood glucose levels normalized and their body weight diminished to reach a similar value as in control mice. Immunostaining at this time point showed that the typical islet properties of ob/ob mice were reversed: quantification of beta cell size, proliferation, and vessel diameters gave similar values as observed in control non-obese mice.
Conclusion: Islets transplanted into the anterior chamber of the eye reflect endogenous pancreatic islets properties. This transplantation site thus serves as a perfect imaging platform allowing for a non-invasive and repetitive assessment of islet function and beta-cell mass regulation at single-cell resolution under normal and diabetic conditions.

High resolution magnetic resonance imaging detects individual pancreatic islets in whole pancreas

S. Lamprianou[1], R. Immonen[2], A. Gjinovci[1], L. Vinet[1], R. Gruetter[2], P. Meda[1];
[1]PHYME, Université de Genève, [2]Laboratory for Functional and Metabolic Imaging, EPFL, Lausanne, Switzerland.

Background and aims: In type 1 and type 2 diabetes the gradual loss of pancreatic β-cell function and mass leads to impaired regulation of blood glucose with severe secondary peripheral effects. Currently, we lack non invasive methods for monitoring the evolution of the disease. β-cells make-up 80% of the islets of Langerhans which, in the adult, represent 1% of the total pancreatic volume, have a diameter of 30-600 μm and are scattered within the pancreas. Imaging these islets in vivo is the ultimate challenge. To approach this goal, we tested whether the ultra high field of 14.1T MRI, in combination with manganese infusion, can image individual pancreatic islets.
Materials and methods: Mice were untreated (3 mice) or subjected to a MnCl2 i.v. infusion together with a glucose i.p. stimulus (6 mice). MnCl2 and glucose infused mice were further injected i.p. with either streptozotocin (STZ) (4 mice) or citrate buffer (5 mice). In all cases, the pancreata were excised, fixed in 4% PFA for 6h and placed into Fomblin. Samples were then imaged in a 14.1T 26 cm horizontal bore scanner using quadrature half-volume coil 20 mm in diameter. High resolution images were acquired using gradient echo multi slice sequence with fourteen 0.3 mm-thick slices, FOV 26*25 mm, data matrix 512*512 (51*49 μm in plane resolution) to cover the whole mouse pancreas. Two sets of combined T1 and T2* weighted images (TR=282 ms, TE=7 ms, flip=60°, 30 averages and TR=500 ms, TE=14 ms, flip 60°, 20 averages) were acquired for optimal tissue contrast.
Results: The ultra high field of 14.1 T allows for the visualization of different pancreas tissues (lymphatic ganglia, ducts and vessels), whose identity was ascertained by histology. Structures that featured the size, shape and distribution of pancreatic islets were also revealed. The MRI signal of the later structures was enhanced by MnCl2 and glucose infusion, and their islet nature was demonstrated by histological analysis. The distribution of islet areas observed in MRI images was consistent with that evaluated in the histological sections of the very same samples. However, the two distributions were not identical, due to the shrinking of the pancreas during the histological treatment, and to the partial volume effects ascribed to the finite slice thickness of MRI. Preliminary experiments indicate that the approach can detect the loss of islets induced by injection of a diabetogenic dosis of STZ.
Conclusion: We conclude that, when using high resolution MRI together with manganese and glucose infusion, individual pancreatic islets can be visualized within the whole pancreas in the absence of β-cells targeted labeling. The study provides the first proof of concept that a clinically relevant imaging method could be applied for visualizing individual islets in vivo and holds promise for the evaluation of the β-cell changes induced in diabetes.

Vesicular monoamine transporter 2 gene expression in beta cells of primates but not of rodents: implications for developing radioligands for imaging of beta cell mass in animal models

M.K. Schafer[1], L.E. Eiden[2], E. Weihe[1];
[1]Molecular Neuroscience, Institute of Anatomy and Cell Biology, University of Marburg, Germany, [2]Section on Molecular Neuroscience, NIMH, Bethesda, USA.

Background and aims: Imaging of pancreatic islets and in particular of beta cell mass is a major challenge in diabetes research. Our original observation that the vesicular monoamine transporter 2 (VMAT2) is expressed in the vast majority of human and non-human primate beta cells has led to the suggestion that VMAT2 is a promising biomarker of beta cell mass independent of mechanisms of insulin production. Consequently, radiolabeled analogs of tetrabenazine, a low molecular weight VMAT2 selective ligand, have been employed for pancreatic islet imaging in humans and rats. However, controversial results and limited success in discrimination from background and avoiding overestimation of beta cell mass were obtained. Here we investigated VMAT2 expression patterns in mouse and rat pancreas in order to determine whether these rodents qualify as suitable models to optimize tetrabenazine based beta cell mass imaging.
Materials and methods: Pancreatic tissue was obtained from Wistar, Sprague Dawley and Lewis rats as well as from C57/BL.6 and Balb-C mice. Deparaffinized sections or cryosections from formaldehyde or Bouin Hollande fixed tissues were processed for immunocytochemistry with a panel of species-specific VMAT2 antisera and in situ hybridization in combination with immunostaining for insulin and RT-PCR analysis from laser-microdissected beta cells.
Results: We demonstrated lack of specific VMAT2 expression in beta cells of both mice and rats throughout development. Our antisera revealed an abundant network of VMAT2 positive catecholaminergic innervation costained for tyrosine hydroxylase, the rate limiting enzyme of catecholamine biosynthesis. Absence of VMAT2 transcripts from beta cells was confirmed by RT-PCR analysis from laser-micodissected beta cells. In contrast, beta cells from primates exhibited abundant VMAT2 expression on the mRNA and protein level as previously reported. Thus, it is clearly shown that primate but not rodent species qualify as animal models for beta cell mass imaging with radiolabeled VMAT2 ligands such as 11-C-dihydrotetrabenazine or newly developed VMAT2 biomarkers.

Conclusion: The choice of species is crucial for developing optimal animal models for beta cell mass imaging and requires proof of principle experiments including species-specific gene expression analysis that the biomarker in question is truly valid for both humans and the animal model used. Tetrabenazine remains one of the ligands of choice for imaging of VMAT2 in human pancreas, however existing animal models must be adjusted and/or chosen carefully. Transgenic VMAT2 mice under the insulin promoter may be a way to provide a rodent model for pancreatic beta cell imaging.

In vivo visualisation of transplanted islets in rat by SPECT imaging with ^{111}In-Exendin-3

K.M. Andralojc, M. Brom, L. Joosten, W. Oyen, O. Boerman, M. Gotthardt; Department of Nuclear Medicine, Radboud University Nijmegen Medical Center, Netherlands.

Background and aims: At this moment, there is no reliable non-invasive method to determine beta-cell mass *in vivo*. Such a method would not only allow longitudinal studies on the engrafted islets survival in case of human islet transplantation, but might also enable improved treatment of patients with immune-suppressive drugs to prevent rejection of transplanted islets. We have developed a non-invasive imaging technique that specifically visualizes beta-cells *in vivo*. This method is based on the targeting of the glucagon-like peptide 1 receptor (GLP-1R). The GLP-1R is expressed at high levels on pancreatic beta-cells. We have developed an In-111-labeled tracer that specifically binds to the GLP-1R: In-111-labeled Exendin-3. Previous studies showed a linear correlation between the beta-cell mass and Exendin-3 uptake. We examined whether intramuscularly transplanted beta-cells in rats could be visualized by SPECT (Single Photon Emission Computed Tomography) imaging after i.v. injection with radiolabeled Exendin-3.
Materials and methods: Langerhans islets were isolated from Wag/Rij rats and cultured overnight in RPMI medium prior to transplantation. One thousand islets were transplanted in the left hind limb muscle of Wag/Rij rats, while vehicle was injected in the right muscle as a control (n=3). Two, 7 and 14 days after transplantation ^{111}In-labeled Exendin-3 was injected intravenously and SPECT images were acquired 1 hour post injection using a U-SPECT II microSPECT scanner. After acquiring the SPECT images at the day 14 the rats were euthanized and the radioactivity in the transplant and other relevant tissues was measured. The muscle with engrafted islets was fixed and embedded in paraffin for autoradiography and immunohistochemical analysis.
Results: The transplanted islets were clearly visualized with SPECT at 7 and 14 days after transplantation. *Ex vivo* autoradiography of the engrafted islets showed high uptake of In-111-Exendin-3 in the islets. Immunohistochemistry confirmed that those islets were viable and produced insulin. In-111-Exendin-3 uptake in the muscle with the engrafted islets was higher than uptake in the control muscle (0.27±0.06 %ID vs 0.07±0.02 %ID).
Conclusion: ^{111}In-Exendin-3 accumulated efficiently in transplanted islets. Transplanted islets could be clearly delineated by microSPECT imaging after injection of ^{111}In-Exendin-3. ^{111}In-Exendin-3 could potentially be used for non-invasive beta-cell mass determination of transplanted islets.

Quantitative determination of the beta cell mass by SPECT imaging with ^{111}In-DTPA-Exendin-3 in rats

M. Brom[1], P. Baumeister[2], S. Verwijnen[3], L. Joosten[1], P. Laverman[1], M. Béhé[4], M. de Jong[3], W. Oyen[1], O. Boerman[1], M. Gotthardt[1];
[1]Department of Nuclear Medicine, Radboud University Nijmegen Medical Centre, Netherlands, [2]Department of Nuclear Medicine, University Hospital Giessen and Marburg, Marburg, Germany, [3]Department of Nuclear Medicine, Erasmus Medical Center, Rotterdam, Netherlands, [4]Department of Nuclear Medicine, University Hospital of Freiburg, Germany.

Background and aims: A reliable, non-invasive method that could quantitatively determine the pancreatic beta-cell mass *in vivo* would give further insight in the pathophysiology of type 1 and 2 diabetes. Such a test would allow monitoring effects of diabetes treatments on beta-cell mass, enable individually-tailored therapy and could be used to monitor islet transplantation. The GLP-1 receptor (GLP-1R) is expressed on pancreatic beta-cells. GLP-1, the natural ligand of the GLP-1R, cannot be used for *in vivo* GLP-1R targeting due to its low stability in plasma. Exendin-3 is a more stable analog of GLP-1 and therefore suitable for targeting of the GLP-1R. Exendin-3 was conjugated with DTPA, allowing radiolabelling with ^{111}In. We investigated the potential of SPECT imaging with ^{111}In-DTPA-Exendin-3 to determine the beta-cell mass *in vivo*.
Materials and methods: Diabetes was induced in Brown Norway rats by injecting different doses of alloxan (0, 15, 30, 45, 60 mg/kg) intravenously. Alloxan specifically destroys beta-cells in a dose-dependent manner. One week after alloxan injection, ^{111}In-labeled Exendin-3 was injected intravenously and SPECT images were acquired 1 hour post injection. After SPECT scanning the rats were euthanized and the radioactivity in the pancreas and relevant organs was measured and specific uptake in the Langerhans islets was determined by autoradiography. The beta-cell mass was determined by quantitative analysis of pancreatic sections that were stained immunohistochemically.
Results: In untreated rats, the pancreatic uptake of ^{111}In-DTPA-Exendin-3 was 0.15 ± 0.02 %ID/g. Treatment with 60 mg/kg alloxan resulted in a 80% reduction of pancreatic uptake of ^{111}In-DTPA-Exendin-3 (0.03 ± 0.02 %ID/g). *Ex vivo* autoradiography showed that ^{111}In-DTPA-Exendin-3 specifically accumulated in the endocrine pancreas. The pancreata of untreated rats were clearly visualized on the SPECT images acquired 1 h after injection of ^{111}In-DTPA-Exendin-3. After treatment with 60 mg/kg alloxan the pancreata were non-detectable by SPECT. There was a significant correlation between Exendin uptake and beta-cell mass (r=0.83). The uptake of Exendin as determined by quantitative analysis of the SPECT images correlated with the beta-cell mass (r=0.64).
Conclusion: ^{111}In-DTPA-Exendin-3 can be used to determine the pancreatic beta-cell mass non-invasively by SPECT. The uptake of the tracer is beta-cell specific. The uptake correlated linearly with beta-cell mass and disappeared in diabetic animals without remaining beta-cells. ^{111}In-DTPA-Exendin-3 is a promising tracer for the determination of the beta-cell mass. Clinical trials in healthy volunteers and type 1 diabetic patients are planned.

Autografting of BMSCs into miniature porcine pancreas for early phase of type 1 diabetes mellitus and tracing it by MRI *in vivo*

K. Tang[1], D. Liu[2], Y. Chen[3], Y. Wang[4], X. Yang[5], Y. Shen[5], H. Duan[5], H. Liang[5], M. Cai[5], J. Yan[5], Y. Zhu[5], J. Weng[5];
[1]Department of Geriatrics, Department of Endocrinology, Qilu Hospital of Shandong University, the 3rd Affiliated Hospital of Sun Yat-sen University, [2]Department of Vascular Surgery, the 1st Affiliated Hospital of Sun Yat-sen University, [3]Department of Radiology, the 1st Affiliated Hospital of Sun Yat-sen University, [4]Interventional Department, the 1st Affiliated Hospital of Sun Yat-sen University, [5]Department of Endocrinology, the 3rd Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background and aims: Recently, several researches in rodent animals and T_1DM patients indicated that T_1DM in the early stage might be reversed by autografting BMSCs (ABMSCs). However, the potential mechanisms remained unknown. The aims of the research are to disclose the efficiency and security of autografting BMSCs labeled by super-paramagnetic iron oxide (SPIO) quantitatively into the pancreas of minipig with T_1DM in early stage.
Materials and methods: Nine normal, healthy, 3-month old male Tibetan miniature pigs were randomized into 3 groups, including normal controls (NC), diabetic conventional therapy (DMC) and diabetic autografting BMSCs (DMAB) group. T_1DM pig model were induced by streptozotocin (STZ). T_1DM pigs were administrated with protamine zinc INS via subcutaneous injection to control fasting plasma glucose (FBG) level less than 10.0 Mm/L. In 4-6th wks after successful modeling, DMAB pigs accepted ABMSCs labeled by SPIO into the pancreas under the guidance of digital subtraction angiography. Blood routine biochemical parameters were determined to evaluate the security of ABMSCs at 4 timepoints. At the 3rd and 6th week after ABMSCs, the pancreases of DMAB animals were scanned by 3.0T MR. IVGTT and OGTT were used to evaluate pancreatic beta-cell function and glucose tolerance. Immunohistochemical examination were performed to estimate the regeneration of islets.
Results: After successful modeling, the diabetic animals' FBG were controlled at 5.1-12.5 Mm/L. DMAB group were treated with ABMSCs labeled with SPIO (7.4×10^7,6.8×10^7,7.0×10^7 cells, respectively) through dorsal pancreatic artery. The biochemical parameters of DMAB group had no significant change after ABMSCs. Comparing with pre-ABMSC, the MRI showed scattered low-signal area in the pancreases at the 3rd and 6th wk after ABMSCs. Before ABMSC, the INS dosage and FBG had no significant difference be-

tween DMC and DMAB group. At about 17 to 28 days after ABMSCs, FBG of DMAB group decreased progressively and waved between 2.3-7.5 Mm/L with INS free. IVGTT showed increased INS levels with a delayed peak at 10 min, and improved blood glucose tolerance gradually that had no significant difference comparing with baseline. Pathologic research showed that BMSCs labeled with SPIO differentiated into islet cells or pancreatic ductal epithelial cells in islets which showed positive response in brussian blue staining, and many small neogenetic intact islets in DMAB group and caritive ones in DMC group.
Conclusion: Our data suggested the security and efficiency of quantitative ABMSC through the femoral artery intervention for early stage T_1DM minipigs. ABMSCs could improve islet function effectively and maintain nearly normal FBG free from INS for a period of time. Autografting BMSCs could differentiate into islet cells or improve local microcirculation, and then reverse new-onset T_1DM.

Rapamycin impairs proliferation of transplanted islet beta cells
G. Parnaud, D. Bosco, T. Berney;
Cell Isolation and Transplantation Center, Department of Surgery, Geneva University Hospital and University of Geneva, Switzerland.

Background and aims: Five years after islet transplantation, only 10 % of patients remain insulin independent revealing a progressive islet dysfunction. The cause of this event is undefined to date but may be the result of adverse effects of immunosuppressive agents. In this study, we examined the effect of rapamycin, a key component of the immunosuppressive regimen in clinical islet transplantation, on islet cell replication *in vivo.*
Materials and methods: Streptozotocin (200 mg/kg i.p.) was used to induce diabetes in NOD/Scid mice at least 5 days before islet transplantation. Five hundred rat islets were transplanted under the left kidney capsule of normoglycemic or diabetic mice. Three days after transplantation, animals were randomly allocated into the experimental groups (control or rapamycin) and BrdU (5 mg/ml) was added to drinking water for 7 days. Mice were treated with rapamycin (0.3mg/kg/every day, i.p.) and control animals received appropriate vehicle treatment. An i.p. glucose tolerance test was performed on all animals at 10 days. Beta cell replication was determined by double immunofluorescence staining for insulin and BrdU. Data are expressed as % positive BrdU beta cells and as mean ± SEM for 3 or more independent experiments.
Results: Although control and rapamycin-treated mice had similar blood glucose levels before and 2h after i.p. glucose injection, both the peak glucose levels and duration of the glucose excursion (AUC in mM of glucose over 120 min) were increased in rapamycin-treated mice when compared to control mice (830±95 vs. 284±42; rapamycin vs. control, P=0.0004). In non streptozotocin-treated mice, rapamycin decreased the % of BrdU positive beta cells within endogenous islets (0.66±0.16 vs. 1.71±0.41; rapamycin vs. control, P=0.029). Furthermore, rapamycin reduced the % of BrdU positive beta cell in transplanted islets (0.71±0.16 vs. 4.60±0.42; rapamycin vs. control, P<0.0001). Similar results were obtained with Ki67 staining as an alternative mean of identifying proliferating cells (0.08±0.04 vs. 0.80±0.17; rapamycin vs. control, P=0.002). When streptozotocin-treated mice were treated with rapamycin, the % of BrdU positive beta cell in the graft was also significantly decreased (1.39±0.26 vs. 3.96±0.71; rapamycin vs. control, P=0.004). Finally, the apoptotic rate in transplanted islets was very low and no significant difference was observed between control and rapamycin-treated mice.
Conclusion: Our results indicate that rapamycin reduces the rate of pancreatic beta cell proliferation in transplanted rat islets but also in native pancreatic murine islets. It is therefore suggested that progressive graft islet dysfunction may result in part from an impairment of beta cell regeneration induced by rapamycin in transplanted patients.

Differences in blood perfusion correlates to pancreatic islet function *in vitro*
J.E. Svensson, J. Lau, P.-O. Carlsson;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: The blood perfusion between different pancreatic islets varies considerably. In recent experiments we observe that this result in a markedly heterogenous oxygenation of the islets. The present study tested the hypothesis that heterogeneity between islets with regard to vascular support is also reflected in differences in islet beta-cell function.
Materials and methods: Fluorescent microspheres (10 µm in size) were used to measure the blood perfusion of individual pancreatic islets in adult Wistar-Furth rats. Based on the microsphere distribution islets were separated into two groups, with blood flow below or above 0,4 µl/min. Functional studies of glucose-stimulated insulin release, insulin content and glucose oxidation rate were performed *in vitro* on freshly isolated islets. Gene expression studies were performed by RT-PCR. Vascular density quantification using two-photon confocal microscopy was performed separately for each group of islets after intravascular visualization of blood vessels by IB_4 isolectin.

Results: Functional studies on freshly isolated islets of the two groups revealed that islets with better blood perfusion had much higher basal and glucose-stimulated insulin release when compared to less perfused islets. No differences were observed between groups with regard to total insulin content, mitochondrial function, as assessed by studies of glucose oxidation rate, or in islet size. Vascular density quantification showed that approximately 10% of islets were composed of blood vessels in both groups, but that the vasculature in islets with lower blood perfusion had less tortuous architecture. Moreover, preliminary studies suggest that islets with better blood perfusion have higher gene expression of glucose transporter 2.
Conclusion: Our results indicate that pancreatic islets with higher blood perfusion also have better function that remains after isolation of the islets. This may partially be explained by differences in vascular structure, but need to be further investigated.

Hypoxia-protective effects of preconditioning in beta cells are exerted at the level of insulin biosynthesis and are mediated by inhibition of calcium inflow
A. Björklund[1], Z. Ma[1], V. Grill[2];
[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

Background and aims: Pharmacological preconditioning alleviates the impact of hypoxia in heart and brain; therefore similar procedures may also adapt beta cells to hypoxia prior to transplantation and this could be therapeutically useful. We have found that preconditioning in vitro by the K-ATP-channel opener diazoxide alleviates the diminution of cellular insulin contents brought about by experimental hypoxia on rat pancreatic islets. Here we report on possible mechanisms behind these beneficial effects.
Materials and methods: Rat or human islets were maintained in tissue culture (RPMI, 11mM glucose). They were subjected to 5.5 h of hypoxia with or without a 22h period of preconditioning with diazoxide and/or other agents.
Results: Rat islet insulin contents were reduced by 23 % after hypoxia and by 61% after a further 22 h re-oxygenation period. Preconditioning with diazoxide (325 µmol/l) alleviated the hypoxia effect (2.7 fold increase, $p < 0.001$ vs. hypoxia alone). Hypoxia reduced proinsulin biosynthesis (^{3}H-leucine incorporation into proinsulin) by 35 ± 6 % and this decrease was partially corrected by preconditioning (by 91 %, $p < 0.03$). Beneficial effects of diazoxide were abolished by including tolbutamide or elevated potassium (i.e. conditions which increase calcium inflow) during preconditioning. Preconditioning with 10 µmol/l of nifedipine, a calcium channel blocker, reproduced the beneficial effects of diazoxide. We employed cooling, i.e. culture at 28 C before hypoxia, to dissociate effects on insulin secretion (inhibited by cooling) from effects on calcium inflow (marginally affected by cooling). Cooling inhibited glucose induced insulin secretion by 64 ± 2 % but did not induce any positive preconditioning effect, instead a negative one was recorded (-40 ± 6 %). Both diazoxide and nifedipine moderately but significantly inhibited glucose oxidation before the period of hypoxia.
Conclusion: 1) hypoxia-induced functional deficits are alleviated by prior blocking of calcium inflow, probably acting through attendant effects on mitochondrial metabolism, 2) both agents which block calcium inflow indirectly and those which block directly have therapeutic potentials.

Composite pig islet-human endothelial progenitor cell grafts can reduce the instant blood-mediated inflammatory reaction
H.S. Jung[1], H.I. Kim[1], M.J. Kim[1], S.H. Hong[1], Y.Y. Lee[1], H.C. Jang[2], S.Y. Kim[2], K.S. Park[2];
[1]Seoul National University Hospital, [2]Seoul National University, Republic of Korea.

Background and aims: One of obstacles in clinical islet transplantation is the islet loss in the early post-transplant period, which is as much as 50-60% of the grafts. This mainly results from intravascular islet-induced nonspecific inflammatory and coagulation pathways promoting a so-called instant blood-mediated inflammatory reaction (IBMIR). Endothelial cells are known to protect against complement-mediated lysis and activation of coagulation. Endothelial progenitor cells (EPC) seem to have lower profile of procoagulation in some environment compared to mature endothelial cells. EPC can be isolated from peripheral blood, and be expanded ex vivo, which is important as for clinical application. In addition, EPC display a unique ability to promote angiogenesis although the underlying molecular mechanism remains poorly understood. These suggest that EPC might be a better source to protect IBMIR. Therefore, we tested effects of composite pig islet- human EPC grafts in vivo.
Materials and methods: Porcine islets were cocultured with human EPC overnight to obtain about 50% coverage. The cells were transplanted to STZ-diabetic athymic (nu/nu) nude mice through portal vein. Daily body weight and fed blood glucose were monitored, and serial harvest of liver tissues was performed for morphologic analysis.
Results: Composite pig islet-human endothelial progenitor cell grafts significantly improved blood glucose levels compared to islet grafts immediately after transplantation and then for 1 week, which suggested better graft survival from IBMIR. On morphologic examination, transplanted composite grafts showed a reduction in leukocyte infiltration and coagulation, and stained positive for insulin and human lectin demonstrating presence of both islets and EPC.
Conclusion: If optimal EPC-islet coculture method can be identified, EPC-coating has potential as a candidate that can control the strong innate immune response induced by islet grafts transplanted through the portal vein, and clinical islet transplantation would be more available and feasible strategy for the cure of diabetes.

Co-transplantation with mesenchymal stem cells improves islet transplantation outcome in mice
A.J.F. King, C. Rackham, P. Chagastelles, P.M. Jones;
Diabetes Research Group, King's College London, United Kingdom.

Background and aims: Islet transplantation is a potential cure for Type 1 diabetes, but despite recent advances most patients revert to hyperglycaemia within five years. It is thought lack of success may be partially due to beta cell death in the immediate post transplantation period and poor revascularisation. Mesenchymal stem cells (MSCs) are adult progenitor cells which play a major role in tissue repair. The aim of the study was to investigate whether co-transplantation of MSCs with islets could improve transplantation outcomes in mice.
Materials and methods: Mesenchymal stem cells were isolated from the kidneys of C57Bl/6 mice and were expanded *in vitro*. Islets were isolated from the pancreases of donor C57Bl/6 mice. Streptozotocin-diabetic C57Bl/6 mice were transplanted with a suboptimal graft of either 150 islets alone or 150 islets + 250,000 MSCs under the kidney capsule. Blood glucose concentrations were monitored for 28 days after which the graft-bearing kidneys of cured mice were nephrectomised. The islet grafts and endogenous pancreases were analysed histologically for insulin, glucagon and CD34 as markers for beta, alpha and endothelial cells, respectively.
Results: Prior to transplantation, blood glucose concentrations were 27.6 ± 1.8 mM and 28.2 ± 1.3 mM in the islet alone and islets + MSC groups, respectively. After transplantation, the mice that were implanted with islets + MSCs had lower blood glucose concentrations than mice implanted with islets alone (day 7: 11.6 ± 2.2 mM vs 27.5 ± 2.1 mM, day 14: 11.1 ± 2.1 mM vs 26.9 ± 2.0 mM, day 28: 8.6 ± 1.0 mM vs 19.0 ± 3.6 mM, n=9, $p<0.01$, 2 way RM ANOVA with Bonferroni Post-Hoc test). After 28 days, in cured mice (non-fasting blood glucose<11.1 mM: 8 of 9 mice in islets + MSC group, 3 of 9 mice in islet alone group) the graft bearing kidney was removed, after which all mice reverted to hyperglycaemia (>20 mM). The density of endothelial cells was increased in the islet + MSC grafts (978 ± 92 endothelial cells/mm^2) compared to the islet alone grafts (702 ± 23 endothelial cells/mm^2, n=4-6, $p<0.01$, t-test). No differences were seen in the endogenous pancreases between the two groups with regard to size of islets and frequency of insulin and glucagon staining, with most cells in the islet remnants consisting of alpha cells.
Conclusion: Co-transplantation with MSCs improves syngeneic islet transplantation outcome in mice. This is associated with increased numbers of endothelial cells in the graft and altered islet graft morphology. There is no difference in insulin positivity in the endogenous pancreases between the groups, indicating that the positive effects of MSCs are indeed a direct effect on the graft.

Gene transfer of glucagon-like peptide-1 to mouse islets improves transplantation outcome

S.-H. Ihm[1], M.-G. Choi[1], H.-J. Yoo[1], H.-S. Jun[2], J. Ihm[3];
[1]Internal Medicine, Hallym University, Chuncheon, [2]Lee Gil Ya Cancer and Diabetes Institute, Gachon University of Medicine and Science, Incheon, [3]Biochemistry, Kyonggi University, Suwon, Republic of Korea.

Background and aims: Pancreatic islet transplantation (TPL) is a promising therapeutic intervention for T1DM. One of the significant obstacles to successful islet TPL is a high number of cell deaths in islet grafts during the early days after TPL, mostly from inflammatory and hypoxic damage. To overcome these obstacles and improve the outcome of islet TPL, the transfer of cytoprotective genes to isolated islets has been attempted. Because glucagon-like peptide-1 (GLP-1) was shown to stimulate beta-cell proliferation and have anti-apoptotic effects on beta cells, we examined whether adenovirus-mediated gene transfer of GLP-1 would result in cytoprotection of islets in vitro and in vivo TPL setting.
Materials and methods: Isolated mouse islets were transduced with an adenoviral vector coding for GLP-1 (rAd-GLP-1) or green fluorescent protein/beta-galactosidase (rAd-GFP/LacZ). After transfection, GLP-1 expression was assessed by RT-PCR of islet mRNA and RIA of culture media. To assess the in vitro cytoprotective effect, transduced islets were treated with H2O2 (200 microM for 30 min) and cell death and MMP were measured using AO/PI and JC-1. To assess the effect of GLP-1 expression on islet survival in vivo, suboptimal mass of transduced islets was transplanted into renal subcapsular space of syngeneic diabetic mice.
Results: Adenoviral delivery of GLP-1 to islets resulted in dose (m.o.i.)-dependent increase in synthesis and secretion of GLP-1. Islets transduced with rAd-GLP-1 were protected from H2O2-induced cell damage in vitro. Two weeks after TPL, diabetes cure rate with islets transduced with rAd-GLP-1 (81%) was significantly higher than that with islets transduced with rAd-GFP/LacZ (25%).
Conclusion: Theses results indicate that the overexpression of GLP-1 in islets enhances islet survival in vitro and preserves islet function in transplants. Our results suggest that GLP-1 expression in islets is one of plausible and useful strategies for ex vivo cytoprotective gene therapy in islet TPL.

The thyroid hormone T3 improves function and survival of rat pancreatic islets during *in vitro* culture

C. Mangialardo, C. Verga Falzacappa, A. Stigliano, V. Toscano, S. Misiti;
II Faculty of Medicine, Sapienza, Università di Roma, Italy.

Background and aims: Islet cell transplantation is an alternative therapy to conventional ones for type 1 diabetic patients. However, this strategy is severely limited by the shortage of organ donors. Ex vivo islet cell culture prior to transplantation is a good alternative, but the maintenance of islets in culture is at the moment a difficult task. Therefore, stimulation of islet proliferation and differentiation in vitro remains the major scientific and clinical goal. Many growth factors have been studied, and related to intracellular signalling molecules and cell cycle regulators playing key roles in pancreatic beta cells. Among these, the kinase Akt has been indicated as a crucial intracellular mediator of beta cell growth and survival both in vitro and in vivo studies. We previously demonstrated that thyroid hormone T3 can increase beta cell function via specific activation of Akt, therefore we suggest that the addition of T3 to primary rat islets culture could preserve islets features from their physiological degradation, improving their status prior to transplantation.
Materials and methods: Rat pancreatic islets, isolated by collagenase digestion, have been cultured in the presence or not of T3 10-7M. Immunofluorescence analysis has been performed to evaluate the expression of thyroid receptor beta1 in rat islets. The islets viability has been studied by the use of two different dyes, one cell permeable green fluorescent dye and propidium iodide, and by the analysis of core cell damage upcoming. Beta cell proliferation within islets was analyzed by BrdU incorporation. Moreover, islet function has been evaluated by measuring insulin secretion. The ability of beta cells to counteract apoptosis induced by streptozotocin has been analyzed by TUNEL assay, and the Akt activation by Western blotting analysis.
Results: We demonstrated that treatment of primary cultures of rat pancreatic islets with T3 results in increased beta cell vitality with an augment of their functional properties. Contemporary a sensible reduction of the core damage has been observed in T3 treated islets, showing a preservation of the beta cells integrity during the culture period. Furthermore, when BrdU incorporation was performed, a much higher number of positive nuclei in T3 treated islets indicates that T3 not only improves islet status, but also that induces beta cell proliferation. Nonetheless, the insulin secretion is sensibly augmented after T3 stimulation. All the observed effects were associated with a strong increment in Akt activation, suggesting the involvement of this kinase in T3-mediated phenomena in pancreatic islets.
Conclusion: Our observations indicate the thyroid hormone T3 as a suitable factor to optimize and stimulate recovery and subsequent function of islets during in vitro culture suggesting that thyroid hormone could play an important role in physiological function of pancreatic islets.

Transcriptome analysis of type 2 diabetic islets: evidence of mitochondrial dysfunction

M. Bugliani[1], R. Liechti[2], L. Marselli[1], U. Boggi[1], F. Filipponi[1], I. Xenarios[2], P. Marchetti[1];
[1]University of Pisa, Italy, [2]Swiss Institute of Biostatistics, Vital-IT group, Lausanne, Switzerland.

Background and aims: Type 2 diabetes (T2D) is a multifactoral syndrome, with genetic and environmental factors causing a progressive beta cell dysfunction. The molecular alterations affecting T2D islets are not fully understood.
Materials and methods: We performed microarray analysis, followed by quantitative PCR of a few selected genes, of isolated islets from 6 T2D (age: 71±9 yrs; gender: 3M/3F; BMI: 26.0±2.2 Kg/m2) and 7 non-diabetic (ND, age: 58±17 yrs; gender: 4M/3F; BMI: 24.8±2.5 Kg/m2) subjects. RNA was hybridized on Affymetrix chips (HG U133A). After quality control by *affy* and *affyPLM*, gene expression intensity values were normalized by Robust Multi-array Average (RMA), whereas differential expression was assessed by *limma*. Functional studies were also performed with isolated islets.
Results: When T2D islets were compared to ND, the expression of 1345 probe sets resulted ($p<0.01$ and fold change of <0.5 and >2.0) different; of these, 59 were up-regulated and 1286 down-regulated. Overall, they identified 1230 genes, related to several beta-cell features. By using Gene Ontology and KEGG databases, we observed that those genes influenced 21 processes and 13 pathways, respectively. All the differences were confirmed by Gene Set Enrichment Analysis, which showed that, of the 1419 gene sets analyzed, 195 were positively and 42 negatively enriched in T2D samples. In all the analyses a reduction of the expression for genes involved in oxidative phosphorylation and citric acid cycle was observed. Accordingly, by qPCR a significant ($p<0.02$) decrease (-42%) of succinate dehydrogenase (SDH) subunit B expression was detected. When ND islets were exposed to methyl malonic acid, an inhibitor of SDH activity, a reduction (-33%) of glucose-stimulated insulin release was observed, that was accompanied by an alteration of the ADP/ATP ratio.
Conclusions: In conclusion, type 2 diabetic islets show many alterations of transcriptome, including changes of genes involved in mitochondrial ATP production; it remains to understand which alterations are cause or consequence of the diabetic condition.

Mitochondrial proteome analysis reveals changes in expression of multiple proteins in pancreatic beta cells exposed to high glucose

S. Muhammed[1], M. Ahmed[1], B. Kessler[2], A. Salehi[1];
[1]Clinical Science, Lund University, Malmö, Sweden, [2]Clinical Science, Oxford University, United Kingdom.

Aims: Chronic hyperglycemia leads to deterioration of insulin release from pancreatic β-cells as well as insulin action on peripheral tissues. However, the mechanism underlying β-cell dysfunction resulting from glucose toxicity has not been fully elucidated. The aim of present study was to define a set of alterations in mitochondrial profiles of pancreatic β-cell lines using two-dimension gel electrophoresis (2-DGE) and mass spectrometry.
Material and methods: INS1E cells were incubated in the presence of 5.5 and 20 mM glucose for 72 hrs. An aligate of media was removed for measurement of insulin release (RIA) and the cells were subjected then either for isolation of mitochondria or were frozen for western blot analysis , protein profile determined by two-dimension gel electrophoresis (2-DGE) and mass spectrometry.
Results: More than 400 spots were detected on the colloidal coomassie stained 2-D gels; of these protein spots, 75 displayed two fold or more significant change ($p>0.05$) in relative abundance in the presence of 20mM glucose compared to the control. Thirty-three protein spots appear only on the control mitochondrial map. Mitochondrial proteins down regulated in glucotoxic conditions includes ATPsynthase α chain and δ chain, malate dehydrogenase, aconitase, trifunctional enzyme β subunit, NADH-cytochrome b5 reductase and VDAC2.There was up regulation of VDAC1, GPR75, HSP60 and HSP10. Protein identification revealed contamination of the mitochondrial fraction with proteins from other organelles. These differentially expressed proteins includes proinsulin, calreticulin, PD1A6, PKCsubstrate60.1kDa protein ORP150, endopalsmin, HSC70, heterogeneous nuclear rib nucleoproteins D0 and A2/B1, lamin B1, histones H2B, H3.3 and H4 and elongation factor 1-α-1. In conclusion, orchestrated changes in expression of VDAC and multiple proteins involved in nutrient metabolism, ATP synthesis, cellular defence, glycoprotein folding, apoptosis signaling and mDNA stability may explain cellular dysfunction in glucotoxicity resulting in altered insulin secretion.

Novel islet respirometry assay reveals high levels of uncoupled respiration in rodent and human islets

J.D. Wikstrom[1], A. Elorza[2], E.M. Allister[3], L. Stiles[4], S.B. Sereda[1], G. Las[1], M.B. Wheeler[5], D.A. Ferrick[6], O.S. Shirihai[1];
[1]Medicine, Boston University, Boston, USA, [2]Departamento de Biologia, Universidad Andres Bello, Santiago, Chile, [3]Departments of Physiology and Medicine, University of Toronto, Canada, [4]Medicine/Pharmacology, Boston University/Tufts University, Boston, USA, [5]Departments of Physiology and Medicine, University of Toronto, Canada, [6]Seahorse Bioscience, Billerica, USA.

Background and aims: Mitochondrial metabolism is essential for proper insulin secretion as oxidative phosphorylation produces the majority of the cells ATP required for insulin granule exocytosis. However, mitochondrial substrate oxidation is not fully coupled to ATP synthesis as part of the proton gradient across the inner mitochondrial membrane reenters the matrix through other ways than ATPsynthase; this is termed uncoupled respiration or proton leak. In this study we sought to characterize the basal proton leak of intact islets, it's regulation as well as its profile in diseased islets.
Materials and methods: To enable this study we developed a high-throughput islet respirometry approach based on the XF24 platform, originally designed to study monolayers of cells. By applying drugs that act on the respiratory chain we can estimate the level of fuel-stimulated, uncoupled, maximal as well as non-mitochondrial respiration under various conditions. Islets were derived from wildtype and high fat diet fed C57Bl6/J mice as well as from human donors.
Results: When stimulated with fuels mouse islets displayed a marked increase in respiration. The basal level of islet uncoupled respiration was measured to 55%, strikingly higher than other cell types. We found that cellular fuels such as amino acids, free fatty acids and glucose significantly uncouple islet mitochondria and that this is prevented by antioxidants. Further we found that the adenine nucleotide transporter, but not the permeability transition pore, makes a significant contribution to the proton leak. In vitro incubation with palmitate did not affect the level of uncoupled respiration under low glucose, but had a significant effect when the islets were stimulated with high glucose. Further, islets from high-fat diet-fed mice exhibited higher levels of uncoupled respiration compared to islets from chow fed control animals. Islets with beta-cell specific deletion of uncoupling protein 2 (UCP2) were found to exhibit normal levels of uncoupled respiration pointing to UCP2 not being a major contributor to the measured uncoupled respiration. In addition to the studies on mouse islets, human islets from healthy as well as diabetic donors were tested. Human islets also display high levels of uncoupled respiration that is increased by high glucose.
Conclusion: Islets have relative high levels of uncoupled respiration, which is regulated by cellular fuels and reactive oxygen species. Adenine nucleotide transporter but not UCP2 or permeability transition pore appears to contribute to the observed uncoupled respiration. Interestingly levels of uncoupled respiration increase in a diabetes animal model. In principle, tuning islet mitochondrial efficiency may represent a therapeutic target.

Oxidative phosphorylation-dependent insulin secretion in pancreatic beta cells: new insights by disrupting TFB1M

T. Köck, P. Spégel, V.S. Sharoyko, C. Ling, H. Mulder;
Clinical Sciences in Malmö, University Malmö Hospital, Sweden.

Background and aims: Oxidative phosphorylation (OXPHOS) is a mitochondrial metabolic pathway that uses energy released by the oxidation of nutrients to produce ATP. It depends on the functional status of the mitochondrial electron transport system (ETS). Disrupting the mitochondrial transcription factor B1 (TFB1M) impairs the function of the ETS complexes

as TFB1M regulates the translation of mitochondria encoded subunits. The fact that these subunits are of different importance for the individual ETS complexes allows us to investigate the metabolic regulation of the ETS activity, OXPHOS, and therefore insulin secretion in glucose-responsive INS-1 832/13 clonal beta-cells in detail.
Materials and methods: Knock down (KD) of TFB1M was achieved by RNA interference. Oxygen consumption rates were measured using the Seahorse Extracellular Flux Analyzer XF24. Stable isotope-labeling with amino acids in cell culture (SILAC) and immunoprecipitation were used for proteomic analysis of the ETS complexes. ATP levels were detected by luciferase assay. Insulin secretion was determined by RIA.
Results: SILAC analysis and detection of TFB1M by immunoblotting confirmed its knock down by more than 50% in INS-1 cells. In intact cells, as predicted, TFB1M knock down significantly decreased the glucose-stimulated ADP-activated coupled OXPHOS capacity P (10.9 +/- 0.3 nmol O2/min/mg protein vs. 9.0 +/- 0.5 nmol O2/min/mg protein; P<0.01) and electron transport capacity E of the ETS (15.5 +/- 0.5 nmol O2/min/mg protein vs. 12.1 +/- 0.9 nmol O2/min/mg protein; P<0.05) as well as mitochondrial ATP generation and triggering pathway-dependent insulin secretion. Immunoblotting and SILAC analysis showed a decreased expression level of nucleus and mitochondria encoded ETS subunits, foremost of complex I, which also showed the most extensive decrease in activity to 40.7 +/- 2.8 % of the activity in control cells. Consistently, measurements with defined metabolic substrates supporting ETS complex I activity in permeabilized cells demonstrated that P (47.9 +/- 0.8 nmol O2/min/mg protein in control vs. 33.9 +/- 1.3 nmol O2/min/mg protein in TFB1M KD; P<0.01) and E (75.3 +/- 5.9 nmol O2/min/mg protein in control vs. 50.4 +/- 3.5 nmol O2/min/mg protein in TFB1M KD; P<0.01) were affected significantly. However, measurements with substrates employing complex II showed no significant differences in P and E, despite pronounced TFB1M knock down-dependent decreases in complex III and IV activity to 60.1 +/- 4.7 % and 74.5 +/- 3.5 % of the activity in control cells, respectively.
Conclusion: (1) ETS complex I activity is rate-limiting for the metabolite-stimulated electron transport of the ETS and therefore OXPHOS and ATP generation in beta-cells. (2) 832/13 clonal beta-cells employ significant excess capacity of complex III and IV activity (3) Mitochondrial OXPHOS is crucial for the fuel stimulation of insulin secretion. (4) In INS-1 832/13 clonal beta-cells, disruption of mitochondrial translation profoundly affects mitochondrial function, predominantly by diminished complex I stability. Thus, based on these novel findings, further studies concerning the mechanisms of metabolic regulation of ETS activity and OXPHOS and therefore mitochondria-based metabolic coupling of insulin secretion open a new avenue for research in pancreatic islet cell biology.

The Atp8 mutation of complex V impairs secretory function of beta cells - role of mitochondrial ROS and ATP in response to glucose challenge
H. Weiss[1], C. Koch[1], L. Wester-Rosenloef[1], S. Ibrahim[2], M. Tiedge[1];
[1]Institute of Medical Biochemistry and Molecular Biology, University of Rostock, [2]Department of Dermatology, Allergology and Venereolgy, University of Lübeck, Germany.

Background and aims: The conplastic mouse strain B6mt^{FVB} carries a stable mtDNA mutation of the *Atp8* gene affecting the assembly of the Fo subunit of the ATP-synthase complex. It was the aim of the study to correlate secretory responsiveness to glucose with ATP/ADP levels and mitochondiral ROS generation in comparison to the B6mt^{AKR} control strain.
Materials and methods: B6mt^{FVB} and B6mt^{AKR} were regularly monitored for blood glucose and tested for glucose tolerance feeding standard diet. Pancreatic islets were isolated from normoglycaemic mice (age 12 - 16 weeks) and cultured at 5 or 30 mmol/l glucose for 24 h and 48 h. Production of mitochondrial superoxides was measured by the Mitosox^{TM} indicator using fluorescence microscopy. Cellular ATP and ADP levels in isolated islets were measured by a luminometric assay. Glucose stimulated insulin secretion of isolated islets was measured by ELISA.
Results: B6mt^{FVB} as well as B6mt^{AKR} mice showed normal blood glucose levels (5.8 ± 0.4 vs. 6.8 ± 0.6 mmol/l). Both strains showed a normal glucose tolerance when challenged with 1 g glucose/kg b. wt. Exposure of isolated B6mt^{FVB} islets to 30 mmol/l glucose for 24 h or 48 h resulted in a significant decrease of glucose-stimulated insulin secretion by 80 % ($p < 0.001$) and 50 % ($p < 0.05$) in comparison to B6mt^{AKR} islets. Basal as well as glucose-stimulated (2.8 vs. 20 mmol/l) insulin secretion were not different between the two mouse strains when the islets were pre-cultured at 5 mmol/l glucose for 24 h or 48 h. Islets from B6mt^{AKR} mice showed a 4-fold increase of ATP levels when glucose concentrations were increased from 2.8 to 20 mmol/l. ATP levels in islets from B6mt^{FVB} mice were insensitive to changes of glucose. The ATP/ADP ratio was 2.5-fold higher in islets from B6mt^{AKR} mice in comparison to the B6mt^{FVB} strain after 24 h preculture at 30 mmol/l glucose. In islets from B6mt^{FVB} mice mitochondrial ROS generation increased significantly at 30 mmol/l glucose while there were only slight increases in islets from B6mt^{AKR} mice. However, mitochondrial ROS generation at 5 mmol/l glucose was higher in islet cells from B6mt^{AKR} mice than in islets from the B6mt^{FVB} strain. Preculture of islet cells at 30 mmol/l glucose for 24 h or 48 h did not significantly affect cell viability in the B6mt^{FVB} and B6mt^{AKR} strain.
Conclusion: The beta cell dysfunction in islets with the *Atp8* gene mutation is plausibly explained by reduced ATP production through complex V of the respiratory chain. In line with metabolic stimulus-secretion coupling this resulted in reduced glucose-responsiveness of insulin secretion. Mitochondrial ROS generation in B6mt^{FVB} islets is more sensitive to high glucose than in B6mt^{AKR} islets. Our data provide evidence that in islets with *Atp8* gene mutations adaptive changes of mitochondrial ROS generation rather than absolute levels are important to induce beta cell dysfunction under conditions of nutrient stress.

Marked, but not moderate induction of uncoupling protein 2 enhances selected aspects of beta cell mitochondrial metabolism and decreases susceptibility to toxicity
I. Hals[1], Z. Ma[2], H. Ogata[1], A. Björklund[2], V. Grill[1,2];
[1]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway, [2]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: The effects of uncoupling protein 2 (UCP-2) for mitochondrial metabolism, for beta cell function and for propensity of diabetes have been intensely studied. However, because of conflicting results no agreement on the role(s) of UCP-2 has been reached. Different degrees of induction or inhibition of UCP-2 between studies could be an important but unexplored reason for conflicting results. Here we investigated effects of a fourfold induction on mitochondrial, insulin and toxicity parameters and tested for replication of positive findings at a lower level of induction.
Materials and methods: We transfected INS-1 cells to obtain a tet-on inducible cell line. A 48 h exposure to 1 μg/ml of dox induced UCP approximately fourfold (424 ± 113 %, mean ± SEM) and 0.1 μg/ml twofold (178 ± 29%, n = 3).
Results: Fourfold induced cells displayed normal mitochondrial membrane potential (by Rhodamine 123), normal mitochondrial mass (Mitotracker Green) and normal ATP levels. By immunoblotting subunits of complex 1 (ND6) and 2 (FeS) and 4 (COX I) were not changed. However, core2 for complex III was up-regulated 17 %, and α subunit for complex V by 20%. Glucose oxidation (at 11 mM glucose) was not significantly affected (+5 ± 9 %, n = 6), however, oxidation of fatty acids (^{14}C-oleate) was increased by 35 ± 15 % ($p < 0.05$, n = 12). Cellular insulin contents (-4 ± 7 %, n = 3) and glucose-induced insulin secretion were not affected (+27 ± 11 %, n = 5), nor insulin responses to oleate. A fourfold induction protected against H_2O_2-induced toxicity by 22 ± 5 % ($p < 0,01$, n = 8, MTT assay and flow cytometry). However, the lower (approximately two-fold) induction of UCP-2 did not reproduce mitochondrial and metabolic effects, nor protection against toxicity effects (and susceptibility towards the latter was not aggravated by UCP-2 down-regulation by siRNA).
Conclusion: A fourfold induction of UCP-2 induces subtle but definite enhancing effects on mitochondrial metabolism and also toxicity protection. However, lack of reproducibility at lower levels of induction as well as lack of a negative effect on insulin parameters argues against an important role of UCP-2 in beta cells in diabetes.

Cytosolic phosphate, a regulator of mitochondrial function in insulin-secreting cells

K.-S. Park[1,2], X. Quan[1], R. Das[1], S. Xu[1], A.C. Wiederkehr[2], C.B. Wollheim[2];
[1]Physiology, Yonsei University, Wonju College of Medicine, Wonju, Republic of Korea,, [2]Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: Mitochondrial energy metabolism depends on the continued uptake of ADP and inorganic phosphate as substrates of the ATP synthase and the export of the product ATP from the organelle. The exchange of ATP against ADP is mediated by the adenine nucleotide translocase (ANT). Uptake of inorganic phosphate by mitochondria is linked to the net uptake of one proton per phosphate anion. Here we tested whether inorganic phosphate regulates mitochondrial energy metabolism in INS-1E cells in addition to its role as a substrate for the ATP synthase.
Materials and methods: Mitochondrial ATP synthesis was studied in staphylococcal alpha-hemolytic toxin permeabilized INS-1E cells. This treatment leaves the membranes of intracellular organelles such as mitochondria intact and allows us to distinguish between intraorganellar ATP and the ATP pool released from mitochondria. ATP was measured with a bioluminescence assay. A fluorescence microscopic imaging system was used to study the mitochondrial matrix pH and a microplate reader to record the mitochondrial membrane potential with JC-1.
Results: Permeabilised INS-1E cells showed mitochondrial membrane hyperpolarisation and matrix alkalinization in response to substrates such as succinate or glycerolphosphate. We find that the hyperpolarisation was strongly dependent on the extramitochondrial phosphate concentration. Phosphate addition alone induced mitochondrial matrix acidification in permeabilised cells. Matrix alkalinization induced by succinate was less dependent on the extramitochondrial phosphate concentration than mitochondrial hyperpolarisation. ATP release from mitochondria induced by substrate but not the increase of the organellar pool of ATP was completely blocked by atractyloside, an inhibitor of the ANT. ATP release was also strictly dependent on the presence of extramitochondrial ADP, implying that ATP release from mitochondria is exclusively dependent on ANT activity. Upon stimulation with mitochondrial substrates, the amount of ATP exported from mitochondria was markedly accelerated by increased phosphate concentrations contrasting with the modest elevation of ATP inside the mitochondria.
Conclusion: We demonstrate that the cytosolic phosphate concentration has a strong impact on the mitochondrial electrochemical gradient, ATP synthesis and ATP export from the organelle. Our results suggest that inorganic phosphate affects mitochondrial energy metabolism beyond its role as a substrate for ATP synthesis. As large changes in phosphate transport across the plasma membrane have been reported in islets, our results emphasize the importance of cytosolic inorganic phosphate concentrations in metabolism-secretion coupling.

PS 29 Glucose and mitochondrial metabolism

Naturally occurring glucokinase mutations at the same amino acid residue cause opposite clinical phenotypes of hypo- and hyperglycaemia

N.L. Beer[1], N.D. Tribble[1], K. Colclough[2], P. Arundel[3], J. Grimsby[4], C. Chik[5], S. Ellard[2], A.L. Gloyn[1];
[1]OCDEM, University of Oxford, [2]Royal Devon & Exeter NHS Trust, Exeter, [3]Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom, [4]Department of Metabolic Disease, Hoffman-La Roche Inc., Nutley, USA, [5]Division of Endocrinology & Metabolism, University of Alberta, Edmonton, Canada.

Background and aims: Glucokinase (*GCK*) mutations cause disorders of glucose homeostasis. Heterozygous activating and inactivating mutations cause hyperinsulinaemia of infancy (HI) and maturity-onset diabetes of the young (MODY) respectively. Activating mutations cluster at the allosteric activator site, a target for pharmacological GCK activators (GKAs) which are currently in development. This study reports 2 novel activating mutations (V389L & T103S), at residues where GCK-MODY mutations (V389D & T103N) have also been reported. We hypothesised that the physiochemical properties and position of the substituted residue could result in opposite phenotypes. We structurally and functionally characterised these mutations in the presence and absence of GCK regulators, providing further insight into critical residues within this important drug target.
Materials and methods: Recombinant human wild-type (WT) GCK and all 4 mutants were generated. Enzyme kinetic activity was determined spectrophotometrically using an $NADP^+$-coupled assay. Kinetic characteristics and responses to the physiological inhibitor glucokinase regulatory protein (GKRP) and pharmacological GKA RO0281675 were calculated. Structural modelling and bioinformatic analysis were performed using PyMOL.
Results: Both HI mutations were kinetically activating with relative activity indices (RAI) of 6.0 and 8.4 for V389L and T103S respectively (vs 1.0 for WT). This higher activity was driven by an increased affinity for glucose (glucose $S_{0.5}$ 3.5 ± 0.1 for V389L, 3.3 ± 0.1 for T103S, 7.5 ± 0.1mM for WT). The MODY mutation V389D had dramatically decreased enzyme activity (RAI <0.1). Paradoxically the T103N MODY mutation was mildly kinetically activating ($S_{0.5}$ 5.8 ± 0.1mM, K_{cat} 51.5 ± 1.1S^{-1}, RAI 1.5). Inhibition assays showed a similar response to GKRP for WT and V389L (IC_{50} both 1.1 ± 0.1 GKRP units), whilst T103S and -N had decreased affinity (1.5 ± 0.1 and 1.9 ± 0.1 respectively). All mutations responded to the GKA; T103N had a similar fold increase in $K_{cat}/S_{0.5}$ to WT (18.0 ± 1.5 vs 14.4 ± 0.3 respectively), whilst that for T103S & V389L was lower (5.7 ± 0.5 and 7.4 ± 1.3 respectively). V389D $K_{cat}/S_{0.5}$ increased considerably (33.9 ± 2.1). V389 lies within an α-helix, with both mutations causing extra intra-helical bonds. T103 is in a β-sheet close to the allosteric activator site, both mutations losing an intra-strand bond whilst forming new polar interactions.
Conclusion: Different physiochemical properties of substituted residues within GCK can determine clinical phenotype. V389 (or its α-helix) is integral to protein activity, with its mutation affecting glucose turnover. T103 lies in a β-sheet close to the allosteric activator site. Both T103S/N have increased GCK activity, suggesting the pathogenesis for T103N may be due to catalytic instability (reflected by decreased GKRP affinity). Our study has implications for drug development, as it demonstrates a fine balance between catalytic and structural stability upon intervention at certain GCK residues/areas of GCK secondary structure.

Identification of an ubiquitin-like domain as a potential new interaction partner of glucokinase in pancreatic beta cells

A. Brix[1], K. Kollmann[1], S. Langer[1], S. Lenzen[1], S. Baltrusch[2];
[1]Institute of Clinical Biochemistry, Hannover Medical School, [2]Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

Background and aims: In pancreatic beta cells, glucokinase (GK) acts as a glucose sensor and catalyzes the rate-limiting step for initiation of glucose-induced insulin secretion. GK is mainly regulated on the posttranslational level by protein-protein interactions. The bifunctional enzyme 6-phosphofructo-

2-kinase/fructose-2,6-bisphosphatase serves as an activating GK interaction partner in both, beta cells and liver. In contrast an inhibiting GK protein, the GK regulatory protein is only expressed in liver, but not in beta cells. This raised the question whether unidentified beta cell specific GK interaction partners exist. Therefore the aim of this study was to identify beta cell specific GK interaction partners through a yeast two hybrid (YTHS) screening of a rat islet library.
Materials and methods: RNA isolated from rat pancreatic islets was used to generate a cDNA library by SMART technology (Clontech). Recombination of the cDNA library with the pGADT7-R vector was performed in S. cerevisiae AH109. Mating with the pGBKT7-GK containing S. cerevisiae Y187 yeast strain was established resulting in analysis of 5.5 x 10^5 clones in three independent runs. Initially positive clones were characterized by histidine (His) and adenine (Ade) reporter gene assays in yeast. Thereafter binding to GK was determined in MIN6 beta cells using a recently established fluorescence based mammalian two-hybrid system (MMTHS) in a high-throughput scanR (Olympus) microscopy setup.
Results: 73 positive clones were selected by His reporter gene expression in yeast, whereas four clones showed also significant Ade reporter gene expression. In YTHS experiments with the control plasmid lamin only one clone exhibited specific interaction with GK. Sequence and protein database analyses revealed a 180 amino acid containing protein fragment with homology to the N-terminal part of midnolin 2 of mus musculus. Thus, no full-length protein was discovered. However, a complete sequence of an ubiquitin-like domain (UbD) consisting of 72 amino acids was identified inside of the protein fragment by NCBI-BLAST data base analyses and further analyzed in the MMTHS. For this the UbD was subcloned in frame with the binding domain (pBIND-ECFP-UbD), and interaction with GK subcloned in frame with the activation domain (pACT-GK) in comparison to control (pACT) was elucidated in single MIN6 beta cells. Interestingly, a specific interaction between the UbD and GK determined as an increase of the EYFP reporter gene expression in relation to the constitutively expressed ECFP fluorescence over time was elucidated.
Conclusion: We have identified an ubiquitin-like domain as a potential new GK binding partner. Recently an ubiquitin interacting motif has been discovered in GK. As the ubiquitin-proteasome pathway plays an important role in pancreatic beta cells our study supports the hypothesis of GK regulation by ubiquitination.

The novel naturally occurring activating glucokinase gene mutation E442K maintains INS-1E cell proliferation and protects against glucose-induced apoptosis
A.L. Cuesta-Muñoz[1], N. Cobo-Vuilleumier[1], R. Araujo[2], P. Rodriguez-Bada[1], A. Gavito[1], E. Baixeras[1], F. Martin[2], F. Bedoya[3], A. Bernad[4], B. Gauthier[5];
[1]Centre for the Study of Pancreatic Beta-cell Diseases, IMABIS Foundation, Málaga, [2]Pancreatic Islets and Stem Cells, CABIMER, Sevilla, [3]Celular Therapy and Regenerative Medicine, CABIMER, Sevilla, [4]Regenerative Cardiology, CNIC, Madrid, [5]Pancreatic Islet Development and Regeneration, CABIMER, Sevilla, Spain.

Background and aims: In addition to its glucose sensor function in islet beta cells, glucokinase (GK) has recently been proposed to participate in cell proliferation and survival. These GK-mediated effects appear to require IRS-2 and BAD, respectively. We have previously described in humans two novel mutations located almost contiguously in the same domain of GK yet having opposite clinical phenotypes: a naturally inactivating (*GCK*-E440G) and activating *(GCK*-E442K) GK mutations which cause monogenic diabetes and congenital hypoglycaemia, respectively. In order to establish a potential link between GK activity and beta cell survival as well as expansion, we constitutively expressed these mutant variants in the insulinoma INS-1E cell line.
Materials and methods: Using lentiviral technology, we created stable clones of INS-1E cells constitutively expressing GK (INS-1E-cmv.GCK-WT.ires.GFP), the two mutant variants (INS-1E-cmv.GCK-E440G.ires.GFP, INS-1E-cmv.GCK-E442K.ires.GFP) or the control GFP lentiviral vector (INS-1E-cmv.ires.GFP). Transcript levels for GK, E442K, E440G, GFP, BAD and IRS2 were determined by quantitative real time RT-PCR (QT-PCR). Acute insulin secretion in response to glucose (3 and 15 mM) was also measured. In addition, the impact of increasing concentration of glucose (3, 11 and 20 mM) on proliferation and survival was estimated at 72 hours.
Results: Overexpression of GK or E442K in INS-1E did not alter glucose-induced insulin secretion (GSIS) as compared to control GFP cells. In contrast, overexpression of the inactivating mutation E440G resulted in impaired GSIS. QT-PCR revealed that both the GK and E442K transcript were expressed at similar levels whereas E440G was at least 5-fold higher, explaining the potential altered GSIS. Similar results were found with GFP transcript levels. Interestingly, BAD and IRS2 expression levels remained unaltered in all clones as compared to control GFP cells. More importantly, our results showed that after 72 hours at either 3 mM or 20 mM glucose, the clone expressing the E442K variant displayed significantly reduced apoptosis (12- and 6-fold, respectively) whereas the E440G only protected cells at low (2-fold) but not at high glucose as compare to GFP expressing cells. GK had no protective effect. In contrast all clones exhibited protection at 11 mM glucose (6-fold as compared to GFP), corresponding to normal culture conditions. Proliferation at 11 or 20 mM glucose was identical for all clones. Astonishingly, the E442K clone was also able to sustain proliferation even at 3 mM glucose.
Conclusion: Taken together, our results indicate that the naturally occurring activating mutation GK-E442K may convey protection and maintain proliferation of β-cells under altered glycaemic conditions. Yet, the fact that the inactivating mutation GK-E440G, located in the vicinity of the E442K, also protects at low glucose suggests an insulin independent effect. We are currently investigating a potential link between the BAD protein and these mutant variants in β-cell survival.

Activation of PPARδ promotes mitochondrial energy metabolism and decreases basal insulin secretion in palmitate-treated beta cells
L. Jiang, J. Wan, L.-Q. Ke, Q.-G. Lü, N.-W. Tong;
Sichuan University, Chengdu, China.

Background and aims: The peroxisome proliferator-activated receptor δ(PPARδ)regulates the expression of genes involved in cellular lipid and cell energy metabolism in many metabolically active tissues, such as liver, muscle and fat and plays a role in the cellular response to stress and environmental stimuli. The particular role of PPARδ in insulin-secreting beta-cells, however, is not as well understood; therefore, our aim was to investigate the cell-specific role of PPARδ on mitochondrial energy metabolism and insulin secretion in beta-cells.
Materials and methods: After exposing a Syrian hamster pancreatic beta-cell line, HIT-T15, to high-concentrations of palmitate and/or the specific PPARδ agonist GW501516, we detected the gene expression changes for transcripts associated with mitochondrial biogenesis, such as peroxisome proliferator-activated receptor gamma co-activator 1 (PGC-1α), nuclear respiratory factor 1 (NRF-1), mitochondrial transcription factor A (mtTFA), using real-time quantitative polymerase chain reaction (RTQ-PCR). The protein levels of the mitochondria uncoupling protein 2 (UCP2) were measured by western blot analysis; the insulin secretion capacity and ATP/ADP ratio were analyzed using enzyme linked immunosorbent assay (ELISA) and high performance liquid chromatography, respectively.
Results: Activation of PPARδ promoted generation of mitochondrial ATP, as well as expression levels of PGC-1α, NRF-1 and mtTFA in palmitate-treated HIT-T15 cells. Activated PPARδ also decreased basal insulin secretion, but had no effect on glucose-stimulated insulin secretion (GSIS) via increased amounts of UCP2.
Conclusion: GW501516 treatment enhanced mitochondrial energy metabolism, but it also promoted a concomitant mitochondrial uncoupling and resulted in decreased basal insulin secretion and restricted GSIS. Activation of PPARδ induced a reduction of basal insulin secretion, but did not appear to improve GSIS; this observation indicated the possible action of a protective mechanism responding to the alleviation of basal insulin load in lipotoxic beta-cells.

Role if tissue specific alterations of mitochondrial dynamics in development of type 2 diabetes
J. Schultz, S. Baltrusch;
Institut of Medical Biochemistry and Molecular Biology, Rostock, Germany.

Background and aims: Mitochondrial dysfunction has been proposed to play an important role in the development of type 2 diabetes. Mitochondrial function is regulated in a tissue specific manner and in recent studies mitochondrial dynamics have been elucidated to be important to maintain cellular metabolism. Mitochondria constitute a mobile network that continuously

cycle through fusion and fission events. By this process dysfunctional mitochondria are segregated and their removal by autophagy is initiated. Mitofusin 1 and 2 (Mfn1 and Mfn2) and the optic atrophy 1 (Opa1) are essential for mitochondrial fusion, whereas the fission protein 1 (Fis1) and the dynamin related protein 1 (Drp1) control fission. Alterations in mitochondrial function may be evoked by obesity, and thus, crucial to explain both insulin resistance in peripheral tissue and pancreatic beta cell dysfunction resulting in impaired insulin secretion in type 2 diabetes. Therefore the aim of this study was to investigate tissue specific alterations in mitochondrial dynamics in obese ob/ob mice compared to normal weight control mice.
Materials and methods: Islets from obese ob/ob mice (B6.V-lebob) and control mice (C57BL/6J) were isolated by collagenase digestion. Furthermore liver, muscle, adipose tissue and brain were taken from ob/ob and control mice. RNA and protein were isolated and quantitative Real-Time PCR analyses and western blot analyses of Fis1, Drp1, Opa1, Mfn1 and Mfn2 were carried out, respectively. Additionally frozen sections were made for immunofluorescence analyses.
Results: Gen expression of Fis1, Drp1, Opa1, Mfn1 and Mfn2 in islets of obese ob/ob mice was significantly reduced compared to control mice and the resulting expression pattern indicated an imbalance of mitochondrial fusion and fission processes. In liver Fis1 was down regulated in ob/ob mice compared to control, while Drp1 was up regulated. As both proteins cannot replace each other, fission was disturbed in liver of ob/ob mice. Furthermore immunofluorescence analyses revealed an inhomogeneous expression pattern of fission proteins in liver of ob/ob mice. Additionally Mfn1 and Mfn2 were significantly reduced on the gene as well as protein level in liver of ob/ob mice. Interestingly Mfn2 a protein which plays a role in mitochondrial substrate oxidation was significantly down regulated in islets, liver, muscle and adipose tissue, but not in the brain of ob/ob mice compared to control. Gene and protein expression of Fis1, Drp1, Mfn1 and Mfn2 was reduced in adipose tissue and muscle of ob/ob mice compared to control, but in muscle to a much higher extent. Solely in muscle a significant down regulation of the Opa 1 protein was determined.
Conclusion: We have observed tissue specific changes in mitochondrial dynamic in obese mice compared to normal weight control mice. In future experiments we will elucidate whether these alterations are a reversible adaptive process maintaining cell function or represent mitochondrial dysfunction. In conclusion, our study provides further evidence that obesity induced mitochondrial alterations contribute to the development of type 2 diabetes.

Implication of mitochondria in IAPP induced-beta cell toxicity
M. Soty, M. Visa, L. Cadavez, M. Carmona, A. Novials;
Laboratori de Diabetis i Obesitat, IDIBAPS, Hospital Clínic, CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

Background and aims: Type 2 diabetes is characterised by islet dysfunctions that lead to the impairment of insulin secretion. The presence of islet amyloid deposition is a recognised hallmark in islets of type 2 diabetes patients. Amyloid fibrils are formed by human islet amyloid polypeptide (hIAPP). There is now very strong evidence supporting the key role of amyloidogenesis in the progressive loss of pancreatic beta-cell mass and function. Mitochondria have a central role in the regulation of insulin secretion since the latter is largely controlled by ATP production through oxidative phosphorylation (OXPHOS) taking place in the mitochondrial respiratory chain. The main objective of this project is to investigate whether mitochondria may play a role in the mechanisms by which human IAPP induces beta-cell cytotoxicity.
Materials and methods: The rat pancreatic beta-cell line INS1E was stably transfected with a *hIAPP* plasmid (hIAPP cells) or pcDNA3 (control cells). In order to characterise the impact of hIAPP on beta-cell function, we measured insulin and IAPP secretion and intracellular calcium mobilisation in response to glucose. Calcium levels were measured using Fura-2 labelling. Mitochondrial function was explored by monitoring cellular respiration, mitochondrial membrane potential and reactive oxygen species (ROS) production. Rhodamine 123 and CM-H2DHCFA probes were used to monitor membrane potential and ROS levels, respectively.
Results: In response to 16,7 mM glucose, insulin and IAPP secretion was strongly decreased in hIAPP compared with control cells (3.5 ± 0.7 *vs* 15.6 ± 2.9 % insulin release expressed as a percentage of cellular insulin content and 2.6 ± 0.9 *vs* 8.7 ± 1.4 % IAPP release expressed as a percentage of cellular IAPP content, p<0.01). Consistent with these results, the study of calcium signals demonstrated an absence of response to glucose in hIAPP cells. Whereas 76,61% of control cells (194/201) exhibited a normal response to 16.7mM glucose, none of the hIAPP cells tested were able to respond to glucose (0/192). hIAPP cells showed an oxygen consumption higher than control cells which is likely due to an increase in uncoupled respiration (25.8 ± 2.2 vs 15.6 ± 2.5 pmol/s/million of cells, p<0.05). Moreover, hIAPP cells exhibited a significantly increased mitochondrial membrane potential relative to control cells which is represented by a greater decrease of probe fluorescence in response to glucose stimulation (64.02 ±1.45 vs 79.57 ± 1.73 % leftover fluorescence relative to 2.2 mM glucose, p<0.05). In addition, hIAPP cells cultured in 16.7 mM glucose for 24h had significantly elevated ROS levels compared to control cells cultured in the same conditions (1.37 ± 0.1 vs. 1.01 ± 0.02 fold over 2.2 mM glucose, p<0.01).
Conclusion: Our preliminary results show that hIAPP overexpression decreased glucose stimulated insulin and IAPP secretion. Those results could be explained by an inhibition of intracellular calcium mobilisation, an increased ROS generation in response to glucose, and an altered mitochondrial function.

Mimitin overexpression protects insulin-producing INS1E cells against cytokine-induced apoptosis via prevention of MAP1S action

K. Hanzelka, S. Lenzen, E. Gurgul-Convey;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and aims: Mimitin is a mitochondrial protein, which was shown to be induced by cytokines in insulin-producing cells. It has been reported that in some cell types it can interact with a partner protein called MAP1S. MAP1S is a microtubule associated protein, which triggers a cytoplasmic signal for apoptosis, mainly via induction of ER stress. The aim of this study was to investigate the possible interaction of these two proteins in insulin-producing cells and the influence of mimitin overexpression on cytokine-stimulated apoptotic pathways.
Materials and methods: Insulin-producing INS1E cells and INS1E-hMim cells (overexpressing mimitin) were used. The cells were treated with IL-1 beta 600 U/ml or with a cytokine mixture (60 U/ml IL-1 beta, 175 U/ml TNF-alpha and 14 U/ml IFN-gamma) for 24 h. Cell viability was estimated by MTT assay, cell proliferation by BrdU incorporation, NF-kappa B by an SEAP reporter gene assay, nitrite accumulation was determined by the Griess method and caspase activation was quantified by flow cytometry. Fluorescent microscopy was used to analyze mimitin and MAP1S expression.
Results: The analysis of mimitin and MAP1S expression using specific fluorescent probes revealed that mimitin resided in the mitochondria, while MAP1S was in the cytoplasm. Upon exposure to cytokines mimitin partially moved from mitochondria into the cytoplasm and interacted there with MAP1S. Overexpression of mimitin protected INS1E cells against cytokine toxicity and prevented deleterious effects of cytokines towards cell proliferation (MTT 24h: INS1E IL-1 beta 58%, cytokine mix 37% vs. INS1E-hMimitin IL-1 beta 84 %, cytokine mix 57%; proliferation rate after 24h: INS1E IL-1 beta 58%, cytokine mix 28% vs. INS1E-hMimitin IL-1 beta 85%, cytokine mix 54%). The cytokine-induced caspase-3 activation was completely abolished in INS1E-hMim cells (24 h, INS1E: IL-1 beta 156 ± 16, cytokine mix 165 ± 19; INS1E-hMim: IL-1 beta 110 ± 11, cytokine mix 88 ± 10). The mitochondrial caspase-9 activation induced by cytokines was not affected by mimitin overexpression (24 h, INS1E: IL-1 beta 188 ± 16, cytokine mix 181 ± 16; INS1E-hMim: IL-1 beta 129 ± 5, cytokine mix 150 ± 11). Interestingly, caspase-8, triggering the extrinsic apoptotic pathway and caspase-12, associated with the ER stress response, were both downregulated by mimitin overexpression (caspase 8 after 24 h, INS1E: IL-1 beta 187 ± 14, cytokine mix 138 ± 8; INS1E-hMim IL-1 beta 110 ± 8, cytokine mix 108 ± 8; caspase-12, INS1E: IL-1 beta 151 ± 11, cytokine mix 198 ± 17; INS1E-hMim: IL-1 beta 105 ± 10, cytokine mix 116 ± 15). No significant effect of mimitin overexpression on the NF-kappa B-iNOS pathway was observed.
Conclusion: Mimitin prevents cytokine-induced death of insulin-producing cells and stimulates cell proliferation. We hypothesize that the protective effect of mimitin against cytokine-induced apoptosis occurs via prevention of cytotoxic action of the proapoptotic protein MAP1S.

502

Expression of iNOS in pancreatic islets of human type 2 diabetic patients

A. Balhuizen, S. Muhammed, R. Kumar, A. Salehi;
Department of Clinical Sciences, Lund University, Malmö, Sweden.

Background and aims: Accumulating data suggest that nitric oxid (NO) produced by inducible NOS (iNOS) play an essential role in the β-cell dysfunction and apoptosis. The main purpose of this investigation was to clarify whether the iNOS derived NO is involved in secretory defect and β-cell dysfunction of pancreatic islets isolated from human type 2 diabetic patients is associated with exaggerated NO production through the induction of iNOS expression.
Materials and methods: iNOS expression was analyzed by confocal microscopy, Western blot and qPCR in islets from both human type 2 diabetic and non-diabetic donors. Hormone secretion was determined with RIA.
Results: Confocal microscopy revealed that iNOS is expressed in pancreatic islet cells (insulin, glucagon and somatostatin) of type 2 diabetic subjects and that no iNOS was detected in islets from normal human donors. iNOS mRNA and protein expression was markedly higher in diabetic vs normal human islets ($p<0.001$). The hormone secretory pattern of type 2 diabetic pancreatic islets incubated at different glucose concentrations showed a reduced insulin and somatostatin response to glucose. The suppressing effect of glucose on glucagon secretion was not observed in the incubated islets of type 2 diabetic subjects.
Conclusion: Our data shows that long term hyperglycemia seen in human type 2 diabetic patients, based on their HbA1c, might result in the expression of iNOS in the pancreatic islets which consequently might disrupt he normal β-cell function.

Mcl-1 degradation by pro-inflammatory cytokines and palmitate is an early and major event for beta cell apoptosis

A.K. Cardozo[1], D. Cunha[1], F. Moore[1], J. Vanderwinden[2], D.L. Eizirik[1], F. Allagnat[1];
[1]Laboratory of Experimental Medicine, [2]Laboratory of Neurophysiology, Université Libre de Bruxelles, Belgium.

Background and aims: Apoptosis of the insulin-secreting pancreatic beta cell is a key feature of diabetes mellitus and the mitochondrial pathway of apoptosis is a major mediator of beta cell death. The myeloid cell leukemia sequence 1 (Mcl-1) is an important anti-apoptotic protein of the Bcl-2 family, a group of proteins involved in the mitochondrial pathway of apoptosis. The aim of this study was to evaluate the role of Mcl-1 in beta cell apoptosis.
Materials and methods: We studied the effect of pro-inflammatory cytokines (IL-1β or TNF-α, in combination or not with IFN-γ), free fatty acids (palmitate or oleate), and chemical ER stressors (CPA, thapsigargin, tunicamycin) on Mcl-1 mRNA and protein expression in INS-1E cells, and, in selected experiments, in FACS-purified rat beta cells. Using mRNA silencing and recombinant adenoviruses, we studied the effect of Mcl-1 knockdown and overexpression on beta cell function and apoptosis. Expression of Mcl-1 and key downstream genes and proteins were measured by real time RT-PCR and/or Western blot. Localisations of Bax and cytochrome c were studied by immunofluorescence in cells overexpressing Mcl-1 and treated with cytokines, palmitate or thapsigargin. Cell viability was evaluated by HO 342 and propidium iodide.
Results: All cytotoxic stresses described above increased Mcl-1 mRNA expression by 2 fold, but rapidly and preferentially decreased Mcl-1 protein expression by 30 to 60% ($p< 0.05$). ER stress-induced Mcl-1 down-regulation was prevented upon PERK knock down and resulting inhibition of eIF2α phosphorylation, indicating that translation arrest contributes to Mcl-1 downregulation. Additionally, the effect of cytokines on Mcl-1 expression was also partially prevented in presence of a JNK inhibitory peptide. Knocking-down Mcl-1 using siRNAs increased by 40% apoptosis and caspase 3 cleavage induced by cytokines, palmitate or thapsigargin ($p<0.01$). On the other hand, Mcl-1 overexpression reduced by 50% Bax translocation to the mitochondria, cytochrome c release, caspase 3 cleavage and apoptosis induced by the beta cell death effectors ($P< 0.01$). Neither Mcl-1 knockdown nor overexpression modified basal or glucose-stimulated insulin secretion.
Conclusion: The present data suggest that Mcl-1 downregulation is a crucial event leading to beta cell apoptosis and provide new insights in the mechanisms linking ER stress and the mitochondrial intrinsic pathway of apoptosis. Mcl-1 is therefore an attractive target for the design of new strategies in the treatment of diabetes.

Background and aims: The study of the effects of diabetogenic factors on the pancreatic α-cell are relatively limited when compared to its neighbour, the pancreatic β-cell. In recent years the regulation of glucagon secretion has attracted considerable attention from molecular bioscientists. The dysregulation of glucagon secretion in both type 1 and type 2 diabetes mellitus is of physiologic and pathologic importance as little has been achieved in relation

to counteracting the dysregulation of glucagon secretion in diabetes. The effects of proinflammatory cytokines on the β-cell are well documented but little has been reported on the mechanisms of cytokine induced α-cell dysregulation. IL-1β, TNF-α and IFN-γ are commonly used for initiation of dysfunction and death in the pancreatic β-cell. This investigation has determined the effects of these cytokines on the pancreatic α-cell under various incubation conditions relating to the availability of islet cell secretory products.
Materials and methods: The clonal cell line α-TC1-9 were seeded in 6 well plates under various conditions in relation to proinflammatory cytokine levels, Zn^{2+} levels, Insulin Levels and glucose levels for various time points. Metabolite consumption, Glutathione ratio and ATP levels were assessed using enzymatic methods, glucagon levels were assessed using HTRF techniques and Ca^{2+} fluctuations were assessed using flow cytometry.
Results: Addition of various concentrations of the cocktail of proinflammatory cytokines to the αTC1-9 cell line (various dilutions of the following: 5U/ml IL-1β, 1000U/ml TNF-α and 500U/ml IFN-γ) resulted in a dose dependent increase in glucagon secretion, up 327% compared to basal levels (n=6). Intracellular levels of reduced glutathione were increased by 1.2 fold, while intracellular levels of oxidised glutathione were not increased significantly in any condition. Glucose and Glutamine consumption was also increased, dose dependently, with increases in proinflammatory cytokine cocktail concentration. Glucagon secretion was reduced by addition of Zn^{2+} and/or insulin an effect partly attenuated (34.3-69.4%) by addition of various concentrations of glucose (0-25mM). This inhibitory effect was lost in a dose dependent fashion with the addition of the proinflammatory cytokine cocktail.
Conclusion: Proinflammatory cytokines had a dose dependent effect on metabolite consumption including glucose, glutamine etc. and glucagon secretion from α-TC1-9 cells. Glucose was able to partly attenuate the negative effect of the cytokines.

Toll-like receptor 4 in islets of Langerhans - a potential role in beta cell death in type 2 diabetes
M. Ladefoged, A.M. Hansen;
Novo Nordisk A/S, Måløv, Denmark.

Background and aims: Type 2 diabetes is a characterised by insulin resistance, beta-cell dysfunction and increased systemic levels of free fatty acids (FFA). Furthermore, it is recently becoming clear that activation of the innate immune system via toll-like receptors (TLRs), in particular TLR2 and TLR4, is implicated in the pathogenesis of insulin resistance and type 2 diabetes. Activation of TLR4 by ligands of both exogenous and endogenous origin (e.g. LPS, FFA) causes an initiation of intracellular pro-inflammatory signalling pathways and a subsequent release of pro-inflammatory mediators such as TNFα, IL-1 and IL-6. Most cells in the body, including immune and insulin-sensitive cells, have a low basic expression of TLR4 under normal conditions. In obese and type 2 diabetic patients the level of the TLR4 ligands LPS and FFA are elevated, and recent studies demonstrate a resulting increase in TLR4 expression in macrophages, adipocytes and muscle cells suggesting a link between TLR4 expression and development of insulin resistance. In addition to insulin resistance, type 2 diabetes is characterised by beta-cell dysfunction. Recent studies report increased infiltration of macrophages in islets of Langerhans from patients with type 2 diabetes and in a variety of type 2 diabetic animal models, raising the possibility that TLR4 expression and a resulting cytokine release might be increased in islets under diabetic conditions. TLR4 expression has been described in pancreatic islets under normal conditions; however changes in the expression pattern have not yet been investigated with respect to diabetes development. Our hypothesis is that TLR4 expression and signalling is increased in islets of Langerhans in obesity and the resulting increase in secretion of cytokines causes beta-cell dysfunction and manifestation of diabetes. We investigate the hypothesis in the db/db mouse - an animal model of type 2 diabetes.
Materials and methods: Islets of Langerhans from male db/db (4, 8 and 15 weeks old, representing diabetes progression with age) as well as control db/+ (15 weeks old) mice were isolated using collagenase digestion. RNA was extracted and changes in gene expression of Toll-like pathway products (TLR4, TLR2, MyD88, NFκB) and selected cytokines (TNFα, IL-1α, IL-1β, IL-6, IP-10, IFNγ) during development of diabetes examined using real-time PCR. Additionally, secretion over a 24h period of the above mentioned cytokines from islets was quantified (Milliplex).
Results: TLR4 mRNA was found in islets from both lean and obese mice with a 7.4 ± 1.6 fold higher level in islets from obese diabetic 15 weeks old db/db compared to 15 weeks old db/+ mice ($p<0.01$) ($n\geq3$). TLR4 gene expression increased with progression of diabetes in db/db mice showing a 5.6 fold higher level of TLR4 mRNA in islets from 15 weeks old db/db compared to islets from 4 weeks old db/db mice ($p<0.01$) ($n\geq3$). Furthermore, both protein and gene levels of all cytokines examined, except IFNγ, increased significantly in islets during development of type 2 diabetes in db/db mice. No significant differences were observed for IFNγ.
Conclusion: Expression of TLR4 and its intracellular signalling molecules in db/db mouse islets were increased in parallel with diabetes development. Also, expression and secretion of cytokines and chemokines were found significantly increased in diabetic vs. non-diabetic mouse islets. Our results support the hypothesis that, in addition to its contribution to insulin resistance, TLR4 may also be a causative factor in beta-cell death leading to type 2 diabetes.

Regulation of beta cell survival and function by 14-3-3 proteins
G.E. Lim, J.D. Johnson;
Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

Background and aims: Diabetes is associated with increases and decreases in pancreatic beta cell death and function. Numerous factors promote cell survival through the activation of survival kinases and deactivation of pro-apoptotic proteins. Previously, we have demonstrated that insulin promotes beta cell survival and proliferation via Raf-1 kinase. The importance of Raf-1 as a regulator of survival was further elucidated by pharmacological inhibition of Raf-1, which induced cell death. In other cell types, scaffold proteins of the 14-3-3 family regulate Raf-1 and other growth factor signaling cascades, but their function in beta cells is unknown. We, therefore, hypothesize that 14-3-3 proteins regulate beta cell function and survival.
Materials and methods: The MIN6 beta cell line and primary mouse islets were used to assess the role of 14-3-3 proteins on cell function and survival by overexpression of proteins and shRNA. Quantitative PCR (qPCR) was performed to measure mRNA levels. Fluorescent microscopy was used to visualize protein localization as well to quantify cell death. Western blots and co-immunoprecipitation were used to detect protein interactions, phosphorylation, and expression. Insulin was measured by ELISA.
Results: Of the 7 isoforms, 14-3-3 ζ, η, θ transcripts levels were expressed at the highest levels, followed by γ, β, ε, and σ in MIN6 cells and mouse islets. Fluorescent microscopy showed that 14-3-3 ζ was localized to beta cells, endothelial cells, but not exocrine tissue in the mouse pancreas. In isolated primary beta cells, 14-3-3 ζ was predominantly cytoplasmic, and co-localization with insulin granules was also observed. To analyze the function of 14-3-3 proteins, difopein-EYFP, a pan 14-3-3 inhibitor, was expressed in MIN6 cells. Inhibition caused a 3.8-fold increase ($p<0.05$) in propidium iodide-positive cells, a marker of cell death and a 1.5-fold increase ($p<0.05$) in cleaved caspase-3, a marker of apoptosis. Moreover, there was a 1.3-fold increase ($p<0.05$) in basal insulin release. As several studies have shown that 14-3-3 ζ regulates cell survival, MIN6 cells were transfected with wild-type (WT) 14-3-3 ζ or control plasmids. Treatment with cytokines (25ng/ml TNF-α, 10ng/ml IL-1β, and 10mg/ml IFN-γ) induced a 2.5-fold increase in cell death ($p<0.05$), which was completely prevented by WT-14-3-3 ζ over-expression. Similarly, cell death stimulated by 1μM thapsigargin was reduced by 43% ($p<0.05$). Transfection of MIN6 cells with shRNAs against 14-3-3 ζ led to a 1.4-fold increase ($p<0.05$) in cleaved caspase-3 levels. Dissociation of Raf-1 from 14-3-3 ζ is required for its activation, and treatment of MIN6 cells with a picomolar concentration of insulin decreased by 63% ($p<0.05$) the amount of Raf-1 that complexed with 14-3-3 ζ. The decrease in 14-3-3 ζ: Raf-1 association was mirrored by an increase in 14-3-3 ζ association with Bad, a proapoptotic protein. Static cultures on MIN6 cells were used to assess the effect of WT-14-3-3 ζ or shRNAs on insulin secretion. Overexpression of WT-14-3-3 ζ induced an 8.5-fold increase in basal insulin secretion from MIN6 cells. Conversely, shRNA-mediated knockdown of 14-3-3 ζ decreased basal and glucose-induced insulin secretion.
Conclusion: The present study demonstrates for the first time that 14-3-3 proteins regulate beta cell survival and function. Alterations in the expression of 14-3-3 proteins may represent a novel therapeutic approach to modulate insulin signaling and promote beta cell survival and function.

Expression of salivary type amylase in human pancreatic beta cells and its induction by pro-inflammatory cytokines in MIN6 beta cells

S. Arai-Yamashita[1], H. Shimura[2], K. Aida[2], S. Takizawa[2], M. Takahashi[2], M. Aoyagi[2], S. Tanaka[2], T. Endo[2], T. Kobayashi[2];
[1]Department of Clinical Science, Lund University/CRC, Malmö, Sweden,
[2]Third Department of Internal Medicine, University of Yamanashi, Japan.

Background and aims: Autoantibodies against amylase (AMY) were detected at a high frequency in sera from patients with diabetes associated with autoimmune pancreatitis (DAIP) or with fulminant type 1 diabetes (FT1DM). The possible relationship between beta-cell destruction and autoimmunity against AMY is not clear. The aim of this study was to examine AMY expression in 1) the pancreatic islet-cells of autopsied patients with FT1DM and 2) mouse MIN6 beta cells exposed to Th1 cytokines.
Materials and methods: AMY expression in islet beta cells from three FT1DM patients dead 2-5 days after the onset and three non-diabetic control pancreas were analyzed by immunohistochemical staining with AMY1 (salivary type) -specific monoclonal and AMY2 (pancreatic) -specific monoclonal antibodies. Quantitative RT PCR was used to detect the expression of both AMY1 and AMY2 (pancreatic type) in MIN6 beta cells incubated with Th1 cytokines. The MIN6 cells were also subjected to immunohistochemical staining using monoclonal AMY1 antibodies.
Results: Severe mononuclear cells infiltration (insulitis) was observed in islets of FT1DM patients but not the islets of control non-diabetic subjects. An AMY1, but not AMY2, monoclonal antibody identified immunoreactivity of AMY in beta cells, but not alpha or exocrine acinar cells, of non-diabetic human. The AMY1 staining was also observed in the islets from FT1DM patients. Western blotting revealed that serum from patients with autoimmune pancreatitis had IgG detecting AMY1. AMY1 mRNA levels in MIN6 beta cells were 108-fold higher than AMY2. MIN6 beta cells cultured with either IFN-γ or TNF-α alone did not affect AMY1 expression. In contrast, simultaneous addition of IFN-γ and TNF-α induced a synergistic 5-fold increase of AMY1 but not AMY2 levels. The MIN6 beta cells cultured simultaneously with IFN-γ and TNF-α showed an increased AMY immunoreactivity compared to the cells treated with IFN-γ or TNF-α alone.
Conclusion: We conclude that human pancreatic islet beta-cells express AMY1 and its expression was also observed in islets from FT1DM patients. Infiltrating mononuclear cells in FT1DM or DAIP are known to produce Th1 cytokines. It was of interest that the expression of AMY1 gene in pancreatic MIN6 beta-cells was enhanced synergistically by Th1 cytokines. This observation suggests that islet beta-cells hyper-expressing AMYI may be the target for beta-cell autoimmunity in DAIP and FT1DM.

Siglecs are differentially expressed in pancreatic islets and regulate beta cell function and survival

G. Dharmadhikari[1], F. Paroni[1], J. Kerr-Conte[2], S. Kelm[1], K. Maedler[1];
[1]Centre for Biomolecular Interactions, University of Bremen, Germany,
[2]Thérapie Cellulaire du Diabète, INSERM /Université de Lille, France.

Background and aims: In both type 1 diabetes mellitus (T1DM) and type 2 diabetes mellitus (T2DM), local inflammation and cytokine and chemokine production within pancreatic islets has been observed and is detrimental for the β-cell. Siglecs (Sialic-acid binding immunoglobulin like lectins) are cell surface receptors expressed on haematopoietic cells which participate in immune responses. Their prominent position, negative charge and widespread distribution make sialic acids an important component in cell-cell interactions as well as pathogen and toxin binding. Our investigations revealed a cell-type specific expression of Siglecs in pancreatic islets, which is altered in diabetic conditions, hinting towards their role in survival and function of these pancreatic cells.
Materials and methods: The expression of Siglecs 3, 5, 6, 7, 8 and 10 in pancreatic sections was analyzed by immunofluorescence in pancreatic sections from autopsy from patients with T2DM and controls as well as in isolated human islets exposed to a diabetic milieu (increasing glucose (11.1-33.3 mM), 2 ng/ml IL-1β alone or in combination with 1,000 U/ml IFN-γ, 100 ng/ml LPS, 0.5 mM palmitate, 50 μg/ml synthetic ds RNA analogue Poly:IC or 50 μM H_2O_2). The siglecs cellular localization was confirmed by Confocal Laser scanning microscopy. Siglec expression was evaluated by quantitative real time PCR of cDNA from human pancreases from autopsy. To investigate its role in β-cell function, Siglec 7 over-expression by plasmid transfection was carried out followed by glucose stimulated insulin secretion (GSIS).
Results: Triple staining for Siglecs 3, 5, 6, 7, 8 and 10; glucagon and insulin in pancreatic sections of healthy controls and patients with T2DM showed cell type specific siglec expression in the human pancreas: Siglecs 3, 5 and 8 were expressed in the glucagon producing α-cells, Siglecs 7 and 10 were expressed in the insulin producing β-cells and Siglec 6 was expressed in the exocrine pancreas. Siglec expression was not uniform in the cells but was aggregated at certain locations; this was observed independently from diabetes. This expression pattern hints towards a cell-cell interaction junction which is facilitated by these siglecs. A diabetic milieu had an inductive effect on siglec expression in those cells in human islets *in vitro* and *in vivo*. Real time PCR analysis revealed that siglecs expressed in α-cells Siglec-3,-5 and -8 showed a 5.9-fold, 7.9-fold and 6.1-fold increase in its expression in patients with T2DM as compared to the non diabetic controls. In contrast, in the siglecs expressed in the β-cells, there was an 85% decreased expression in siglec 7 and a 47% decrease in siglec 10 expression in patients with T2DM. Since Siglec 7 was markedly downregulated in T2DM in poorly functional β-cells, we wanted to know if over-expression of siglec 7 has an opposite effect on β-cell function. Indeed, plasmid over-expression of Siglec 7 increased GSIS 1.5-fold in human islets and prevented glucose and palmitate induced apoptosis, when compared to the lacZ transfected control islets.
Conclusion: Our data suggest that Siglecs are differentially expressed in pancreatic islets, are regulated in T2DM and influence β-cell function and survival. Siglecs could play an important role not only in the crosstalk of β-, α- and immune cells but also in maintaining glucose homeostasis.

MST1 mediates beta cell apoptosis and impaired function

A. Ardestani[1], F. Paroni[1], J. Kerr-Conte[2], K. Maedler[1];
[1]Centre for Biomolecular Interactions, University of Bremen, Germany,
[2]Thérapie Cellulaire du Diabète, INSERM /Université de Lille, France.

Background and aims: Pancreatic β-cell death is the fundamental cause of type 1 and type 2 diabetes (T2DM). Mammalian sterile 20-like kinase 1 (MST1) is a serine threonine kinase, which mediates apoptosis in response to cytotoxic stress. MST1 is both, cleaved and activated by caspases, and also serves as an activator of caspases to amplify the apoptotic signaling pathways. In the present study, we investigated the possible patho-physiological activation of MST1 in β-cells under diabetic conditions, which may be a major common pathway of β-cell death in diabetes.
Materials and methods: Isolated human islets and the human β-cell line CM9 were exposed to a diabetic milieu (cytokine mixture IL-1β/IFNγ, oxidative stress (H_2O_2) or increasing glucose concentrations). Phospho-MST1 and MST1 cleavage, Phospho-JNK, Phospho-Histone2B (direct cellular substrate of MST1) and β-cell apoptosis (cleaved Caspase 3 & PARP) were analyzed by western blotting. MST1 or dominant-negative MST1 were overexpressed by plasmid transfection into human islets and CM9 cells and its direct effect on β-cell apoptosis (TUNEL assay & caspase 3 activation) and function (GSIS, PDX1 localization) analyzed. MST1 activation was investigated in isolated islets from a patient with T2DM and from an animal model of T2DM, the high fat/ high sucrose diet fed mouse (HFD).
Results: MST1 cleavage & phosphorylation was increased in human islets and CM9 cells exposed to IL-1β/IFNγ mixture, H_2O_2 or increasing glucose concentrations (11.1-33.3 mM). This correlated with increased P-H2B, P-JNK and apoptosis. We found the JNK pathway as a mediator of MST1-induced apoptosis, because JNK inhibition (by JNK inhibitor SP600125) diminished caspase-mediated MST1 cleavage and apoptosis. In isolated islets from patients with T2DM as well as from HFD mice, MST1 activation was increased and correlated with JNK activation and apoptosis. Inhibition of endogenous MST1 activity by overexpression of dominant negative MST1 inhibited apoptosis induced by a diabetic milieu. In contrast, overexpression of MST1 increased β-cell apoptosis 4-fold (P>0,05) and reduced glucose stimulated insulin secretion 1.6-fold (p>0,05), indicating that MST1 alone is sufficient to promotes β-cell failure. By an in vitro kinase assay using recombinant MST1 and PDX-1 as substrate we found that MST1 phosphorylates PDX-1. In line with this MST1 overexpression induced PDX-1 shuttling from the nucleus to the cytosol, providing an explanation for the impaired insulin secretion.
Conclusion: Our results suggest that MST1 is a critical mediator of impaired β-cell function and apoptosis. Inhibiting the MST1-pathway could be an important strategy to prevent β-cell apoptosis.
Keywords: Mammalian sterile 20-like kinase 1 (MST1), apoptosis, diabetes, β-cell, c-Jun N-terminal kinase (JNK) and Pancreatic Duodenal Homeobox-1 (PDX-1).

Islet human amylin oligomer formation is differentially correlated with beta cell death and diabetes onset between homozygous and hemizygous human amylin transgenic mice

S. Zhang, H. Liu, X. Li, M. Au, C.-L. Chuang, G.J.S. Cooper;
School of Biological Sciences, University of Auckland, New Zealand.

Background and aims: One of the pathological features of type-2 diabetes mellitus (T2DM) is the presence of islet amyloid deposits comprising mainly human amylin (hA)/hIAPP. Recent studies suggested that soluble oligomers of human amylin may be the primary cause of β-cell damage and thus contribute to the onset/development of T2DM. However, the molecular basis of this process remains to be fully elucidated. We aimed to investigate the connection between soluble oligomers and hA cytotoxicity, and their correlation with diabetes development using a rodent model of diabetes.
Materials and methods: We performed a comparative phenotypic analysis of homozygous and hemizygous hA transgenic mice for hA in their islet β-cells. Oligomer formation was studied by detection of amylin oligomer-like immunoreactive material (AOLIM) with specific anti-oligomer antibodies using immunofluorescence techniques. A co-localization study of oligomerization was carried out wherein islet cell hormones were detected by multi-labelled immunofluorescence. Apoptosis was assessed by active-caspase-3 staining.
Results: Both homozygous and hemizygous hA transgenic mice developed spontaneous diabetes associated with different elevations in hA levels and with different time frames of disease onset and death. Abnormal β-cell function and apoptosis were detected before early onset of hyperglycaemia in homozygous animals, while β-cell function (insulin secretion) remained normal till late diabetes onset in hemizygous mice. Interestingly, intracellular and extracellular AOLIM was clearly detectable before onset of diabetes in all transgenic animals with strong correlation with β-cell death in homozygous mice. However, there was no correlation between the appearance of AOLIM and the time of cell death occurring in hemizygous mice, implying a difference in the size and/or the extent of cytotoxic oligomerization in these animals. We also found that rapid β-cell depletion occurs soon after appearance of cytotoxic oligomers and onset of diabetes in homozygous animals whereas apoptosis developed slowly after the later onset of diabetes in hemizygous animals, which exhibited significant β-cell loss in a much later time frame.
Conclusion: The difference in time at which oligomerization occurs in relation to cell death and diabetes onset between homozygous and hemizygous hA-transgenic mice may suggest a dose-dependent cytotoxic effect of hA oligomers. The findings from this study will provide new insights on the cellular fate of oligomers and further enhance our understanding of amyloidosis and T2DM.

Dual effect of advanced glycation end products in pancreatic islet apoptosis and the protective role of benfotiamine and MitoQ

M. Correa-Giannella[1], F.L. Costal[1], E.R. Oliveira[1], A.R. Amaral[1], A.M.S. Lima[2], M. Passarelli[2], D. Giannella-Neto[3];
[1]Endocrinology - LIM25, [2]Endocrinology - LIM10, [3]Gastroenterology - LIM07, University of Sao Paulo Medical School, Brazil.

Background and aims: Loss of beta cell function hastens the deterioration of metabolic control in people with type 2 diabetes. Besides lipo- and glucotoxicity, advanced glycation end products (AGEs) seem to contribute to this process by promoting islet apoptosis. In other tissues, AGEs interact with their specific receptors (RAGEs) and elicit reactive oxygen species (ROS) generation and NF-kB activation. In order to investigate the temporal effect of AGEs on islet apoptosis as well as the potential of antioxidant compounds to decrease islet damage caused by AGEs,
Materials and methods: Rat pancreatic islets were treated for 24, 48, 72 and 96 h with either AGEs generated from co-incubation of bovine serum albumin (BSA) with D-glyceraldhyde (GAD, 5 mg/mL) or BSA (5 mg/mL, control). Apoptosis was evaluated by quantification of DNA fragmentation (ELISA), caspase-3 enzyme activity and detection of mitochondrial permeability transition (MitoProbe JC-1). The expression of the genes *Bax*, *Bcl2* and *Nfkb1* was evaluated by RT-qPCR. In the time points at which increased apoptosis was detected, the effect of two antioxidant compounds was evaluated: benfotiamine (350 μM), a liposoluble vitamin B1, and Mito Q (1 μM), a derivative of ubiquinone targeted to mitochondria
Results: In 24 and 48 h, AGEs elicited a significant decrease in the apoptosis rate in comparison to the control condition concomitantly with a significant increase in the RNA expression of the antiapoptotic gene *Bcl2* and a significant decrease in the *Nfkb1* RNA expression. In contrast, after 72 and 96 h, AGEs promoted a significant increase in the apoptosis rate in comparison to the control condition concomitantly with a significant decrease in *Bcl2* RNA expression and a significant increase in *Nfkb1* RNA expression. Benfotiamine and Mito Q were able to decrease the apoptosis rate of islets exposed to AGEs for 72 and 96 h.
Conclusion: AGEs exerted a dual effect in cultured pancreatic islets, being protective against apoptosis after short exposition but proapoptotic after prolonged exposition. Mito Q and benfotiamine deserve further evaluation as drugs that could offer islet protection in conditions of chronic hyperglycemia.

Galectin-3 deficiency reduces immune-mediated beta cell destruction *in vitro*

S. Stošić-Grujičić[1], T. Cvjetićanin[1], G. Timotijevic[2], N. Zdravkovic[3], M. Lukic[3];
[1]Immunology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, [2]Institute for Molecular Genetics and Genetic Engineering, University of Belgrade, [3]Center for Molecular Medicine, Faculty of Medicine, University of Kragujevac, Serbia.

Background and aims: Galectin-3 (Gal-3), a multifunctional beta-galactoside binding lectin, affects numerous biological processes and is implicated in the pathogenesis of several inflammatory/autoimmune disorders. It has been shown that Gal-3 may increase inflammatory responses through its function in cell activation, cell migration, or inhibition of apoptosis. We have recently reported that Gal-3-deficient (Gal-3$^{-/-}$) mice are relatively resistant to diabetogenesis induced by multiple low doses of streptozotocin. Little is known however, about the relevance and influence of the endogenous Gal-3 at the level of target tissue (pancreatic islets). It is established that, in Type 1 as well as in Type 2 diabetes, beta-cell function and viability are progressively disturbed through a complex process of inflammation. In addition, hyperlipidemia and inflammation, when acting in concert, may carry out a powerful attack upon pancreatic beta cells. In this context, our aim was to analyze the possible role of endogenous Gal-3 in beta cell survival and death pathways following *in vitro* treatment with cytokines and one of the most common free fatty acid -palimitic acid.
Materials and methods: Pancreatic islets isolated from C57BL/6 mice or Gal-3-null mice were incubated with palmitate and/or concanavalin A-stimulated spleen-cell culture supernatant containing soluble immune cell products. Alternatively, the cooperative effect of culture supernatant components was mimicked with the combination of recombinant cytokines (IL-1β+TNF-α+IFN-γ). After incubation, beta cell apoptosis was determined by MTT test, or histone-DNA ELISA. Expression profiles of various related genes were determined at mRNA and protein levels by real time PCR, and Western blot, respectively.
Results: Targeted disruption of *Gal-3* gene attenuated palmitate-induced beta cell lipotoxicity. Moreover, Gal-3$^{-/-}$ pancreatic islets were more resistant than wild type counterparts to cytokine induced apoptosis. The transcription of anti-apoptotic Bcl-2 was up-regulated in Gal-3$^{-/-}$ islets only, whereas in wild type islets it was down-regulated. Although Bcl-xL mRNA was up-regulated in both groups of islets, the increase was more pronounced in Gal-3$^{-/-}$ islets. In contrast, the transcription of pro-apoptotic Bid was down-regulated in Gal-3$^{-/-}$ islets only. Interestingly, basal levels of anti-apoptotic proteins were higher in Gal-3$^{-/-}$ islets than in wild type islets, further suggesting favouring of cell protective over pro-apoptotic molecules in molecular regulation of Gal-3$^{-/-}$ beta cell survival.
Conclusion: Our findings clearly show that the absence of Gal-3 confers beta cell protection from the lethal insult of different agents, namely cytokines and saturated free fatty acids. This protection is probably mediated by differential regulation of pro- and anti-apoptotic molecules within the beta cells. The study thus provides *in vitro* evidence for a critical role of Gal-3 in destruction at the level of pancreatic islets and suggests a new therapeutic strategy for the treatment of diabetes based on the selective inhibition of Gal-3 activity.

Ectopic overexpression of acute stress protein p8 reduces streptozotocin (STZ)-induced apoptosis in INS-1E (STZ) beta cells

G. Päth, E. Tsaroucha, I. Pilz, P.J. Feilen, S. Ehler, M. Alt, B. Dufner, J. Seufert;
Endocrinology / Diabetology - Labor B9, University Hospital Freiburg, Germany.

Background and aims: Protein p8 is associated with proliferation and tissue protection. p8 knock out animals display enhanced lethality after LPS treatment and enhanced pancreatitis-induced tissue damage in the exocrine pancreas. Within the endocrine pancreas own previous work characterised p8 as a glucose-dependent mediator of beta cell proliferation. Here we investigate the cell protective properties of p8 in response to STZ treatment in INS-1E beta cells.
Methods and results: Exposure of native INS-1E to STZ strongly upregulates activity of the apoptosis effector molecules caspases 3 and 7 (Chemiluminescence assay) resulting in cell death with a 24 h LD50 of 0.66 mM STZ (MTS). In parallel, 0.66 mM STZ acutely induces endogenous p8 gene expression (qPCR), which peaks after 6 h and fastly declines to vehicle control levels after 12 h. STZ-induced p8 gene expression (6 h) was further strictly dose-dependent up to 1 mM STZ and gets saturated at 3.3 mM. To investigate effects of high p8 levels on viability and apoptosis, we generated INS-1E beta cells with stable p8 overexpression under the control of a CMV promoter (p8-INS1) and empty plasmid control cells (mock-INS1). Under basal conditions, p8-INS1 cells as compared to mock controls demonstrate substantially enhanced viability resulting in significantly increased cell numbers after 5 days in culture. Also under tissue stress conditions, viability of p8-INS1 was substantially enhanced if exposed to 0.33 to 3.3 mM STZ for 24 h. These findings correspond to significantly lowered (about 60%) 0.33 to 1 mM STZ-induced activation of caspases 3 and 7 after 8 h.
Conclusion: These results demonstrate that, in beta cells, p8 is acutely induced by tissue stress and mediates enhanced viability and proliferation and reduces STZ-induced apoptotic cell death.

Paracrine signaling loops in adult pancreatic islets: Netrins modulate beta cell apoptosis via Neogenin and Unc5a

Y.H.C. Yang[1], B.G. Hoffman[2], M. Szabat[1], C. Bragagnini[1], K. Kott[1], C.D. Helgason[3], J.D. Johnson[1];
[1]Department of Cellular and Physiological Sciences, Department of Surgery, University of British Columbia, Vancouver, [2]Child & Family Research Institute, Department of Surgery, University of British Columbia, Vancouver, [3]Department of Cancer Endocrinology, BC Cancer Research Center, Vancouver, Canada.

Background and aims: Adult pancreatic islets contain multiple cell types that produce and secrete well characterized hormones including insulin, glucagon and somatostatin. Although it is becoming increasingly apparent that islets release and respond to more secreted factors than previously thought, systematic analyses are lacking. The aims of the present study were to identify potential autocrine/paracrine islet growth factor loops and to characterize the function of a family of previously unreported islet secreted factors and their receptors.
Materials and methods: Gene expression databases, islet specific SAGE and Tag-Seq libraries, and microarray datasets of FACS purified human beta-cells were used to compile a list of secreted factors and secreted factor receptors present in mouse or human islets. The presence of Netrins and their cognate receptors were assessed using RT-PCR, western blot analysis, and immnofluorescence staining. The roles of Netrin-1 and Netrin-4 in beta-cell function, apoptosis, and proliferation were also examined.
Results: A list of 230 secreted factors and 238 secreted factor receptors (189 factor-receptor pairs) were found in islets. This genome-wide analysis led us to characterize the role of netrins in adult pancreatic beta-cell apoptosis. The presence of netrins and their cognate receptors (Neogenin, DCC, and Unc5A-D) were confirmed using RT-PCR, western blot analysis, and immnofluorescence staining. Down-regulation of caspase-3 activation was observed when MIN6 cells were exposed to exogenous Netrin-1 and Netrin-4 under hyperglycaemic conditions, and the observed effects were not dependent on induction of insulin secretion. Reduction in caspase-3 cleavage was linked to the decrease in dependence receptors, Neogenin and Unc5A.
Conclusion: Together, our results highlight the large number of potential islet growth factors and point to a context-dependent pro-survival role for netrins in the adult pancreatic beta-cells. Since diabetes results from a deficiency in functional beta-cell mass, these studies are an important step towards developing novel therapies to improve beta-cell survival.

The fibrosis in pancreatic islets at an early stage of life involves in diabetes development in obese diabetic db/db mice

Y. Kanda, S. Hamamoto, M. Shimoda, K. Tawaramoto, M. Hashiramoto, K. Kaku;
Diabetes and Endocrine Division, Kawasaki Medical School, Kurashiki-shi, Japan.

Background and aims: The *db/db* mice develop diabetes with severe insulin resistance and limited capacity of insulin secretion. On the other hand, the

ob/ob mice with a similar genetic background do not present diabetic manifestation because of a compensatory hypersecretion of insulin. We previously reported that the *ob* gene, but not *db* gene, homozygote acquires a compensatory mechanism of beta cell protection probably through anti-oxidative stress mechanism at 12 weeks of age. In this study, to further investigate the molecular mechanism of diabetes development in *db/db* mice, the beta cell function and gene expression profiles specific for pancreatic islets in *db/db* mice were compared with those in *ob/ob* mice at an early stage of life, when metabolic parameters were not different between two strains of mice.
Materials and methods: Body weight (BW), fasted blood glucose (FBG), fasted insulin (FIRI), TG and FFA in *db/db*, *ob/ob* and lean littermates *m/m* mice were measured at 6 weeks of age. The beta cell mass and cell ratio were assessed by histological analysis of the islet tissue. In the first step of molecular analysis, we examined comprehensive gene expression profiles of isolated islets by the cDNA microarray analysis. Furthermore, gene expressions specific for the core area of pancreatic islet were analyzed by Laser Capture Microdissection (LCM) method and real time RT-PCR. Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, apoptosis, cell cycle, and oxidative stress were prepared, and real-time RT-PCR with Sybr Green was applied at 6 week old mice.
Results: BW in *db/db* mice was significantly greater than that in *m/m* mice, but was lower than *ob/ob* mice. FBG and FIRI in *db/db* and *ob/ob* mice were significantly higher than those in *m/m* mice, but no difference was observed between *db/db* and *ob/ob* mice (FBG: 93.1±6.0 in *db/db*, 89.9±5.8 in *ob/ob*, 53.6±3.6 mg/dl in *m/m*, FIRI: 1.84±0.10, 1.58±0.12, 0.12±0.01 ng/ml at 6 weeks of age, $p<0.05$, respectively). TG and FFA levels in *db/db* and *ob/ob* mice were significantly higher than those in *m/m* mice. The beta cell mass and cell ratio in *db/db* was significantly less than those in *ob/ob* and *m/m* mice at 6 weeks of age (cell mass: 1.03±0.04 in *db/db*, 1.16±0.02 in *ob/ob*, 1.12±0.06 mg in *m/m*, and cell ratio: 81.1±0.1, 83.0±0.5, 82.9±0.4%, respectively). The cDNA microarray analysis at 6 weeks of age demonstrated no significant difference in the islet gene expressions related with cell differentiation/proliferation and ER/oxidative stress among three groups. On the other hand, the tissue fibrosis and inflammation related genes were highly expressed in *db/db* mice than in *ob/ob* mice. The LCM and real-time PCR analysis revealed a significant increase in insulinIIgene expression in both *db/db* and *ob/ob* mice. Nkx6.1 gene related with cell differentiation was significantly increased in *ob/ob* compared with *db/db* and *m/m* mice. The cell proliferation, cell apoptosis and ER/oxidative related gene expressions were not different among three groups of mice. On the other hand, fibronectin and collagen type 1 gene expressions were significantly up-regulated in *db/db* mice compared with *ob/ob* and *m/m* mice.
Conclusion: The present results suggest that the preceding tissue fibrosis in pancreatic islets at an early stage of life may be involved in diabetes development in *db/db* mice.

A lipidomic screen of lipotoxic pancreatic beta cells reveals links between ceramide accumulation in the endoplasmic reticulum (ER), impaired protein trafficking, ER stress and apoptosis

E. Boslem[1], A.M. Preston[1], M. Fuller[2], D.R. Laybutt[1], P.J. Meikle[3], T.J. Biden[1];
[1]Diabetes and Obesity, Garvan Institute of Medical Research, Sydney, [2]Children, Youth and Women's Health Service, Adelaide, [3]Baker IDI Heart Research Institute, Melbourne, Australia.

Background and aims: An intrinsic effect of saturated fatty acids (FAs) on the pancreatic β-cell contributes to the β-cell death that occurs in Type 2 diabetes. The exact mechanism by which saturated FAs bring this about remains elusive, but is mediated, in part, by endoplasmic reticulum (ER) stress. This study attempts to pinpoint the toxic lipid metabolite responsible for ER stress and apoptosis and offer mechanistic insight into its action.
Materials and methods: Pancreatic β-cell line, MIN6, and their palmitate-resistant (PR) negative controls, were treated chronically (48 h) with 0.4mM palmitate:0.92% BSA, as a model of lipid oversupply. A comprehensive lipidomic screen of β-cells, was undertaken via mass spectrometry. The level of apoptosis (DNA fragmentation ELISA) was determined following palmitate treatment and in combination with genetic intervention via overexpression of glucosylceramide synthase. Western blotting to measure ER stress-induced protein, CHOP, was performed and ER-to-golgi trafficking using a VSV-G_{t045}-GFP reporter assay were measured. Subcellular fractionation was undertaken using density gradient centrifugation.
Results: Palmitate pretreatment caused only very modest increases in mass of some major neutral phospholipids (triglyceride and phosphatidylcholine). There was also a 70% increase in glycosylceramide that was manifest in most side-chain species and cellular locations. Although total ceramide levels where unchanged, there were specific increases in the ER (56%) and lysosomal compartments (23%). A selective decrease in sphingomyelin species with side chain lengths greater than 20 carbons in length was also observed, consistent with a defective vesicular trafficking of longer chain ceramide species that impacts on corresponding sphingomyelin forms. Protein trafficking was also reduced by palmitate pretreatment, and this was overcome by overexpression of glucosylceramide synthase which metabolises ceramide. ER stress and apoptosis was also reduced under these conditions. The protein chaperone, phenyl-butryric acid did not rescue the sphingolipid alterations due to palmitate, nor were they reproduced by thapsigargin or tunicamycin, showing that the alterations are upstream, not downstream, of ER stress.
Conclusion: Our data provides a mechanistic link between ceramide accumulation and ER stress in lipotoxic β-cells and thereby reconciles two previously disparate areas of prior investigation. Specifically, we demonstrate that increases in ER ceramide underlie apoptosis in even mild models of lipotoxicity. Our results also lend support to the idea that protein overload, secondary to reductions in ER-to-golgi protein trafficking caused by ceramide, contributes to the induction of ER stress.

The decrease in insulin secretion by prednisolone involves activation of the endoplasmic reticulum stress pathway in INS-1E cells

M.L. Linssen[1], D.H. van Raalte[2], G.C.M. van der Zon[1], J. Kriek[1], J.A. Maassen[1,2], M. Diamant[2], B. Guigas[1], D.M. Ouwens[1,3];
[1]Molecular Cell Biology, Leiden University Medical Center, [2]Department of Internal Medicine/Diabetes Center, VU University Medical Center, Amsterdam, Netherlands, [3]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, Germany.

Background and aims: The glucocorticoid prednisolone (PRED) impairs multiple aspects of beta cell function in man, resulting in a decreased insulin secretory potential. One of the possible underlying mechanisms could be induction of endoplasmic reticulum (ER) stress, which leads to inhibition of gene transcription and protein synthesis. Here, we investigated whether PRED-induced ER stress contributes to beta cell dysfunction in INS-1E cells.
Materials and methods: INS-1E cells were treated with 700nM PRED, and insulin secretion in response to glucose and KCl was determined at different time points. mRNA and protein expression of various ER stress markers

(PERK, eIF2α, IRE1α, and XBP1s) were determined by real-time PCR and western blot, respectively.
Results: Exposure of INS-1E cells to PRED caused a time-dependent reduction in glucose-stimulated insulin secretion (GSIS). Inhibition of GSIS was already present 1 h after the addition of PRED, and occurred without affecting insulin content. This short-term treatment had no inhibitory effect on KCl-stimulated insulin secretion (KSIS). By contrast, prolonged incubation with PRED (20 h) abrogated both GSIS and KSIS, lowered insulin and PDX1 mRNA and protein expression, and increased the expression of the apoptosis marker cleaved caspase 3. These effects of PRED were preceded by a decrease in the phosphorylation of PERK and its substrate eIF2α, and an increase in the expression of the endonuclease IRE1α, and its target spliced XBP1s. Finally, all PRED-induced effects were reversed by the glucocorticoid receptor antagonist RU486.
Conclusion: PRED acutely inhibits insulin secretion by a mechanism which does not involve alteration of insulin content. By contrast, inhibition of insulin secretion by chronic PRED exposure can be ascribed to reduced insulin content resulting from ER-stress. We propose that PRED-induced dephosphorylation of the PERK/eIF2α-pathway lowers PDX1- and insulin- mRNA and protein levels through activation of IRE1α/XBP1s-pathway.

Losartan protect human pancreatic islets from glucotoxic ER and oxidative stress

Y. Pan[1], S. Dubois[1], R. Cassel[1], A. Mesnier[1], D. Bosco[2], C. Thivolet[1], A.-M. Madec[1];
[1]Faculte de Medecine Lyon-Sud, INSERM U.870, Oullins, France, [2]Departement of Surgery, Cell Isolation and Transplantation Center, Geneva, Switzerland.

Background and aims: In animal models and humans, chronic hyperglycemia is associated with alterations in beta-cell mass and function. Chronic high glucose concentrations increased glucose metabolism through oxidative phosphorylation. This causes mitochondrial dysfunction and excess production of reactive oxygen species (ROS) in beta-cells due to their low levels of ROS-detoxifying enzymes. Beta-cells present a developed ER in order to answer to high demand for synthesis of insulin. Recent data suggest that ER stress is present in human beta-cells and that this could be a common mechanism for the two major pathophysiological events in type 2 diabetes, insulin resistance and beta-cell failure. Data from prospective studies suggest a significant reduction in the risk of type 2 diabetes after blockade of the renin angiotensin system (RAS). Since RAS has been found in pancreatic islets, we hypothesized that these beneficial effects could be attributed to direct actions on islets. Our present study evaluates the effects of the Angiotensin II receptor blocker Losartan on stress induced by glucose in isolated human beta cells.
Material and methods: Human islets from 6 distinct donors were studied following 96 hrs in culture in presence of 5.5 mmol/l or 16.7 mmol/l glucose concentrations with or without 5 µmol/l Losartan during the last 48 hrs. ER stress-related mRNA, INS and VEGF mRNA expressions were detected by real-time RT-PCR, GRP78 protein expression and eIF2 α phosphorylation by Western-blot. Angiogenesis-related protein expression was measured by protein arrays. ROS levels were determined by measuring DCF oxidation and insulin secretion by IRMA.
Results: Insulin gene expression and protein secretion were significantly increased by 6.5 times at 16.7 mmol/l glucose compared to 5.5 mmol/l glucose (p=0.03; p=0.006, respectively). This increase was not modified by Losartan. Chronic high glucose exposure decreases VEGF mRNA and protein expression levels (20% and 64%, p=0.05 and p=3.10-6, respectively). Protein arrays showed that high glucose reduced expression of additional factors such as IGFBP2 by 53% (p=5.10-7) and IL8 by 24% (p=0.008). Losartan was able to reverse effects observed on protein expression of VEGF by 25%, p=0.05, IGFBP-2 by 100%, p=0.002 and IL8 by 100%, p=0.02. Chronic high glucose up regulates ROS levels by 60% (p=0.02). This effect was half abrogated by Losartan. GRP78, spliced XBP-1 mRNA expressions increased with glucose concentration, (x2.2;p<0.012, x1.5 ;p<0.009, respectively). The expression of CHOP, an ER stress marker of apoptosis, remained the same, suggesting that this chronic glucose treatment caused mild ER stress but not cell death. Moderate increase of GRP78 protein expression (x1.4) and eIF2α phosphorylation (x1.3) was observed with high glucose concentration. Addition of Losartan to 16.5mmol/l glucose medium reduced significantly ER stress markers' expression, GRP78 mRNA by 55% (p< 0.01), XBP1-s mRNA by 51% ;p<0.02) as compared to high glucose condition alone.
Conclusion: Chronic high glucose exposure of human islets reduces angiogenesis and parallely increases oxidative and ER stress. Blockade of islet RAS by Losartan modulates angiogenesis and protects islet cells against ER and oxydative stress. These findings may have important therapeutic consequences both for prevention of type 2 diabetes and islet transplantation.

New players in the beta cell ER stress response: UFM1 and UFBP1

K. Lemaire[1], R.F. Moura[2], M. Granvik[1], H.E. Hohmeier[3], N. Hendrickx[1], E. Waelkens[1], C.B. Newgard[3], M. Cnop[2], F. Schuit[1];
[1]Molecular Cell Biology, KU Leuven, [2]Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium, [3]Sarah W. Stedman Nutrition and Metabolism Center and Departments of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, USA.

Background and aims: To fulfil their demanding metabolic task - the regulated synthesis, storage and secretion of insulin - pancreatic beta cells possess a highly developed endoplasmic reticulum (ER). This may explain why beta cells are vulnerable for ER overload as was illustrated by heterozygous eIF2alpha^{ser51ala} mutant mice fed a high fat diet. Therefore, optimal functioning of the ER is essential for proper insulin folding and beta cell survival. Chronic imbalance between protein synthetic demands and ER folding capacity leads to ER stress and activation of the ER stress response to restore ER homeostasis. The aim of the present study was to identify new players in the ER stress response, starting from genome wide mRNA expression analysis and genes with unknown function which are highly expressed in islets. Ubiquitin-fold modifier 1 (UFM1), the most recently identified ubiquitin-like protein with unknown function, is proposed as being a new player in the beta cell ER stress response.
Materials and methods: mRNA expression analysis was performed by Affymetrix microarrays and confirmed by RT-PCR. Using STrEP-tag affinity purification and mass spectrometry we identified a new target of UFM1. The cellular localisation of UFM1 and its target was identified via cellular fractionation and immunocytochemistry. The effect of free fatty acids and of cyclopiazonic acid on ER stress and on apoptosis was analysed in INS1 cells treated with *Ufm1* specific siRNA. The influence of UFM1 and its target on ER associated protein degradation was analysed by overexpression of CD3δ, a known target of ERAD, in siRNA treated INS1 cells.
Results: Among a panel of 20 investigated organs and tissues, UFM1 is highly expressed in pancreatic islets of Langerhans and in other protein-secreting exocrine cell types (pancreatic acini, salivary glands, and seminal vesicles), both at the mRNA and protein level. We identified a highly conserved, unknown protein as a target of UFM1 and named it UFBP1 for UFM1-binding protein 1 containing a PCI domain. Both UFM1 and UFBP1 co-localised in the ER. Pharmacological induction of ER stress by cyclopiazonic acid (25 µM) enhanced expression of both *Ufm1* and *Ufbp1* (respectively 3.7-fold and 5.3-fold) in INS1 cells. This pharmacolocial effect was partially mimicked by addition of the free fatty acids oleate and palmitate which enhanced *Ufbp1* expression (respectively 1.7-fold and 2.4-fold). siRNA-mediated reduction of *Ufm1* or *Ufbp1* expression enhanced apoptosis upon ER stress stimulation and diminished ERAD as evidenced by less degradation of CD3δ.
Conclusion: Our data show for the first time that UFM1 via its target protein UFBP1 is a new molecular player in ERAD and ER stress-induced beta cell apoptosis.

Cell type-specific transcriptional regulation of 4E-BP1 under ER stress in MIN6 beta cells

H. Ishihara[1], C. Satake[2], R. Tominaga[2], S. Yamguchi[2], Y. Oka[2];
[1]Division of Diabetes and Metabolism, Nihon University, Tokyo, [2]Division of Molecular Metabolism and Diabetes, Tohoku University, Sendai, Japan.

Background and aims: Recent studies reveal that translational control of protein expression is activated in cells under stress conditions. We have recently identified translational control involving a transcriptional suppressor 4E-BP1 is important for beta-cell survival under ER stress and oxidative stress conditions. The *Eif4ebp1* gene, encoding 4E-BP1, is also shown to be a direct target of a transcription factor ATF4, a master regulator of gene expression in stress responses, in MIN6 insulinoma cells. In the current study, we investigated 4E-BP1 expression under ER stress in various cell lines.
Materials and methods: MIN6 cells and other cell lines were treated with thapsigargin and subjected to Western blot analysis. Luciferase reporter constructs containing varying lengths of the *Eif4ebp1* gene were generated and introduced into MIN6 cells and mouse embryonic fibroblasts (MEFs). Transcriptional activity of the *Eif4ebp1* gene fragments were analyzed in these cells.
Results: Although ER stress increased mRNA and protein levels of 4E-BP1 in MIN6 cells, little increases in 4E-BP1 protein levels were observed in response to thapsigargin in MEFs, COS7 and NIH3T3 cells as well as eight other cell lines tested, despite marked increases in stress marker proteins, ATF4 and CHOP. Expression of 4E-BP1 mRNA levels were not significantly increased in MEFs treated with thapsigargin neither, suggesting that lack of 4E-BP1 induction occurred at the transcriptional level. In order to gain insight into the difference in 4E-BP1 expression between MIN6 cells and MEFs, we examined different portions of the *Eif4ebp1* promoter and enhancer. An approximately 1 kbp region of the *Eif4ebp1* gene was found to be attributable to the different expression in response to thapsigargin treatment. Furthermore, we found that Smad signaling pathway are different between MIN6 cells and MEFs, and that lack of expression of a transcriptional coactivator of Smad might be involved in different expression of 4E-BP1 under ER stress.
Conclusion: Our results provide the evidence for cell type-specific transcriptional regulation of 4E-BP1 in MIN6 cells under stress conditions.

Metallothioneins and beta cell function during glucose or palmitate stress

N.S. Lund[1], K. Smidt[1], M.G. Jensen[1], T. Maxel[1], B. Brock[1], M. Penkowa[2], J. Rungby[1];
[1]Department of Pharmachology, University of Aarhus, [2]Department of Neuroscience and Pharmacology, University of Copenhagen, Denmark.

Background and aims: Metallothioneins (MT) are metalloregulatory proteins partly controlling intracellular and extracellular zinc metabolism. MT I and II are low molecular weight (6-7 kDa) nonenzymatic cysteine-rich proteins. Both are important for the regulation of pathophysiological processes that depend on zinc and the processes during which oxidative stress mobilizes zinc. MTs may influence survival of cells in several organs and affect transmitter systems depending on zinc ions for optimal function. MTs are highly inducible by e.g. endotoxins and glucocorticoids as well as by heavy metals such as zinc or copper. Beta cells depend on zinc ions for storage and secretion of insulin. Zinc metabolism in beta cells is regulated by a number of proteins transporting zinc across membranes, notably ZnT8 and ZnT3. Furthermore, cell survival may be influenced by zinc levels and thus by MTs. The aim of this study was to investigate the effects of MTs on insulin secretion, gene expression of the apoptosis-regulating genes BAX and BCL2 as well as the expression of ZnT3 and ZnT8.
Materials and methods: Glucose sensitive INS-1E cells were examined after exposure to varying doses of glucose or palmitate for 24 hours. 1. Beta-cells were exposed to 3.3mM, 6.6mM or 21mM glucose with or without Zn_7Metallothionein-2A (rabbit). 2. Beta-cells were exposed to palmitate 0 mM, 0.4 mM or 1.0 mM with or without Zn_7Metallothionein-2A (rabbit). All experiments were performed in replicas of 6. Gene expressions of BAX, BCL-2, Insulin, Zinc-transporters (ZnT3, ZnT5, ZnT8) and Metallothioneins (1A and 3) were investigated by RT-PCR and insulin secretion and content were determined by ELISA.
Results: Zn_7Metallothionein-2A did not change insulin gene expression. During basal conditions MT decreased insulin secretion (6.6 mM glucose) but MT increased the insulin secretion during stress (high glucose or high palmitate). The ZnT8 gene expression was decreased by Zn_7Metallothionein-2A at high palmitate and glucose concentrations. The ZnT3 gene expression was increased by Zn_7Metallothionein-2A after palmitate but decreased by MT at basal conditions. BAX/BCL ratio was decreased by Zn_7Metallothionein-2A during glucose stress, but showed no change with palmitate stress.
Conclusion: Manipulating intracellular zinc metabolism by exogenous MTs influence insulin secretion, the expression of zinc transporting proteins and genes related to apoptosis in a complex manner. Exogenous MTs seem to favour an enhanced insulin secretion during glucose or lipid stress and may affect the expression of apoptotic genes in a favourable direction. Induction of MTs may favourably influence beta cell function and survival, a complex mechanism of action involving also ZnTs needs clarification.

Dysfunction and proliferation of pancreatic beta cells by cyclic intermittent hypoxia

H. Ota, S. Tamaki, A. Itaya-Hironaka, A. Yamauchi, S. Sakuramoto-Tsuchida, T. Morioka, S. Takasawa, H. Kimura;
Nara Medical University, Kashihara, Japan.

Background and aims: Sleep apnea syndrome (SAS) is a highly prevalent sleep disorder characterized by cyclic intermittent hypoxia (IH). Accumulating evidence suggests that SAS is associated with glucose intolerance and insulin resistance independent of age, gender, smoking status, body mass index, and waist circumference. In addition to the development of glucose intolerance and insulin resistance, the progression to type 2 diabetes is dependent on the impairment of glucose-induced insulin secretion (GIS) from pancreatic beta cells and the compensatory replication of pancreatic beta cells to combat the presence of insulin resistance. However the direct effects of IH on GIS and beta cell replication have been obscured.
Materials and methods: Hamster insulinoma HIT-T15 cells, rat insulinoma RINm5Fcells, and isolated rat islets were exposed either to sustained hypoxia (SH) (1% O_2), 64 cycles/24 hours of intermittent hypoxia (IH) (5 min hypoxia/10 min normoxia (21%O_2)), or normoxia for 24 hours. After the treatment, HIT-T15 cells and rat islets were incubated in RPMI1640 medium containing 5.5 mM glucose (LG), or 22 mM glucose (HG) for 1h in normoxia. Insulin in the medium was measured by an ELISA kit. Real-time RT-PCR of insulin, CD38, glucose transporter 2, glucokinase, sulfonylurea receptor1, and L-type Ca channel1.2 was performed using normoxia- or IH-treated islet RNA as template. Cellular proliferation and apoptosis were measured by WST-8 assay and TUNEL method, respectively.
Results: The GIS of IH-treated HIT-T15 cells was attenuated, whereas GIS of the cells treated with normoxia was increased by HG ($p<0.01$). GIS from the isolated rat islets was also abolished by the treatment of IH. Real-time RT-PCR revealed that the level of insulin mRNA was unchanged by IH treatment. We then examined the mRNA levels of several genes involved in GIS in the islets. The mRNA levels of glucose transporter 2, glucokinase, sulfonylurea receptor1, and L-type Ca channel1.2 in IH-treated-islets were similar to those in normoxia-treated islets. In contrast, the mRNA level of CD38 in IH-treated islets was significantly lower than that in normoxia-treated islets (39% of the control), indicating possible dysfunction of the CD38-cyclic ADP-ribose signal system for insulin secretion in IH-treated beta cells. By WST-8 assay, the HIT-T15 cell proliferation was significantly increased by IH ($p<0.01$) and decreased by SH ($p<0.01$) compared to that of normoxia-trated cells. The cellular proliferation of RINm5F cells was also increase by IH, whereas apoptosis in RINm5F cells and HIT-T15 cells were unchanged by IH treatment. The mRNA level of Reg I, an autocrine/paracrine beta cell growth factor, was significantly increased by IH-treated RINm5F cells.
Conclusion: These results indicate that IH stress attenuates GIS and stimulates beta cell proliferation as compensatory response. It is quite possible that the cyclic change of hypoxia-reoxygenation, which occurs in SAS patients, induces beta cell dysfunction and proliferation, resulting in glucose intolerance and type 2 diabetes.

Pancreatic beta cell Uchl1 regulates glucose homeostasis in high-fat fed mice

K. Chu[1], H. Li[1], K. Wada[2], J.D. Johnson[1];
[1]Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada, [2]Degenerative Neurological Diseases, National Institute of Neuroscience, Tokyo, Japan.

Pancreatic beta-cells are professional secretory cells with substantial protein production and degradation demands. Defects in the production or secretion of insulin contribute to the pathogenesis of diabetes. Pancreatic beta-cells express ubiquitin C-terminal hydrolase L1 (Uchl1) is a component of the ubiquitination pathway, which deubiquitinizes polyubiquitin into monomers after proteasomal degradation, but its functional role has not been studied. Our previous proteomic screen suggested that Uchl1 protein was increased by the fatty acid palmitate at 5 mM glucose. Here, western blot analysis confirmed that Uchl1 protein was increased by 24-hour palmitate treatment at 5 mM, but surprisingly not 25 mM, glucose. Ubiquitin levels were reduced at high glucose condition independent of palmitate treatment. Mice harbouring the gracile axonal dystrophy (gad) mutation in the Uchl1 gene were used to study the role of Uchl1 in lipid-induced pancreatic beta-cell dysfunction. Gad mice exhibited normal body weight, glucose tolerance, and insulin tolerance, beta-cell mass and islet architecture on a normal chow diet. However, after 4 weeks of high fat feeding, male gad mice became glucose intolerant and without changes in insulin sensitivity. In these gad mice, the first phase of insulin secretion was impaired in both in vivo and in vitro studies. Intracellular calcium level was not affected, suggesting a specific defect in the exocytosis of insulin. Islets from Uchl1 mutant mice also exhibited an increase in ER-stress and apoptosis. Together, these data suggest that beta-cell UCHL1/gad may play a previously unappreciated role in glucose homeostasis.

Rapid alternations in DNA methylation patterns in insulin-producing beta cells correlate with changes in ambient glucose levels

E. Wallin Öhman[1], J. Staaf[1], R. Nilsson[1], M. Fraga[2], P. Bergsten[1];
[1]Department of Medical Cell Biology, Uppsala University, Sweden, [2]Department of Immunology and Oncology, National Center for Biotechnology, Madrid, Spain.

Background and aims: Elevated levels of glucose are characteristic of individuals with type 2 diabetes mellitus. Prolonged hyperglycemia is detrimental for insulin-producing beta-cells and leads to impaired glucose-stimulated insulin secretion and apoptosis. The harmful effects have been connected with changes in transcript levels of several genes. The aim was to determine whether extended episodes of hyperglycemia and the following alternations in gene expression are connected with changes in epigenetic patterns and, if so, such patterns can be reversed following a period of normoglycemia.
Materials and methods: Insulin-secreting INS-1E cells were cultured at 16.7 mM glucose for 1, 3, 5 or 7 days. For cells cultured for 7 days, the glucose concentration was reduced from 16.7 to 11 mM glucose during the last 2 days. Cells cultured at 11 mM glucose were used as controls. Cells were harvested after 1, 3, 5 and 7 days and total DNA extracted for analysis of DNA methylation. After sodium bisulfite treatment, DNA was amplified by PCR and subsequently sequenced. DNA methylation patterns were measured at four different sites in the repetitive DNA segment Long Interspersed Nucleotide Element (LINE) 1. The methylation status of this segment is known to be representative of global DNA methylation patterns.
Results: INS-1E cells cultured at 16.7 mM glucose for 24 hours showed no changes in methylation of the CpG sites within LINE1. In contrast, after 3 days a significant change in the methylation patterns was observed in cells exposed to 16.7 mM glucose. No further change was observed after 5 days of exposure to the hyperglycemic milieu. Interestingly, methylation patterns were reversed back to those observed in control cells when cells cultured at 16.7 mM glucose for 5 days were exposed to 11 mM glucose for an additional 2 days.
Conclusion: Exposure to elevated glucose levels induces global epigenetic changes in the beta-cell within only a few days. These changes can be reversed by normalization of the glucose levels. Glucose-induced epigenetic changes may thus contribute to altered transcription levels associated with hyperglycemia. These findings call for experimentation addressing epigenetic changes of specific genes. The results illustrate how environmental factors affect gene regulation and may give insight into mechanisms connected with development and reversal of hyperglycemia and thus serve as a model for disease progression and recovery in type 2 diabetes mellitus.

A novel bioinformatics approach combining array profiling and independent component analysis identifying microRNAs with potential roles in beta cell maturation and dysfunction

T. Fløyel[1], C.H. Bang-Berthelsen[1], L. Pedersen[2], P.H. Hagedorn[3], F. Pociot[1,4];
[1]Hagedorn Research Institute, Gentofte, Denmark, [2]Niels Bohr Institute, University of Copenhagen, Denmark, [3]AstraZeneca, Lund, [4]Institute for Clinical Science, University of Lund, Lund, Sweden.

Background and aims: The selective β-cell destruction taking place in type 1 diabetes (T1D) is believed to involve a sensitivity to interleukin-1β (IL-1β) that is acquired during β-cell maturation and has been associated with the transcription factor Pancreatic and duodenal homeobox 1 (Pdx1). microRNA (miRNA) repress gene expression posttranscriptionally through mRNA degradation or translational inhibition. Several miRNAs have been associated with β-cell differentiation or dysfunction. The aim of the study was to identify candidate miRNAs by using a cellular model of acquired IL-1β sensitivity and a novel bioinformatics approach.
Materials and methods: Array profiling was performed on miRNA and mRNA expression levels in a β-cell line with inducible Pdx1 expression (INSrαβ) in response to Pdx1 induction alone or in combination with IL-1β exposure. Independent component analysis (ICA) was applied to decompose the mRNA profiling data into independent components (ICs), thus identifying biologically coherent groups of genes. For identification of inverse cor-

related miRNA and mRNA expressions Pearson correlation coefficients were calculated. Predicted miRNA targets were defined as mRNAs with a given miRNA 6mer seed match in their 3'UTR. INS-1 cells were used to verify the expression of the identified miRNAs.
Results: Array profiling identified eight miRNAs (miR-124, miR-128, miR-192, miR-194, miR-204, miR-375, miR-672 and miR-708) with differential expression in response to Pdx1 induction and/or IL-1β exposure (Bonferroni corrected $p<0.1$). Four of the eight miRNAs show a significant enrichment of predicted targets among highly inverse correlated mRNAs ($q<0.01$), indicating miRNA-mediated repression of these mRNAs. Performing ICA on the mRNA data revealed five highly significant ICs (Bonferroni corrected $p<0.0001$) correlating to the experimental conditions, as shown by a significant enrichment of known Pdx1 and IL-1β regulated genes in the respective ICs ($p<0.05$). Interestingly, all eight miRNAs can be represented (percent variance explained >97%) by a superposition of the five ICs. Further, testing for enrichment of ICA-identified genes in KEGG-annotated pathways identified 25 pathways e.g. Type 1 Diabetes Mellitus, Maturity Onset Diabetes of the Young and Type 2 Diabetes Mellitus ($q<0.05$). Except for miR-124, there was a good resemblance between the IL-1β-induced miRNA expression changes in the INS-1 cells and the Pdx1-induced INSrαβ cells.
Conclusion: The mRNA expression is influenced by a number of factors such as accessibility, transcription factor binding and miRNA repression, thus few mRNAs have a clear inverse correlation with their targeting miRNAs. Here, ICA was applied as an attempt to filter all the various contributions from each other. The result was an identification of eight miRNAs with potential involvement in β-cell maturation and dysfunction. Interestingly, the miRNAs appear to directly or indirectly affect pathways of relevance to disease mechanisms in T1D.

MicroRNA miR-187 is reduced in human pancreatic islets from type 2 diabetic donors and in glucagon-secreting cells following palmitate treatment

G. Sebastiani[1,2], F.A. Grieco[1,2], E.T. Maniscalchi[3], S. Piro[3], P. Marchetti[4], F. Purrello[3], F. Dotta[1,2];
[1]University of Siena, [2]Fondazione Umberto Di Mario, Siena, [3]University of Catania, [4]University of Pisa, Italy.

Background and aims: The pancreatic islet damage during type 2 diabetes (DM2) is mediated by lipotoxicity phenomena with consequent beta cell dysfunction and increase in glucagon secretion. *In vitro* treatment with palmitate is sufficient to mimic a functional damage in pancreatic islets similarly to what observed in DM2. MicroRNAs are small endogenous RNAs, whose function is to pair mRNAs 3'UTRs regions of protein-coding genes, negatively affecting their translation or stability. MicroRNAs are involved in cellular differentiation and proliferation as well as in endocrine pancreas development, in regulation of insulin secretion and of insulin signalling. We have previously shown a differential miRNAs expression profiling in DM2 vs control human pancreatic islets characterized by a major downregulation of miR-187 expression, which resulted virtually undetectable in DM2 islets. Consequently, the aim of the present study was to analyze the effects of palmitate treatment on the alpha cell component of the pancreatic islets in terms of miR-187 expression, in order to establish whether such treatment could mimic in vitro the scenario present in the type 2 diabetic islet.
Materials and methods: Experiments were performed employing the alphaTC1-6 cell line, which was treated with palmitate 0.5 mM for 48h. Quantitative analysis of miR-187 and of islet specific miR-375 and miR-7 expression was performed using stem loop specific primers for reverse transcription followed by real time PCR. All values were normalized to U6 endogenous RNA.
Results: A 49±22% reduction of miR-187 ($p<0.05$) was observed in alphaTC1-6 cells following palmitate treatment, while islet-specific miR-375 and miR-7, whose expression was not found altered in DM2 islets, resulted unaffected. Of note, the computational analysis of miR-187 mRNAs targets with TARGETSCAN and MIRANDA algorithms revealed genes of potential interest such as glucagon, the alpha-cell transcription factor Pax6 and the insulin receptor.
Conclusion: This study demonstrates that *in vitro* treatment with palmitate of alphaTC1-6 cells determines a reduction in miR-187 expression that is similar to that observed in pancreatic islets from type 2 diabetic patients, thus suggesting that an altered expression of miR-187 could be involved in the islet dysfunction in DM2 and therefore may represents a potential therapeutic target.

MicroRNA differences in human islets and glucose-sensitive tissues

C. Bolmeson, J.L.S. Esguerra, D. Speidel, L. Eliasson, C.M. Cilio;
Dep of Clinical Sciences, Lund University, Malmo, Sweden.

Background and aims: We aim to identify microRNAs (miRNAs) that are expressed in the human pancreatic islets compared to other glucose-sensitive tissue such as liver and skeletal muscle. The hypothesis is that specific miRNAs expression affects the translation of messenger RNAs that are involved in glucose-stimulated insulin secretion (GSIS).
Materials and methods: We profiled 322 miRNAs in the islets of a human donor, as well as commercial liver and skeletal muscle RNA using locked nucleic acid (LNA)-based microarray. The eight most highly expressed miRNAs in islets compared to liver and skeletal muscle were selected, and expression in 16 additional human islet donors were validated using quantitative PCR. The effects of GSIS on miRNAs expression were investigated by incubating the islets for 1 hour at different glucose concentrations. Insulin release from intact islets was determined by radioimmunoassay. Bioinformatics predictions of miRNAs targets were filtered by available mRNA expression data, and enriched for gene ontology terms.
Results: We found a correlation between mir-375, mir-127 and mir-184 and insulin biosynthesis (Spearman R = 0,8022, p = 0,0005). Surprisingly, all three miRNAs were negatively correlated to insulin secretion. Hierarchical clustering of the global islet miRNAs profile allowed to separate islet-specific miRNAs from liver and muscle-specific miRNAs. Ten qPCR-validated miRNAs displayed expression differences in all tissues. Bioinformatic analysis revealed that the predicted miRNAs targets were enriched for genes with known role in insulin secretion.
Conclusion: In conclusion, high levels of islet mir-375, mir-127 and mir-184 may directly or indirectly affect insulin-secretion negatively. Our results also depict a role of islet-specific miRNAs in pathways of importance for type 2 diabetes and maturity onset diabetes of the young (MODY).

Glucagon stimulates glucagon gene transcription in mouse and human islets by an autocrine feedback loop

T. Moede, I.B. Leibiger, P. Vaca-Sanchez, P.-O. Berggren, B. Leibiger;
Dept. Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: The glucagon gene is expressed in pancreatic alpha-cells, intestinal L-cells and specific neurons, but only the alpha-cell produces and secretes glucagon due to different posttranslational processing. We have demonstrated that secreted glucagon positively regulates the transcription of its own gene in the pancreatic alpha-cell line alphaTC1-9. The molecular mechanism underlying this positive autocrine feedback involves the glucagon receptor, protein kinase A and C and the transcription factor CREB. Because these observations were made utilizing a cell line system, the aim of this study was to verify whether this positive feedback mechanism also exists in mouse and human pancreatic islets.
Materials and methods: Mouse islets were isolated from 4 month old BALB/C mice and cultured for 72 h in RPMI 1640 medium containing 10% fetal calf serum (FCS). Human islets were cultured in RPMI 1640 medium containing 10% FCS for 72 h after arrival prior to experiments. Islets were stimulated by either 2 mM glucose for 15 min or 200 nM glucagon for 5 min at 11 mM glucose in RPMI 1640 medium containing 10% FCS. After stimulation the islets were returned to fully supplemented RPMI 1640 medium. For inhibitor experiments the islets were incubated with the pharmacological inhibitors for 30 min prior to and during the stimulation. 60 min after the start of stimulation RNA was isolated from the islets. Changes in glucagon mRNA levels were then determined by QPCR normalized to cyclophilinA mRNA levels.
Results: Stimulation of islets with low glucose (2mM) led to a 1.4±0.1 fold increase in glucagon mRNA levels. Addition of exogenous glucagon for 5 min resulted in a 3.0±0,1 (mouse) or 2.5±0.2 (human) fold increase of glucagon mRNA. This increase was abolished in both mouse and human islets by treatment with 20 nM glucagon receptor antagonist II (Merck), a specific pharmacological inhibitor of the glucagon receptor, demonstrating the critical importance of glucagon receptor signalling. To verify the involvement of protein kinase C and protein kinase A in the stimulation of glucagon gene transcription by glucagon, we incubated islets with either a protein kinase A inhibitor (100 μM RPCAMPS) or a protein kinase C inhibitor (150 nM bisindolylamide II). Either treatment abolished the stimulatory effect of glucagon in human and mouse islets.
Conclusion: Our findings demonstrate that secreted glucagon up-regulates glucagon gene transcription in both mouse and human islets through an au-

tocrine feedback loop involving the glucagon receptor and protein kinases A and C.

Impact of a stabilized human reg3a protein on islet neogenesis and glycaemic control
C.S. Levetan[1], A.J. Peters[2], K.J. Novelli[3], B.E. Marks[4], A.E. Katz[4], R.G. Peterson[5], L.V. Upham[6];
[1]Chestnut Hill Hospital, Philadelphia, [2]Unit on Cognitive Neurophysiology and Imaging, National Institutes of Health, Bethesda, [3]Cabrini College, Rosemont, [4]Thomas Jefferson University School of Medicine, Philadelphia, [5]The University of Notre Dame, South Bend, [6]CureDM, Inc., Wynnewood, USA.

Background and aims: We set forth to compare the impact of a 14 amino acid bioactive region within the human Reg3a gene protein known as Human proIslet Protein (HIP2) on islet neogenesis and glucose-lowering ability to a stabilized form of this protein. The *Reg* gene is upregulated during new onset in type 1 diabetes and among many mammalian species following acute pancreatic injury and may be a potential agent to reverse type 1 and 2 diabetes. Reg3a is hypothesized as an initiating trigger for islet neogenesis and has been shown in animal models to result in formation of new functional islets containing alpha, beta gamma and delta cells. HIP was previously shown to significantly 1) increase insulin levels in human pancreatic ductal tissue and 2) lower glucose levels and increase islet numbers in STZ-rendered diabetic mice.
Materials and methods: The half-life of native HIP2 is 1.2 minutes. We stabilized HIP2 to enhance its potential efficacy as a human drug candidate. HIP was modified by blocking the ends, PEGylation and dimerization with *in vitro* trials conducted in a PANC1 cell line. A candidate was selected based upon improved half-life (20.4 minutes) without evidence of cell damage. *In-vivo* trials were conducted among STZ-rendered diabetic mice. At the end of the 39 day study, mice were fasted for 12 hours.
Results: Placebo-treated mice had significantly higher fasting glucose levels of 258.00 ± 84.5 mg/dL compared to stabilized HIP2B-treated animals with 106.7 ± 0.58 mg/dL (p=0.046). HIP2B treated mice had significantly lower daily random glucose levels compared to controls (Figure 1). The stabilized HIP2B group had a three-fold higher number of islets staining for insulin, glucagon and somatostatin compared to the placebo group (94.00 ± 32.74 and 31.67 ± 15.28 p=0.040). Total islet area was significantly greater in the stabilized HIP2B group compared to placebo (416,714.67 μm^2± 121,389.01 and 127,410.67 μm^2± 96930.78 p=0.032). There were no differences between islet size between the stabilized HIP2B group and placebo (p= 0.518).
Conclusion: HIP2B may address key pathological issues to reverse diabetes. For humans to maintain the success seen in mice may require lifestyle modifications among type 2 patients and concomitant usage of immune therapy among type 1 patients. Human trials with stabilized HIP2B among type 1 and 2 patients will commence in the coming year.

Growth arrest specific protein 6 (gas6) and its receptors expression and signalling in beta cells
V.V. Sharoyko[1], T. Koeck[1], C. Ekman[2], N. Wierup[3], F. Sundler[3], B. Dahlbäck[2], H. Mulder[1];
[1]Clinical Sciences, [2]Laboratory Medicine, Lund University, Malmo, [3]Experimental Medical Science, Lund University, Lund, Sweden.

Background and aims: The growth arrest-specific protein 6 (GAS6) belongs to the family of plasma vitamin K-dependent proteins. It shows homology (~40%) to the plasma anticoagulant protein S, another gamma-carboxylated protein. GAS6 exhibits growth factor-like effects, as it interacts with receptor tyrosine kinase, such as Axl, Tyro3 and Mer. GAS6 and Axl, Tyro3 and Mer have further been implicated in inflammation, cytokine production, immune responses, hemostasis, and cancer. It was therefore of major interest to study GAS6 signalling in islets and clonal beta-cells.
Materials and methods: Glucose-responsive INS-1 832/13 insulinoma beta-cells and human pancreatic islets were used. TaqMan qRT-PCR analysis was applied to measure cytokine mRNA expressions. Immunoblotting and immunocytochemistry were used to detect GAS6 and its receptors in human pancreatic islets and INS-1 832/13 beta-cells as well as GAS6-induced phosphorylation of Axl [pY779] and Akt/PKB [pS473]. To asses further GAS6-stimulated global post-translational protein modifications, especially tyrosin phosphorylation, in INS-1 832/13 beta-cells 2D-PAGE and immunoblotting were combined with stable isotope labeling with aminoacids (13C615N1Leu) in cell culture (SILAC) to quantify the effect of GAS6 by mass spectrometry. To do so, protein samples extracted from 2D-gels were analyzed by MALDI-Trap and LC-MS/MS.
Results: Immunoblotting and immunocytochemistry showed expression of GAS6 and its receptors Axl and Tyro3 but not Mer in human pancreatic islets. Immunoblotting for Axl [pY779] and Akt/PKB [pS473] detected phosphorylation of Axl-receptor and Akt/PKB induced by 400 ng/ml GAS6 in INS-1 832/13 cells. Thus, treatment of INS-1 832/13 beta-cells with GAS6 leads to Axl-receptor mediated PI3-kinase/Akt signalling. Furthermore, the comparison of untreated and GAS6-stimulated INS-1 832/13 beta-cells by 2D-immunoblotting for phospho-tyrosine showed 23 modified proteins. Up to now, glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and glucose regulated protein 78 (GRP78/BiP) were identified by mass spectrometric peptide sequencing and changes in GAS6-induced protein expression and tyrosine phosphorylation quantified based on SILAC. These GAS6-induced protein modifications are associated with preventive effect of GAS6 on high glucose-induced increase in TNF-alpha mRNA expression in INS-1 832/13 beta-cells.
Conclusion: We show for the first time that GAS6 and its receptors are present in pancreatic islets and beta-cells and alter TNF-alpha production. The employed proteomic methods revealed that (i) activation Axl/PI3-kinase/Akt signalling and (ii) tyrosine phosphorylation of GAPDH and GRP78, as part of the cellular response to GAS6-stimulation downstream of PI3-kinase and Akt, might be involved in the GAS6 effects on cytokine production. These effects of GAS6 on pancreatic beta-cells demand further investigations.

Complement receptor C5aR is expressed in pancreatic islets and affects glucose-induced insulin and glucagon secretion
V. Nagaraj[1], U. Krus[1], A. Blom[2], E. Renström[1];
[1]Department of Clinical Sciences, [2]Department of Laboratory Medicine, Lund University, Malmö, Sweden.
Background and aims: Complement factors form an important part of the humoral innate immune system and have been implicated in the pathogenesis of autoimmune diseases, including type 1-diabetes. There is however accumulating evidence that the complement system can modulate pancreatic islet function and may also be an important player in the development of type 2-diabetes. For example, patients with type 2-diabetes exhibit increased neutrophil levels of C5a. C5a is produced as a result of complement activation from complement factor C5 and exerts its effect by binding to its receptor C5aR. In this study we have detailed the expression of human complement system in normal islets, and investigated the role of the C5a and C5a receptor antagonist (C5aRant) in human islet function.

Materials and methods: Expression in human islets: Total RNA was isolated from pancreatic islets from 34 non-diabetic donors using the AllPrep RNA Mini Kit and analyzed using Gene 1.0 ST whole transcript based assays. Secretion assay: Insulin and Glucagon secretion was measured by RIA using donor human islets obtained from the Nordic Network of Clincial Islet Transplantation (Prof. Olle Korsgren, Uppsala University) in collaboration with the Lund University Diabetes Center Human Tissue Lab (Dr. Jalal Taneera).
Results: Microarray analysis demonstrated the presence of transcripts of nearly all the complement genes in human pancreatic islets. Next, the effect of C5a on insulin and glucagon secretion was investigated using normal and diabetic human islets. In normal human islets, C5a failed to affect glucose-stimulated insulin secretion (16.7mM). However, addition of C5a together with the C5a receptor antagonist (C5aRant), significantly increased insulin release by (32%; P=0.003; n=38). It was ascertained that the C5aR antagonist alone did not stimulate insulin release. Interestingly, in diabetic human islets C5a and C5aR antagonist did not produce any significant effects on insulin secretion. Similar observations were made for glucagon measurements. In the normal human islets, C5a had no significant effect, whereas in the simultaneous presence of C5a and C5aRant an increase in the amount of glucagon released was observed (37%; P=0.003; n=37). In diabetic islets, the effects on glucagon secretion by C5a and the C5a receptor antagonist were essentially similar to normal islets; C5a alone had no clear effect, whereas addition of the C5a receptor antagonist C5aRant produced a clear increase (57%; P<0.0001; n=12) in glucagon release.
Conclusion: Human islets express all complement factors. The C5a signalling system affects both insulin and glucagon secretion. In addition, C5a signalling in the beta-cell may be altered in type 2-diabetes.

p140Cas-associated protein (Cap), expressed in beta cell, suppresses insulin secretion
M. Yamauchi[1], H. Okada[1], K. Fujioka[1], I. Mori[1], T. Hanamoto[1], T. Ikeda[1], Y. Uno[1], H. Morita[1], K.-I. Nagata[2], K. Kajita[1], T. Ishizuka[1];
[1]General Internal Medicine, Gifu University Graduate School of Medicine, Gifu City, Japan, [2]Molecular Neurobiology, Developmental Research, Aichi Hyman Service Center, Kasugai, Japan.

Background and aims: p140Cap is a multidomain adaptor protein that was first found as an interactive partner of p130Cas (Crk-associated substrates), a protein highly tyrosine phosphorylated in fibroblasts transformed with v-Src or v-Crk oncogene. In non-transformed cells, p130Cas is tyrosine phosphorylated upon ligation of integrins. p140Cap is also tyrosine phosphorylated upon integrin-dependent adhesion or epidermal growth factor signaling, indicating a possible role in cell matrix and in growth factor signaling. In addition, p140Cap was also identified as a synaptosome-associated protein of 25 kDa (SNAP-25)-interacting protein. SNAP-25 plays a major role in membrane docking of synaptic vesicles during neurotransmitter release. Subcellular fractionation analysis suggested that p140Cap interacts with cortical cytoskeleton as well as SNAP-25, it may contribute to neuronal secretion in brain. We had identified a multidomain adaptor protein, vinexine, of which third Src-homology domain interacts with the C-terminal Pro-rich motif of p140Cap with screening study of p140Cap-binding proteins in rat brain. In this study, we examined the possibility whether p140Cap and vinexine might be expressed in the pancreas islet, since proteins involved signal transductions in neurons are often shared with endocrine cells.
Materials and methods: Immunohistological studies using anti-p140Cap antibody and anti-vinexine antibody were performed in rat pancreas. Next, to evaluate the role of p140Cap, the effect of gene silencing using the complex of Lipofectamine 2000 and shRNA on glucose-stimulated insulin secretion was examined in Ins-1 cells and cultured rat insulinoma cells. We studied effect of progression of diabetes mellitus on the expression of p140Cap in Otsuka Long Evans Tokushima Fatty (OLETF) rats, a model of obese type 2 diabetes.
Results: Although p140Cap is associated with vinexine in neurons, p140Cap was detected in beta cells, whereas vinexine in alpha cells in islet. Insulin secretion was elevated in the presence of glucose with time and dose depending manner in Ins-1 cells. Knockdown of p140Cap with shRNA enhanced glucose-stimulated insulin secretion to 260% without increasing in basal insulin level. Silencing of p140Cap resulted in an increase of high potassium-stimulated insulin secretion, but no increase in glucose-stimulated one in MIN6 cells. Our results strongly suggested that p140Cap might negatively regulate insulin secretion in beta cells. Moreover, both immunoreactive insulin and p140Cap were detected in the same cells of pancreas islets in control rat, while poor concordance was observed in OLETF rats. In conclusion, p140Cap and vinexine were recognized in beta cells and alpha cells, respectively.
Conclusion: p140 Cap was expressed in beta cell, which may negatively regulate insulin secretion.

Expression and function of equilibrative nucleoside transporter 3 in beta cells
B. Liu[1], K. Hussain[2], C.C. Richardson[1], P.M. Jones[1], S.J. Persaud[1];
[1]Diabetes Research Group, King's College London, [2]Institute of Child Health, University College London, United Kingdom.

Background and aims: Loss of function recessive mutations in the SLC29A3 gene encoding ENT3 have been identified in a novel diabetes syndrome called "pigmented hypertrichotic dermatosis with insulin-dependent diabetes" (PHID). ENT3 is a member of the equilibrative nucleoside transporter family that function primarily as cellular mediators of nucleoside uptake. It is distinct from other ENTs due to its predominant intracellular localisation. Recently, it was reported that in human hepatocytes and placental tissues, ENT3 is expressed mainly in the mitochondria, to which it transports native nucleosides. This study aimed to investigate the expression and function of ENT3 in pancreatic beta cells.
Materials and methods: ENT3 expression was examined by RT-PCR, Western blotting and immunohistochemistry. The subcellular localisation of ENT3 was determined by exposure of MIN6 beta cells to MitoTracker red CMXRos before subsequent immunostaining with an ENT3 antibody. Cytokine-induced apoptosis was quantified by caspase 3/7 assays in MIN6 cells that had been either exposed to the ENT inhibitor dipyridamole or transfected with ENT3 siRNAs.
Results: PCR amplifications using human and mouse ENT3 primers produced single products of the appropriate sizes from human islet, MIN6 beta cell, mouse islet, and exocrine pancreas cDNAs. Western blotting using an ENT3 antibody detected a 52kDa protein in human islets, mouse islets and exocrine pancreas. A 65kDa protein was detected in MIN6 cells, mouse islets and exocrine pancreas, which most likely represents a post-translationally modified form of ENT3. Immunohistochemistry using archived human pancreas sections demonstrated extensive ENT3 immunostaining of beta cells, which was confirmed by co-staining with an anti-insulin antibody. Furthermore, immunostaining of MIN6 cells that had been exposed to MitoTracker with an ENT3 antibody showed co-localisation of ENT3 to beta cell mitochondria. Inhibition of MIN6 cell ENTs with 10 μM dypridamole resulted in significant increases in basal apoptosis (caspase 3/7 assay luminescence units; dypiridamole-treated vs. control: 47,741 ±2,249 vs. 42,550 ±840; n=8; P <0.05) and in cytokine-induced apoptosis (725,136 ±28,919 vs. 624,147 ±24,279; n=8; P <0.05). More specifically, MIN6 cells transfected with siRNAs directed against mouse ENT3 showed significantly enhanced levels of cytokine-induced beta cell apoptosis compared to control cells transfected with scrambled siRNAs (139,634 ±4,613 vs. 106,426 ±3,001; n=8; P <0.001).
Conclusion: These observations demonstrate that ENT3 is predominantly expressed by islet beta cells, with lower expression levels detected in the exocrine pancreas. Our results also indicate that ENT3 co-localises with mitochondria in MIN6 cells, suggesting a functional role in beta cell physiology. Finally, reduced ENT3 activity or expression is associated with enhanced beta cell apoptosis, which might account for the occurrence of autoantibody-negative insulin-dependent diabetes in individuals with non-functional ENT3 mutations.

534

The role of neurexins in the exocytosis of insulin granules from beta cells
M. Mosedale, A.T. Suckow, S. Egodage, R.C. Calma, S.D. Chessler;
Medicine, University of California, San Diego, La Jolla, USA.

Background and aims: Pancreatic β cells express many protein constituents of the neurotransmitter exocytotic machinery including a family of transmembrane, synaptic adhesion molecules called neurexins (NRXNs). In the brain, α-NRXNs help organize the neuronal exocytotic machinery via extracellular interactions with other synaptic proteins and via intracellular interactions with the exocytotic proteins CASK, Mint, Munc18, and Syntaxin. We hypothesized that α-NRXNs play a comparable role in β cells, participating

in insulin secretory granule docking and exocytosis. The aims of this study were:
1) to characterize NRXN expression in β cells.
2) to determine if NRXN contributes to insulin granule exocytosis.
Materials and methods: Plasma membrane purification, western blot analysis, immunostaining, and absolute RT-qPCR were used to examine NRXN expression and localization in β cells. Immunoprecipitation was used to identify NRXN binding partners in the INS-1E β-cell line. To test whether NRXNs are involved in insulin secretion, we examined the effect on glucose-stimulated insulin secretion of NRXN1 knockdown using siRNA and of NRXN1 overexpression in INS-1E β cells. Knockdown and overexpression experiments were also conducted by measuring glucose-stimulated human growth hormone (hGH) secretion from cells cotransfected with hGH. Constitutive secretion in knockdown experiments was evaluated by cotransfecting NRXN1 siRNA with secreted alkaline phosphatase (SEAP) and measuring SEAP secretion at basal (2.5mM) and high (15mM) glucose. Western blot analysis was used to examine NRXN protein levels in INS-1E β cells after high glucose stimulation.
Results: We determined that NRXN protein is expressed on the β-cell surface and is not present in other islet cell types. NRXN1α and 2β are the most abundant NRXN isoforms in the β cell, with transcript levels comparable to those in brain. CASK, Syntaxin1 and Munc18 coimmunoprecipitated with NRXN1 from INS-1E β cells. Decreased NRXN1 expression after siRNA treatment of INS-1E cells resulted in a 54% increase ($p<0.05$) in insulin secretion at high glucose but had no effect on basal insulin secretion. This result was confirmed by measuring secretion of transfected hGH, which is packaged and secreted in insulin-containing secretory granules. NRXN1 knockdown did not affect constitutive secretion. Increased levels of NRXN1 had no effect on secretion at high glucose but resulted in a slight (24%) but consistent increase in basal secretion. After 1h of glucose stimulation, NRXN1 protein levels decreased by 33% in non-transfected and 40% in NRXN1-overexpressing INS-1E β cells ($p<0.05$).
Conclusion: We conclude that NRXN1 is an integral component of the β-cell submembrane secretory machinery. NRXNs are involved in the exocytosis of insulin granules from β cells, possibly by organizing the exocytotic machinery and/or by contributing to the granuphilin-mediated docking of granules at the β-cell surface. Increased insulin secretion after NRXN1 gene silencing and the decrease in NRXN1 levels observed during glucose stimulation suggest that NRXN1, like granuphilin, contributes to the negative regulation of insulin release. Future work will determine the role of NRXNs in the docking, priming and fusion steps of insulin granule exocytosis.

Neuroligin-2 increases insulin expression and secretion in pancreatic beta cells via extracellular binding interactions
S.D. Chessler[1], I.R. Sweet[2], S. Egodage[1], D. Comoletti[3], P. Taylor[3], A.T. Suckow[1];
[1]Department of Medicine, University of California, San Diego, La Jolla, [2]Department of Medicine, University of Washington School of Medicine, Seattle, [3]UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, USA.

Background and aims: The pancreatic β-cell secretory apparatus is similar to that used by neurons for synaptic exocytosis. Many of the scaffolding and vesicular proteins important for neurotransmitter secretion are key components of the β-cell insulin secretory machinery. In neurons, extracellular interactions of neuroligin proteins with either neurexins or other synaptic proteins help to drive the recruitment of the exocytotic machinery to the axonal membrane. These transmembrane, synaptogenic adhesion molecules are of particular interest because a specific subset is expressed by β cells and because neuroligin-2 (NL-2) has been implicated by our group in the regulation of insulin secretion. These results along with previous studies demonstrating a role for neuroligins in the maintenance and differentiation of the neurotransmitter release machinery in the brain and the importance of cell-cell contacts in the regulation of insulin secretion led us to test the hypothesis that NL-2 helps to drive the assembly of the β cell secretory apparatus through extracellular interactions that facilitate β cell maturation and regulated insulin secretion.
Materials and methods: Antibodies targeted to the NL-2 extracellular domain and recombinant soluble NL-2 were utilized to test for the presence of NL-2 protein and NL-2 binding partners on the β cell surface. The role of extracellular interactions involving NL-2 in contact-enhanced stimulus-secretion coupling and β-cell insulin expression was tested by assessing insulin secretion and content after co-culturing MIN-6 and INS-1E β cells with other cells (HEK293) transfected with NL-2 or control expression constructs. Soluble NL-2 protein was utilized to disrupt extracellular protein interactions in rat islets and MIN6 cell cultures. The binding of radioiodinated, recombinant NL-2 to the surface of intact β cells was analyzed by determination of competitive binding curves.
Results: Fluorescence flow cytometry reveals that NL-2 is expressed on the surface of INS-1E and MIN-6 β cells. Binding of NL-2 to the β cell surface was also detected, with INS-1E and MIN6 β cells each yielding two distinct populations with different binding properties. The dissociation constant (K_d) of NL-2 with its binding partner on the β-cell surface is 15 nM, lower than would be expected if the binding partner were neurexin. Addition of soluble NL-2 to the culture media of isolated rat islet or INS-1E β cells reduces insulin secretion by up to 70% in a concentration-dependent manner. Half-maximal inhibition of insulin secretion is achieved with 9 nM soluble NL-2, a concentration approximately the same as the K_d of the binding interaction. Coculture of β cells with cells expressing neuroligin-2 increased stimulated insulin secretion by 37% ($p<0.01$) and cellular insulin content by up to 40% ($p<0.05$).
Conclusion: NL-2 is expressed on the β cell surface and binds with high affinity to another β-cell surface protein. Extracellular interactions involving NL-2 increase insulin expression and secretion by β cells. These results are consistent with the hypothesis that NL-2 promotes the development and maintenance of the insulin secretory machinery in β cells through trans-cellular interactions.

Inhibition of beta-secretase activity affects pancreatic beta cell function
P. Casini, S. Piquer, S. Casas, J. Altirriba, R. Gomis, A. Novials;
Laboratori de Diabetis i Obesitat. IDIBAPS. Hospital Clínic. CIBER de Diabetes y Enfermedades Metabolica Asociadas (CIBERDEM), Barcelona, Spain.

Background and aims: BACE1 and BACE2 (ß-site APP-cleaving enzyme 1 and 2) are proteases sharing typical structural features with type I membrane associated aspartyl proteases. Both enzymes have been found to be differently expressed in various human tissues and, in particular, BACE1 appears to be more abundant in the brain, where it is involved in the pathogenesis of Alzheimer's disease as the ß-secretase generating the ß-amyloid peptide. In all amyloidogenic diseases, including Alzheimer's Disease and Diabetes, abnormally folded and insoluble proteins accumulate within or around cells and interfere with their function. Although the ß-secretases BACE1 and BACE2 have also been found in the pancreas, their functional role in this tissue still remains unknown. This report is aims to characterize the localization of BACE proteins in the human pancreas and to determine their role on pancreatic function.
Materials and methods: The enzymatic activity of BACE was detected in protein extracts of the human pancreas with a fluorometric ß-secretase proteolytic activity assay. Immunoblot and immunohistochemistry with specific antibodies in paraffined sections were used to determine the human pancreatic cell types expressing BACEs. The intracellular localization of BACE1 and BACE2 was assessed by the immunocolocalization with specific intracellular markers (Na^+/K^+-ATPase, clathrin, insulin, Gm130, Tfrc) in MIN-6 cell line. To study the role of BACE on MIN-6 cells, we used a selective and fast cell-permeable substrate-based inhibitor designed from the ß-secretase cleavage sites (BI-II). Real time-PCR was used for *insulin* transcript quantification.
Results: High levels of BACE enzymatic activity were detected in protein extracts of human pancreatic islets and exocrine tissue. In human, BACE1 is expressed by both *a* and ß pancreatic cells population as well as in the exocrine tissue, while BACE2 is restricted to islet ß-cells. The intracellular localization of BACEs in MIN-6 cells showed BACE1 colocalization with insulin and BACE2 expression in clatrin-coated endocytic vesicles of the plasma membrane. When BACE pharmacological inhibition (BI-II) was performed for 24h in MIN-6 cells, BACE2 content in plasma membrane and clathrin-coated vesicles was significantly increased compared to control (from 4.8±0.8 to 9.7±2.6%, $p<0.05$ and from 14.0±2.6 to 26.2±1.9%, $p<0.001$ respectively), suggesting a BACE2 involvement in the processes of receptor-mediated endocytosis and recycling by clathrin-coated vesicles. The analysis of insulin internalization rate after glucose stimuli is reduced in BI-II treated MIN-6 cells compared to control (0.23±0.02 to 0.30±0.02%, $p<0.05$) despite of significantly increased levels of IRß protein extracts. The immunofluorescence

analysis showed a significant decrease in receptor expression at the plasma membrane (Na^+/K^+-ATPase) of treated cells compared to control (from 4.9±1.9 to 0.3±0.01%, $p<0.05$), with the receptor pool being retained in the Golgi apparatus (Gm130). Coherently with the impaired IRß trafficking to the plasma membrane, we also observed a 1,4 fold reduction in the transcriptional activity of the *insulin* promoter.
Conclusion: Our data suggest that the ß-secretes activity is needed for *insulin* expression in ß-cells and that the BACE2 is the enzyme involved. Thus, BACE2 is here presented as a potentially essential enzyme for ß-cell function.

Transgenic mice expressing an intestine-specific secretory protein, IBCAP, demonstrates pancreatic beta cell augmenting activity
T. Yokoo[1,2], K. Watanabe[3], K. Tada-Iida[3], H. Suzuki[3], H. Shimano[3], S.-E. Ishikawa[1], M. Kawakami[1], Y. Okazaki[2], N. Yamada[3], H. Toyoshima[1];
[1]Division of Endocrinology and Metabolism, Department of Medicine, Saitama Medical Center, Jichi Medical University, Saitama, [2]Division of Functional Genomics & Systems Medicine, Research Center for Genomic Medicine, Saitama Medical University, Hidaka, [3]Department of Internal Medicine, Metabolism and Endocrinology, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Japan.

Background and aims: Recent success with GLP-1 analogs and DPP IV inhibitory drugs in the clinical application for diabetic patients has highlighted the role of intestine as a hormone producing organ. Crucial roles of these hormones, including GLP-1, GIP and Ghrelin, in the control of energy metabolism and food intake, and their relation with the metabolic syndrome have been brought to worldwide attention. In the current studies, we aimed to search for secretory proteins expressed in the intestine.
Materials and methods: We have constructed and screened a mouse intestinal cDNA library to search for genes encoding secretory and membrane proteins, using the Oligo-cap Signal Sequence Trap (Oligo-cap SST) method developed in our laboratory. For CF266 functional analysis *in vivo*, we prepared the recombinant CF266 expressing adenovirus and we analyzed the phenotype of CF266 over-expression mice model.
Results: We have identified CF266 as a novel intestine-specific secretory protein using the Oligo-cap SST strategy. We demonstrated that CF266 had insulin secretion promoting effect, and furthermore, that adenovirus-mediated expression of CF266 in STZ-treated type 1 diabetes model mice improved the blood glucose level of the animal, and showed the increased pancreatic β-cells detected by the histological analysis. Here, we have developed transgenic (Tg) mice expressing CF266 under the control of CAG-promoter. Analyses of the Tg mice have shown marked increase of pancreatic islets, confirming our former findings with the STZ-induced diabetic mice treated with CF266 expressing adenovirus. Thus, we renamed CF266 as IBCAP; intestine-derived beta-cell augmenting promoter. Further analyses have shown that blood glucose concentration and OGTT of IBCAP Tg mice are relatively normal compared with the control mice. Therefore, IBCAP seems to have promoted the augmentation of islets which are functionally normal. We are now testing whether augmentation of the β-cell islets is due to inhibition of apoptosis or stimulation of proliferation.
Conclusion: Our findings will provide IBCAP as another potential therapeutic target for diabetes and pancreatic β-cell regeneration.

Increased phosphorylation of FOXO1 during glucocorticoid excess is not mediated by SGK1 (Serum glucocorticoid inducible kinase 1) in insulin secreting cells
G. Schulz-Raffelt[1], S. Berchtold[2], D. Michael[1], F. Ranta[1], H.-U. Häring[1], S. Ullrich[1];
[1]Internal Medicine IV and Clinical Chemistry, [2]Internal Medicine I, University of Tübingen, Germany.

Background and aims: The essential role of insulin receptor signalling including PI3K and PKB activation for sufficient insulin disposal is well documented. Previously, we demonstrated that glucocorticoids induce the expression of serum- and glucocorticoid-inducible kinase 1 (SGK1), an enzyme with 54 % identity in the catalytic domain with PKB and stimulated by insulin. SGK1 in parallel to PKB exerts anti-apoptotic effects in a variety of cells. Indeed, unlike glucocorticoids, transfection with SGK1 did not augment apoptotic cell death of insulin secreting INS-1E cells. The aim of the present study was to examine whether FOXO1, a PKB substrate, is regulated by SGK1 in cells under glucocorticoid excess.
Materials and methods: Insulin secreting INS-1E cells were treated with dexamethasone (dexa, 100 nM) to induce the endogenous expression of SGK1. SGK1 activity was selectively inhibited with a specific inhibitor (GSK650394) or by transient transfection with siRNA against SGK1. Alternatively, cells were transiently transfected with constitutive active or dominant negative hSGK1. Expression and phosphorylation of proteins were analyzed by Western blotting. Cellular distribution of immunostained proteins was examined using confocal microscopy.
Results: Treatment of the cells with dexa reduced phosphorylation of PKB, but paradoxically increased phoshorylation of FOXO1. The inhibition of PKB by Akti-1/2 abolished phosphorylation of FOXO1 in control cells. In dexa-treated cells FOXO1 phosphorylation was inhibited by Akti-1/2 but not by SGK1 inhibitor (up to 10 μM). In parallel, Akti-1/2 promoted nuclear translocation of FOXO1 while SGK1 inhibitor did not. Pretreatment of cells with siRNA against SGK1 inhibited the induction of SGK1 by dexa by 66 % at the mRNA level and by 80 % at the protein level. Although SGK1 protein level was reduced dexa treatment still increased FOXO1 phosphorylation. Furthermore, in cells transfected with either constitutive active or dominant negative hSGK1 phosphorylation of FOXO1 was unchanged.
Conclusion: These data suggest that the increased phosphorylation of FOXO1 observed after dexa-treatment is sensitive to PKB inhibition but does not depend on SGK1 in INS-1E cells.

PLCζ expressing in islet beta cells: does it express in sperm specifically?
H. Zheng[1], W. Wu[2];
[1]Endocrinology, Xinqiao Hospital, [2]Cardiothoracic Surgery, Southwest Hospital, Third Military Medical University, Chongqing, China.

Background and aims: Phospholipase C (PLC) is considered to modulate insulin secretion stimulated by diverse factors such as nutrients, hormone, neurotransmitter and ions. There are six established families of PLC termed β, γ, δ, ε, ζ andη, however, the role of each isoform in stimulated insulin secretion remains obscure. In this study, several isoforms of PLC which could express in pancreatic beta cell were identified. And the expression level of each isoform after stimulated by different factors was quantified in order to reveal the function of each isoform in insulin secretion.
Materials and methods: The expression levels of the isoforms of PLC in INS-1 cells (a rat insulinoma cell line) were semi-quantified by RT-PCR. In order to study on the role of each isoform in different factor-stimulated insulin secretion, glucose, L-aminoglutaminic acid (L-GLU), chloratum kalium (KCL), cholecystokinin-octopeptide (CCK8), and acetylcholine chloride were chosen as stimulating factors. INS-1cells were stimulated by the factors mentioned above respectively, and the mRNA level of each PLC isoform was semi-quantified by RT-PCR.
Results: Surprisingly, PLCζ, an isoform of PLC which was thought to express specifically in sperms was detected in INS-1 cell line and rat pancreatic tissue in our study. The expression of PLCδ, PLCβ, PLCγ and PLCη could also be detected in INS-1 cells except for PLCε. Many isoforms were induced when INS-1 cell line stimulated by different factors. PLCδ (1.97 folds), PLCβ and

PLCγ expressions on INS-1 cells were significantly up-regulated after stimulation with glucose (P<0.05); PLCβ (1.98 folds), PLCδ and PLCζ expressions on INS-1 cells were significantly up-regulated after stimulation with L-GLU (P<0.05); PLCη(1.89 folds), PLCδ, PLCγ and PLCζ expressions on INS-1 cells were significantly up-regulated after stimulation with KCL (P<0.05); PLCδ (2.54 folds), PLCγ and PLCη expressions on INS-1 cells were significantly up regulated (P<0.05) after stimulation with CCK8; And the expression of PLCδ was increased 1.84 folds when INS-1 cells were stimulated by acetylcholine chloride(P<0.05).
Conclusion: This is the first study to demonstrate that PLCζ expresses in islet beta cells. The expression of PLCδ was significantly increased while INS-1 cells were stimulated by glucose, CCK8 and acetylcholine chloride; The expression of PLCβ was significantly increased while INS-1 cells were stimulated by L-GLU; and the expression of PLCη was significantly increased while INS-1 cells were stimulated by KCL. Different isoforms of PLC were differentially expressed while INS-1 cells under different pressures, indicating that different stimulation factor stimulate INS-1 cell to secrete insulin through different isoforms of PLC.

PKCdelta modulates cell cycle progression and survival through the regulation of cytosolic-nuclear trafficking of p21 in insulin secreting INS-1E cells
F. Ranta, T. Theilig, J. Leveringhaus, H.-U. Häring, S. Ullrich;
Internal Medicine IV and Clinical Chemistry, University Hospital Tübingen, Germany.

Background and aims: The main cause for overt type 2 diabetes mellitus is decreased beta-cell mass due to increased apoptosis and reduced proliferation. Accumulating evidences suggest the involvement of PKCdelta in apoptotic signalling of beta-cells but little is known about the role of this kinase for proliferation. Regulation of cell cycle through PKCdelta-dependent modulation of p21 protein was described in several cell systems. $p21^{WAF1/CIP1}$ is an inhibitor of several cyclin-dependent kinases in the nucleus. It has been described that PKCdelta- and PKB-dependent phosphorylation of p21 affects its cytosolic-nuclear trafficking. In pancreatic beta-cells the role of p21 is still under debate. While the p21 KO mice have normal beta-cell mass and replication rate, the over-expression of p21 in beta-cells led to increased apoptosis but surprisingly conferred improved recovery from streptozotocin-induced diabetes. This study was undertaken to elucidate the role of PKCdelta and p21 for cell cycle progression and survival of beta-cell.
Materials and methods: INS-1E cells were stably infected with wild type (PKCdeltaWT) or kinase dead (PKCdeltaKN) PKCdelta using a retroviral system. Cell cycle was analysed after staining nuclear DNA with propidium iodide using fluorescence activated cell sorting (FACS). Proteins expression was assessed by Western blotting and their subcellular distribution by Western blotting after nuclear and cytosolic fractionation of cells or by confocal microscopy after immunostaining for the respective proteins. Apoptosis was quantified by TUNEL staining.
Results: PKCdeltaKN cells displayed reduced growth and increased apoptosis (7.8 %), while growth and apoptosis (4.5 %) of PKCdeltaWT cells were similar to those of control INS-1E cells (3.7 %). The analysis of cell cycle phases revealed that PKCdeltaKN cells have a strongly impaired G2/M transition accumulating in G2, whereas the cell cycle distribution pattern of PKCdeltaWT cells did not differ from control INS-1E cells. Further, 17.4 % of the PKCdeltaKN cells stained positive for the G2/M marker p-ser10-histone H3 but only 5.8 % of PKCdeltaWT and 8.3 % of control INS-1E cells were histone H3-positive. The G2 cell cycle regulatory protein cdc2 and the inhibitor p27 were expressed at similar levels in control, PKCdeltaWT and PKCdeltaKN cells, whereas p21 protein was reduced in PKCdeltaWT cells. The analysis of subcellular distribution showed extrusion of p21 from the nucleus in PKCdeltaWT cells. In control cells 8.1 % of nuclei and in PKCdeltaKN cells 24.2 % of nuclei stained positive for p21. Inhibition of the nuclear export machinery with leptomycin B neither induced nuclear accumulation of p21 in PKCdeltaWT cells nor augmented the accumulation of p21 in PKCdeltaKN nuclei.
Conclusion: These observations suggest that PKCdelta inhibits nuclear entrance of p21 and the cytosolic trapping of p21 sustains cell cycle progression. On the other hand, in PKCdeltaKN cells increased nuclear accumulation of p21 may lead to prolonged G2 phase and impaired cell cycle progression affecting cell growth and survival.

Knock-down of PI3K-C2α leads to increased proliferation of pancreatic beta cells
B. Leibiger, T. Moede, P.-O. Berggren, I.B. Leibiger;
Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: PI3K-C2α plays an important role in controlling cell survival via the intrinsic cell death pathway. Knock-down of PI3K-C2α protein levels led to a reduction in cell proliferation and viability in a number of cancer-derived cell lines. We have recently shown that PI3K-C2α generates $PI(3,4)P_2$ in beta cells and is involved in glucose-stimulated insulin release. Knock-down of PI3K-C2α levels leads to reduced PKBα activity, AS160 phosphorylation and glucokinase protein levels. The aim of this study was to evaluate the role of PI3K-C2α in beta cell proliferation and survival.
Materials and methods: MIN6 cells and primary mouse beta cells were treated with control siRNA or siRNA against PI3K-C2α. Knock-down of protein levels of PI3K-C2α was verified by Western blotting (80% knock-down). Proliferation in MIN6 cells was measured directly by counting the number of cells and by BrdU-incorporation. Apoptosis rate of MIN6 cells after treatment with either H_2O_2 or staurosporine was determined by triple staining with Hoechst 33342, propidium iodide (PI) and AlexaFluor488-annexinV, where AlexaFluor488-annexinV positive PI-negative stained cells were considered apoptotic. Cell proliferation of primary mouse beta cells was determined by BrdU-incorporation. Phosphorylation of PKB target proteins and Raf-1 in MIN6 cells was evaluated by Western blotting.
Results: To our surprise knock-down of PI3K-C2α did not lead to an inhibition of cell growth like in other cell lines, but to an increased cell proliferation. Cell count 120 h after siRNA transfection gave a 3.2 ± 0.12fold increase in cell number in PI3K-C2α siRNA-treated cells compared to control siRNA-treated MIN6 cells. BrdU incorporation was increased to 21.75 ± 2.54% in PI3K-C2α siRNA-treated MIN6 cells (9.38 ± 1.06% in control siRNA-treated cells) and to 1.67 ± 0.22% in primary mouse beta cells treated with PI3K-C2α siRNA (0.71 ± 0.067% in control siRNA-treated cells). Knock-down of PI3K-C2α led to a significant (p<0.05) protection against apoptosis induced by 20μM H_2O_2 (11.95 ± 1.86 % apoptotic cells in PI3K-C2α siRNA-treated MIN6 cells versus 24.19 ± 0.89 % in control siRNA-treated cells) or by 6μM staurosporine (24.89 ± 1.37 % apoptotic cells in PI3K-C2α siRNA-treated MIN6 cells versus 34.61% ± 2.42 % in control siRNA-treated cells). Since insulin-stimulated PKBα activity was diminished in PI3K-C2α siRNA-treated cells, we evaluated the phosphorylation of PKB target proteins (TSC2, GSK3β, FoxO1) in MIN6 cells after insulin stimulation. GSK3β Ser9-phosphorylation was not altered by PI3K-C2α-siRNA treatment. The increase of TSC2-Thr1462- and FoxO1-Ser256-phosphorylation after insulin stimulation was abolished by PI3K-C2α siRNA-treatment. Ser338-phosphorylation of Raf-1 was increased in PI3K-C2α siRNA-treated MIN6 cells after insulin stimulation (1.54 ± 0.12fold compared to control siRNA-treated cells). The observed changes in the phosphorylation status of TSC2 and FoxO1 are in line with diminished PKBα activation in response to insulin stimulation, but would lead to inhibition of cell growth, rather than to its stimulation. The increased phosphorylation of Raf-1, a kinase of the Ras/Raf-1/ERK cascade known to be involved in beta cell proliferation and protection against apoptosis, could explain the increased proliferation in PI3K-C2α siRNA-treated cells.
Conclusion: Knock-down of PI3K-C2α in pancreatic beta cells leads to increased cell proliferation by a pathway involving Raf-1 activation.

Focal adhesion remodelling is crucial for glucose-stimulated insulin secretion and involves activation of focal adhesion kinase and paxillin
D. Rondas, A. Tomas, P. Halban;
Genetic Medicine and Development, University of Geneva, Switzerland.

Background and aims: Despite the numerous studies on the mechanism of pancreatic beta cell insulin secretion, many aspects of the molecular machinery remain to be elucidated. Actin cytoskeleton remodelling is well known to be positively involved in glucose-stimulated insulin secretion (GSIS). We have observed glucose-stimulated changes at the beta cell surface that are similar to focal adhesion remodelling in cell migration. This led us to study the role of two key focal adhesion proteins, Focal Adhesion Kinase (FAK) and paxillin, in glucose-stimulated beta cell focal adhesion remodelling and insulin secretion.

Materials and methods: FACS-sorted rat primary beta cells were used unless stated otherwise. For immunofluorescence staining and protein phosphorylation, beta cells were incubated for 2h at 2.8 mM glucose followed by 16.7 mM glucose for up to 1h. siRNA was used to knockdown paxillin expression: cells were transfected (Lipofectamine 2000; 100nM siRNA) 3 days prior to testing GSIS [2h pre-incubation at 2.8 mM glucose; 1h 2.8 mM glucose (basal); 1h 16.7mM glucose (stimulated)]. Data are mean±SEM, n=3 independent experiments.
Results: In the basal state, FAK (Tyr-397) and paxillin (Tyr-118) were modestly phosphorylated and localised in few long filopodia at the basal cell surface. Stimulation for 20 min at high glucose resulted in increased phosphorylation of FAK and paxillin and cell spreading, with a 59±8% ($p<0.001$) increase in cell surface area vs. basal after 1h at high glucose. Within 20 min at 16.7 mM glucose there was appearance at the basal surface of numerous newly formed, shorter actin filopodial extensions, containing phosphorylated paxillin. Co-incubation with the L-type Ca^{2+} channel blocker, SR-7037 (10μM), completely inhibited this sequence of events, indicating requirement of increased cytosolic Ca^{2+}. Furthermore, knockdown of paxillin (45±2% decrease by western blot) decreased GSIS by an average of 61±4% ($p<0.05$) vs. control transfected with scramble RNAi. A 43±1% ($p<0.05$) decrease in GSIS was observed following pharmacological inhibition of glucose-induced phosphorylation of FAK Tyr-397 by compound Y15 in the MIN6B1 beta cell line; this was confirmed in a single preliminary experiment on primary rat beta cells.
Conclusions: We show here that glucose-stimulated spreading of beta cells coincides with the remodelling of filopodial extensions and phosphorylation of the two main focal adhesion proteins, FAK and paxillin. Additionally, GSIS was significantly decreased by paxillin knockdown and inhibition of FAK activation, showing for the first time that focal adhesion remodelling is a critical event in pancreatic beta cell function.

Novel aspects of female sex hormone estrogen in diabetes
R. Kumar[1], A. Balhuizen[1], A. Salehi[1], I. Lundquist[1], S. Amisten[2];
[1]Clinical Science, Lund University Malmo, Sweden, [2]Clinical Science, Oxford University, United Kingdom.

Background and aims: The lower prevalence of diabetes in females suggests that female sex steroids protect from β-cell injury. Consistent with this hypothesis, 17β-estradiol manifests antidiabetic actions in humans and rodents. Our recent findings show that the stimulatory action of 17β-estradiol on insulin secretion is mediated by the G protein coupled receptor 30 (GPR30), raising the prospect that antidiabetic action of 17β-estradiol might be due, in part, by an antiapoptotic effect on β-cells exerted through activation of GPR30.Therefore,the objective of this study was to identify expression of GPR30 in human pancreatic islets and to further clarify the role of GPR30 in pancreatic hormone secretion and beta cell survival.
Materials and methods: GPR30 expression was analyzed by confocal microscopy, Western blot and qRT-PCR in human pancreatic islets from female and male donors. Hormone secretion and cAMP content in islets were determined with RIA and apoptosis with the Annexin-V method.
Results: Confocal microscopy revealed GPR30 expression in alpha, beta and delta cells of pancreas. GPR30 mRNA and protein expression was markedly higher in female vs male islets ($p<0.01$). Dose-response studies of G-1 (a selective agonist of GPR30) vs 17β-estradiol in isolated islets at 12 mM glucose showed an almost similar pattern in potentiating insulin and suppressing glucagon and somatostatin secretion. The 17β-estradiol genomic receptor (ERα and ERβ) antagonist ICI-182,780 (Fulvestrant) or Acolbifene (EM-652) did neither influence the amplifying effects of G-1 or 17β-estradiol on cAMP content ($p<0.001$) nor insulin secretion from islets. Cytokine-induced (IL1β+TNFα+INFγ) apoptosis in islets, cultured for 24 h at 5 mmol/l glucose, was almost abolished by G-1 or 17β-estradiol treatment ($p<0.001$).These beneficial effects of G-1 or 17β-estradiol on pancreatic islets were not affected by either Fulvestrant or Acolbifene.
Conclusion: In view of these novel finding we suggest that drugs that could selectively modulate the activity of GPR30, represent a promising frontier in diabetes mellitus co-adjuvant therapy.

Polyamines and human pancreatic beta cells
L. Marselli[1], J. Thorne[2], M. Bugliani[1], A. Lena[1], M. Tancredi[1], K. Fujiwara[3], V. Gremigni[1], A. Sharma[2], G.C. Weir[2], P. Marchetti[1];
[1]University of Pisa, Italy, [2]Harvard University, Boston, USA, [3]Sojo University, Kumamoto, Japan.

Background and aims: Polyamines (PA, in particular putrescine, spermidine and spermine) are ubiquitous chemical entities that play an important role in cell function and turnover, as well as in the synthesis of proteins and nucleic acids. Aim of the study was to assess whether PA may be of importance in affecting beta-cells in non-diabetic subjects and type 2 diabetic individuals.
Materials and methods: Pancreatic tissue obtained from 17 type 2 diabetic subjects (T2DM; age: 67±9 years; M/F:11/6; BMI: 29±5 kg/m^2) and 15 non-diabetic controls (ND; age: 62±15 years; M/F:11/4; BMI: 26±2 kg/m^2) was studied. The presence of PA in beta-cells was assessed on electron microscopy by immunogold technique. Gene expression studies were performed with isolated islets or beta-cell enriched samples prepared by laser capture microdissection. Islets insulin secretion was determined in response to acute glucose stimulation after 24 h incubation with or without 2-difluoromethylornithine (DFMO, an inhibitor of ornithine decarboxylase I, 5 mM), putrescine (50 μM) and spermidine (50 μM), alone or in combination.
Results: Putrescine and spermine were detected in beta-cells from ND and T2DM by electron microscopy. Localization was mainly in the cytoplasm for putrescine and in both the cytoplasm and the nucleus for spermine. Microarray analyses showed that ornithine decarboxylase I (key enzyme in PA synthesis) was lower in beta-cells ($p<0.001$) and islets ($p=0.03$) from T2DM. Data were confirmed by qPCR studies, which detected also a lower expression of arginase II in diabetic samples. DFMO caused a decrease ($p<0.05$) of glucose-stimulated insulin release (-32 ± 9.5%); the same was observed in presence of spermidine (-48 ± 32%, $p=0.05$). Putrescine prevented the inhibitory effect of spermidine.
Conclusion: This study shows that 1) PA are present in human beta-cells; 2) PA biosynthesis pathway may be different in type 2 diabetic beta-cells; and 3) PA may have a role in insulin secretion.

Insulin secretion is affected by disruption of mini-P-glycoprotein
D.-Q. Li, Y.-Z. Tang, S.-Y. Meng, Q. Ding, D.-M. Yu;
Key Lab of Hormones and Development (Health Ministry of China), Tianjin Metabolic Diseases Hospital, China.

Background and aims: A 65-kDa mdr1-like protein, which exhibited biological functions similar to the sulfonylurea receptor, had been preliminary identified as a mini-P-glycoprotein in rat islets. In this study, the mini-P-glycoprotein was down-regulated by siRNA technique and effects on biphasic insulin secretion were determined.
Materials and methods: Stealth ™ / siRNA duplex oligoribonucleotides (Invitrogen) was designed to silence the *abcb1b* gene (*mdr1,* encoding P-glycoprotein). Stealth RNAi Negative Control Duplexes was severed as negative control. The silencing effects were determined by fluorescence microscopy, quantitative PCR and Western blot. Biphasic insulin secretion was investigated in rat islet batch incubations in three different groups: silencing, negative control and blank (without oligoribonuccleotides). In parallel, apoptosis in the rat islets in the respective groups was also evaluated.
Results: After 48 hours incubation, more than 95% of the islets were visibly transected. The expression of the *abcb1b* mRNA was decreased significantly by the siRNA but not the *abcb1a* mRNA, which were used as technique control ($P<0.001$ and $P=0.815$, respectively). Mini-P-glycoprotein expression was detected using the specific antibody C219 and was reduced by more than 80%. Biphasic insulin release was dramatically reduced by the silencer, both in the first and second phase, when compared with the negative control or the blank groups ($P<0.05$ and 0.001; n=10 for all the groups, Fig.1). Apoptosis was induced when islets were cultured in high glucose (16.7mmol/L) culture medium for 48 hours compared to those in normal culture medium. Up-regulated expression of *casp3* and *bax* were detected in the silencing group ($P<0.01$ and 0.001 *vs* the negative control group or blank group), while *Bcl-2* expression was down-regulated ($P<0.001$). However, the expressions of *casp3*, *bax* and *bcl-2* were not influenced by the silencing of the mini-P-glycoprotein.
Conclusion: The mini-P-glycoprotein may contribute to biphasic insulin secretion. Apoptosis of rat islets is not induced by the disruption of the mini-

P-glycoprotein. It has been suggested that the mini-P-glycoprotein might function as one of the regulatory proteins to the chloride transport protein 3 to mediate insulin granules acidification and priming. Further investigation need to be done to evaluate the underlying mechanisms.

CART is overexpressed in beta cells of diabetic mice to improve insulin secretion

M. Riva, N. Wierup;
Lund University Diabetes Centre, Lund University, Sweden.

Background and aims: Cocaine- and amphetamine-regulated transcript (CART) is a novel islet regulatory peptide. CART null mutant mice exhibit impaired glucose tolerance due to islet dysfunction, and diminished expression of PDX-1. CART regulates islet hormone secretion, including augmenting GLP-1-enhanced glucose-stimulated insulin secretion (GSIS) in vitro. Moreover, CART is upregulated in the beta cells of Type-2 diabetic (T2D) rats. Although the effects of exogenously added CART on the beta cell are established, the role of endogenous beta cell CART is unknown. Furthermore, CART expression in islets of T2D mouse models has not been studied. We studied islet expression of CART in diabetic db/db and ob/ob mice using immunocytochemistry and in situ hybridization. To mimic the situation in beta cells of T2D models we overexpressed CART in clonal INS-1 (832/13) beta cells using adenovirus and measured: 1) Insulin secretion stimulated with glucose (GSIS) and an array of secretagogues. 2) Gene expression of key genes related to insulin secretion and beta cell function. 3) Regulation of CART gene and protein levels after culture in different glucose concentrations.
Materials and methods: Male db/db, ob/ob, and C57BL/6 mice were used. CART expression was examined with immunocytochemistry, in situ hybridization, immunogold labeling and transmission electron microscopy (TEM), real-time PCR and Western blot. preproCART was overexpressed in INS-1 (832/13) cells and insulin secretion after 1h static incubations was analyzed using RIA. GFP-adenovirus was used as negative control.
Results: CART was robustly upregulated in beta cells of both db/db and ob/ob mice, compared to control mice. Immunogold labeling for CART revealed that CART was located to the beta cell granules. CART overexpression in INS-1 (832/13) cells was verified using real-time PCR and western blot. Overexpression of CART resulted in a moderate and dose-dependent augmentation of GSIS. Furthermore, overexpression of CART resulted in increased forskolin-enhanced GSIS. On the other hand, overexpression of CART was without effect on GSIS in the presence of 35mM KCl. Moreover, overexpression of CART elevated mRNA expression levels of insulin, PDX-1 and syntaxin 1A. On the other hand, CART had no effect on the mRNA expression levels of GLUT2, Kir6.2, or Munc-18-1. Culturing CART-overexpressing cells for 24 h in 16.7 mM glucose provoked a decrease in CART mRNA expression and an upregulation of CART protein levels, compared to culture in 3 mM and 11.1 mM glucose.
Conclusion: We conclude that CART is upregulated in the beta cells of diabetic mice and that beta cell CART is regulated by glucose. Furthermore CART stimulates the triggering pathway of insulin secretion, as well as expression of insulin and genes important for beta cell function and insulin exocytosis. Together these data suggest that CART is upregulated in beta cells of T2D animals to improve insulin secretion and gene expression. The potential for CART-based substances for future treatment of T2D remains to be established.

Stimulation of 5-HT1a receptor decreased insulin secretion in islets of Langerhans from mice and humans

H. Bennet[1], C.L.F. Nagorny[2], N. Wierup[3,4], M. Dekker-Nitert[2], Å. Lernmark[1], M. Fex[1];
[1]The unit of diabetes and celiac disease, Clinical Science, Malmö, [2]Clinical science, Malmö, [3]Experimental Medical Science, Lund, [4]Clinical Science, Malmö, Sweden.

Background and aims: 5-Hydroxytryptamine, also known as serotonin activates the receptors 5-HT1a (5-hydroxy-tryptophane receptor 1a) and 5-HT1a (5-hydroxy-tryptophane receptor 2b). 5-HT1a and 5-HT2b are both G-protein coupled receptors, 5-HT1a couples negatively to adenylate cyclase while 5-HT2b activates Gq and activates the phospholipase C pathway. The

G-protein activation result in different cellular events by two distinct intracellular pathways, affecting the levels of calcium in the cell. Both receptors have previously been found in islets of Langerhans from rodents. In addition, serotonin has been shown to be present in islet cells from several different animal species. As both receptors and amines are present, serotonin may potentially regulate hormone secretion from islets of Langerhans. In the previous studies we have shown that a selective 5-HT2b agonist alpha-Methyl serotonin potentiates glucose stimulated insulin secretion from INS-1 cells, mouse, and human islets of Langerhans from healthy individuals. This has now been further investigated in human islets of Langerhans from type 2 diabetic individuals. We have also investigated the effect of a 5-HT1a receptor agonist on insulin secretion in islets of Langerhans from both mouse and humans.
Material and methods: We used RT PCR and sequence specific primers to detected expression of the receptors in the beta-cell line (INS 832/13) and in islets of Langerhans. Immuno-histochemical analysis was used to detect the receptors at the protein level in rodent islet and human islets. Islets from mouse were isolated by standard collagenase digestion. Human and mice islets were incubated with glucose and Buspirone or alpha-methyl serotonin at 37 ºC for 1h and assayed for insulin secretion. Insulin was measured with insulin ELISA specialized for mice and human islets.
Results: 5-HT2b mRNA was found in the 832/13 cells. We also found both 5-HT1a and 5-HT2b to be expressed in rodent and human islets, at both mRNA and protein level. Interestingly, 5-HT receptors in islets were localized in two different cell types in the islets. In rodent islets, 5-HT2b was predominantly expressed in beta-cells while 5-HT1a was more abundant in the alpha-cells. In human, islets the situation was reversed. While stimulation with alpha-methyl serotonin potentiated glucose stimulated insulin secretion in human islets of Langerhans from type 2 diabetic individuals. Buspirone showed a significant decrease of insulin secretion at stimulatory glucose concentrations in mouse and human islets.
Conclusion: Our results strongly suggest that serotonin and the 5-HT1a and 2b receptors regulate insulin secretion. As both 5-HT1a and 5-HT2b are expressed in rodent and human islets and activate two very distinct cellular pathways, these receptors may in fact modulate secretion from both alpha and beta-cells. In conclusion, pathways of serotonin and its receptors may provide exciting new insight in the regulation of islet hormone secretion.

Nesfatin-1 stimulates insulin secretion, inhibits glucagon secretion and is expressed in human and rodent beta cells
U. Voss, M. Riva, M.N. Dekker Nitert, C. Ling, A. Lindqvist, N. Wierup;
Lund University Diabetes Centre, Lund University, Sweden.

Background and aims: Nesfatin-1 is a recently discovered regulatory peptide with anorexigenic properties. The peptide is the N-terminal part of nucleobindin 2 (NUCB2) and is highly expressed in brain areas known to regulate feeding behaviour. Outside the brain, nesfatin-1 expression has been reported in gastric endocrine cells. We studied the possibility of nesfatin-1 expression in human, rat, and mouse islets of Langerhans using immunocytochemistry and in situ hybridization. Furthermore, we investigated potential influence of nesfatin-1 on secretion of insulin and glucagon. Effects of nesfatin-1 on Ca2+ and cAMP levels was studied in INS-1 (832/32) cells, and nesfatin-1 gene expression in human islets under glucolipotoxic conditions was examined using affymetrix.
Materials and methods: Nesfatin-1 expression was examined using immunocytochemistry, in situ hybridization. Insulin and glucagon secretion after 1h static incubations of isolated mouse islets was analyzed with RIA or ELISA. Ca2+ fluorescence and cAMP was studied in INS-1 (832/13) cells.
Results: Nesfatin-1 was found to be highly expressed in human islets. Double staining for nesfatin-1 and the main islet hormones revealed that nesfatin-1 was exclusively expressed in human beta cells. Nesfatin-1 was also highly expressed in rat and mouse islets. The majority of all nesfatin-1 expressing cells were beta cells in rat and mouse. In the rat a minor subpopulation of the alpha cells harbored also nesfatin-1. Importantly, in situ hybridization and microarray for NUCB2 mRNA confirmed the immunocytochemical data. Studies in isolated mouse islets revealed that nesfatin-1 stimulates insulin secretion at both low (2.8 mM and 5.5mM, $p<0.001$) and high glucose concentrations (11.1. mM, $p<0.001$). Nesfatin-1 also augmented forskolin-enhanced glucose-stimulated insulin secretion (GSIS) ($p<0.01$), but not GSIS potentiated by carbachol or KCl. In addition, nesfatin-1 lowered secretion of glucagon at low (2.8 and 5.5 mM) glucose ($p<0.001$), but not at high (11.1 mM) glucose. Further, nesfatin-1 caused an increase in Ca2+ influx, but decreased cAMP in INS-1 (832/13) cells. Moreover, affymetric analysis revealed that NUCB2 mRNA was moderately upregulated under glucolipotoxic conditions in human islets.
Conclusion: Together our data suggest that nesfatin-1 is a novel glucose-lowering peptide in human and rodent islets. In view of these data, stimulation of the nesfatin-1 pathway could be a new treatment strategy for Type 2 diabetes.

Expression of Bombesin Receptor Subtype-3 (BRS-3) in islets from different species and its role in the regulation of insulin secretion and glucose homeostasis
Y.-P. Zhou, Y. Feng, J. Xiao, J. Gorski, J.M. Metzger, X. Guan, L. Lin, A.D. Howard, M. Reitman, N.A. Thornberry, B.B. Zhang;
Metabolic Disorders, Merck Research Laboratories, Rahway, USA.

Background and aims: Bombesin-like peptides, such as bombesin and gastrin-releasing peptide, are known to promote insulin secretion and possibly β-cell proliferation. The biological functions of these peptides are mediated by a family of G-protein coupled receptors. The expression and roles of those receptors in pancreatic islets have not been fully investigated. Here we study the physiology of Bombesin Receptor Subtype-3 (BRS-3) in islets from various species, as it has recently been shown to be involved in the regulation of energy homeostasis and BRS-3 knockout mice manifest age-dependent obesity and reduced islet size.
Materials and methods: TaqMan analysis was used to measure mRNA levels. siRNA-mediated BRS-3 silencing, whole body Brs-3 knockout and BRS-3 specific agonist or antagonist were used to study the effects of BRS-3 on insulin secretion in mouse and human islets, and glucose tolerance in mice.
Results: Utilizing quantitative PCR, we observed high levels of BRS-3 mRNA in human, dog, and mouse (but not rat) pancreatic islets. Silencing BRS-3 with siRNA or pharmacological blockade with a BRS-3 antagonist, Bantag-1, reduced glucose stimulated insulin secretion (GSIS) in the rat INS-1 832/3 cells. In contrast, activation of the receptor with Bag-1, a potent, selective BRS-3 agonist, increased GSIS in the rat insulinoma cell line. The acute effects of Bag-1 on GSIS in isolated islets and on blood glucose *in vivo* during oral glucose tolerance tests (OGTT) were examined. Bag-1 significantly enhanced GSIS in isolated islets and reduced OGTT glucose levels in wild-type, but not *Brs3* knockout mice. BRS-3 agonists also promoted GSIS in human islets isolated from a non-diabetic subject and from a patient with type 2 diabetes. These results reveal a role for BRS-3 in islet physiology, with agonism directly promoting GSIS.
Conclusion: In addition to its potential role in the regulation of body weight and energy homeostasis, BRS-3 may also regulate glucose homeostasis. Modulation of BRS-3 represents a potential new mechanism for glycemic control in type 2 diabetic patients.

p42/44 MAPK activation is required for receptor-operated stimulation of insulin release
J.E. Bowe, A. Chander, S.J. Persaud, P.M. Jones;
King's College London, United Kingdom.

Background and aims: We have previously shown that activation of the receptors GPR54 and CaR, by kisspeptin and the CaR agonist A568 respectively, potentiates glucose-induced insulin release via a p42/44 MAPK dependent pathway. The present study aimed to further examine the role of p42/44 MAPKs in receptor-operated potentiation of insulin release.
Materials and methods: Mouse islets were incubated for 1hr in a physiological salt solution and insulin release was measured by radioimmunoassay. Activation of p42/44 MAPK was measured by western blotting for phospho-MAPK relative to total MAPK immunoreactivity.
Results: Both the CaR agonist A568 (10μM) and kisspeptin (1μM) caused a significant potentiation of insulin secretion (214±26% and 182±19% basal respectively, $n=9$, $p<0.05$) at 20mM glucose. The stimulatory effects of both A568 and kisspeptin on insulin secretion were significantly blocked by the presence of the p42/44 MAPK inhibitor PD098059 (50μM; 131±12% and 109±8% basal respectively, $p<0.05$ versus absence of PD098059). However, whilst the acetyl choline analogue carbachol (500μM) also significantly potentiated glucose-induced insulin release (287±21% basal, $n=9$, $p<0.05$), the

presence of PD098059 had no effect. Furthermore, whilst activation of p42/44 MAPK was enhanced by incubation (5 min, 37°C) in the presence of stimulatory glucose levels, kisspeptin (1μM) had no effect on MAPK activation. A568 caused an increase in p42/44 MAPK activation at 2mM glucose, but had no effect at 20mM glucose. Finally islets were incubated in the presence of okadaic acid and sodium pervanadate in order to inhibit the dephosphorylation of p42/44 MAPK. Whilst neither kisspeptin nor A568 significantly affect insulin release from islets at sub-stimulatory glucose concentrations under normal conditions, in the presence of okadaic acid and sodium pervanadate (10μM and 100μM respectively) both kisspeptin and A568 caused a significant increase in insulin release from islets incubated at 2mM glucose (381±52% and 456±39% basal respectively, n=9, p<0.05).
Conclusion: These observations suggest that p42/44 MAPK activation may play a permissive role in the potentiation of glucose-induced insulin secretion by some receptor operated agonists such as kisspeptin and A568.

***In vitro* functions of pancreatic pseudoislets**
R.A. Zuellig, R.E. Locher, G.A. Spinas, R. Lehmann;
Division of Endocrinology, Diabetes and Clinical Nutrition, University Hospital Zurich, Switzerland.

Background and aims: Recently it was shown, that transplantation of small islets results in a better outcome than transplantation of large islets. Small islets can be produced in vitro by dissociating islets of all sizes in single cells and reaggregating the dispersed islet cells into pseudoislets of defined small sizes by the hanging drop method. We describe an alternative method to produce pseudoislets of different sizes in micro-well plates and analyse their morphology and in vitro function.
Materials and methods: Islets were dissociated into single cells by trypsin/EDTA treatment. The cells are seeded at defined densities into hanging-drops (HD) or especially designed micro-well plates. Plates of four different types of plastics were used: two types of polycarbonate (PC and NO), one polystyrene (PS) and one cyclic olefin copolymer (TO). Islets and seeded islet cells were cultivated for 7-14days and the resulting pseudoislets analysed in terms of morphology and glucose-stimulated-insulin-secretion (GSIS).
Results: Dissociated islet cells reaggregated to pseudoislets in micro-well plates. There was no significant difference in pseudoislet size between the different plastics. Pseudoislets originating from 300 seeded cells have an average diameter of (in micrometer) NO 60.9±15.4 n=15, PC 62.7±20.7 n=14, PS 70.7±17.7 n=9, TO 65.4±14.1 n=18; NO-PS p=0.19. The diameter of pseudoislets is approximately proportional to the numbers of cells seeded (to the power of 0.33), for NO with 600 cells 76.4±17.2 n=6. Pseudoislets from micro-well plates are smaller and have a larger variation in diameter as compared to HD-pseudoislets with 300 cells 93.1±6.1 n=4, HD with 750 cells 135.5±4.9 n=4, with 1500 cells 180.6±5.0 n=4. GSIS was similar for islets from micro-well plates and HD (basal 0.1 - 0.2, stimulated 1.2 - 1.5 fmol insulin/IEQ/min). In contrast to HD-pseudoislets derived from rat islets, GSIS was not increased in human pseudoislets (HD or micro-well plates). Human pseudoislets however exhibited an improved first phase insulin secretion (300cells per pseudoislet 1.94±0.5 fold steady state second phase, n=32; 600 cells per pseudoislet 1.95±0.15 n=5) compared to intact islets (1.31±0.33 n=57; p<0.005) whereas in rat pseudo- and intact islets there was no clear first phase insulin secretion.
Conclusion: The newly developed micro-well plates offer the possibility to produce large numbers of pseudoislets of similar quality as compared to the hanging-drop method. Small human pseudoislets exhibit an equal or improved insulin secretion as compared to intact islets. The true advantage of small pseudoislets in transplantation due to smaller size and better diffusion properties has to be proven in a large animal model.

Pharmacological effects on insulin release in a mathematical model of human beta cells
M.G. Pedersen;
Islet cell exocytosis, Lund University Diabetes Centre, Malmoe, Sweden.

Background and aims: Beta-cells use electrical activity to transduce changes in plasma glucose to calcium-triggered exocytosis and insulin secretion. Using a mathematical model based on recent electrophysiological characterizations of human beta-cells, the effect of a range of pharmacological interventions on patterns of electrical activity and exocytosis was investigated.
Materials and methods: A mathematical model based on high quality data from human beta-cells has been developed. The model is formulated as a set of ordinary differential equations, and describes voltage-gated K- and Na-channels, as well as T-, P/Q- and L-type Ca-channels. In addition, a background leak current, and ATP-sensitive K(ATP) and Ca-activated BK-potassium channels are also included. Exocytosis evoked by calcium currents through different types of Ca-channels is modeled. Numerical simulations corresponding to pharmacological interventions were performed.
Results: The model reproduces satisfactorily electrical patterns in response to blockage of various ion channels. The central role of K(ATP)-channels is shown, and electrical activity is a result of K(ATP)-channel closing by glucose or tolbutamide. For K(ATP)-conductance larger than ~0.02 nS/pF the model is silent and hyperpolarized, while it shows spiking activity for smaller K(ATP)-conductances, which results in exocytosis. A role for sodium and calcium channel activation for the upstroke, and activation of potassium channels for the downstroke of action potentials is found by simulating ion channels blockage. In the presence of K-channel blockers such as TEA, inactivation of Ca-channels is responsible for repolarization. It is shown that P/Q-types calcium currents are crucial for evoked exocytosis, and that the result on insulin secretion of modification of other channels is transduced mainly by changes in electrical activity and P/Q-type Ca-currents. Modifying a leak current is shown to be a possible strategy for enhancing insulin secretion.
Conclusion: A mathematical model of electrical activity in human beta-cells is shown to predict the effects of ion channel modulating drugs. It is shown to be useful for hypothesis testing and prediction of the effect of ion channel modulation on electrical activity and insulin secretion.

Developing a mathematical model of the mechanism by which alanine enhances glucose-stimulated insulin secretion
M. Salvucci[1], Z. Neufeld[2], P. Newsholme[1];
[1]School of Biomolecular and Biomedical Science (SBBS), Ireland, [2]Complex & Adaptive Systems Laboratory (CASL), University College Dublin (UCD), Dublin, Ireland.

Background and aims: Pancreatic beta-cells play a key role in the glucose homeostasis, secreting insulin in response to blood nutrient fluctuations. This is due to a complex relationship between metabolism and insulin secretion which comprises both triggering (ATP and Ca^{2+} dependent) and amplifying (mitochondrial metabolite dependent) pathways of insulin secretion. Specific amino acids can modulate beta-cells function and thus acutely and chronically regulate insulin secretion through different mechanisms of action. Alanine is known to acutely stimulate insulin secretion alone or synergistically enhance glucose-stimulated insulin secretion (GSIS) both *in vivo* and *in vitro*. This study has attempted to develop a mathematical model, validated against wet lab experimental results, of the role played by the amino acid alanine in enhancing glucose-stimulated insulin secretion in pancreatic beta-cells.
Materials and methods: A simplified kinetic model of the glucose-stimulated insulin secretion in pancreatic beta-cells which takes into account glycolysis, Krebs cycle, NADH shuttles and glutamate and alanine transaminase was built. The model's input is made up of two nutrient components: glucose and alanine, while the output is constituted by NADH, ATP and glutamate. Experimental work was carried out on a functional clonal insulin-secreting cell line (BRIN- BD11). BRIN-BD11 cells were cultured for 48h prior to experiments, starved for 40 minutes at basal glucose level (1.1 mM) and then stimulated with different concentrations of only glucose (1.1, 5, 16.7, 30 mM), only alanine (10 mM) and their combinations. Samples were collected before and 10, 20, 60 minutes after administration of the stimulus. Samples were assayed for consumption and production of the key components of the mathematical model: glucose, lactate, ATP and insulin.
Results: Both glucose consumption and lactate production showed a dose-dependent increase which was significantly enhanced by addition of 10 mM alanine (p<0.001 and p<0.05, respectively at both 16.7 mM and 30 mM glucose). The kinetic of ATP production following stimulation over a 60 minutes period revealed that different stimulatory conditions can affect not only the magnitude of response, but also the kinetic mechanism of release. All stimulatory conditions showed an increase in ATP release over the first 20 minutes, subsequently ATP content reached a steady state and markedly decreased after 60 min incubation only in presence of alanine. Acute insulin secretion

was biphasic and concentration dependent with respect to glucose: increasing glucose concentration from 1.1 to 30 mM increased insulin secretion by 32% from 1.12 ng/mg protein/20 min to 1.48 ng/mg protein/20min. The addition of 10 mM alanine significantly increased ($p<0.05$) glucose stimulated insulin secretion by 1.8-2.3 fold after 20 minutes incubation. Administration of 10 mM alanine exhibited a strong insulin release (1.39 ng/mg protein/ 20 min).
Conclusion: These results highlight the synergistic effect of Alanine in enhancing glucose metabolism. Alanine metabolism may increase ATP release increasing insulin secretion through the K^+ ATP-dependent pathway. Alanine oxidation may also result in generation of glutamate, a putative messenger in insulin secretion, which may account for increased insulin release despite a lower ATP content.

The membrane potential response is altered in pancreatic beta cells chronically exposed to high glucose

I. Göhring[1], T. Köck[1], H. Mulder[1], D. Nicholls[2,1];
[1]Unit of Molecular Metabolism, Lund University Diabetes Centre, Malmö, Sweden, [2]Buck Institute for Age Research, Novato, USA.

Background and aims: Fuel-stimulated insulin secretion is coupled to increased cellular metabolic activity and consequently an increase of the ATP/ADP ratio, thereby leading to plasma membrane depolarisation and exocytosis. Any disturbance of the metabolic processing of fuels, such as glucose, particularly in mitochondria, may consequently affect the secretory process. Frequent episodes of severe hyperglycaemia are observed during the onset of diabetes and characterise poorly- or un-controlled Type 2 Diabetes. These elevated glucose levels lead to beta-cell desensitisation, and ultimately impaired beta-cell function. It is therefore of great interest to detect potential disturbances of normal fuel-stimulated plasma membrane changes as a result of chronic exposure to elevated glucose levels.
Materials and methods: INS-1 832/13 cells were cultured in either 2.8 mM or 16.7 mM glucose for 48 h. All cells were then starved for 2 h in buffer containing 2.8 mM glucose, after which recordings of the plasma membrane potential of a monolayer of cells, using a proprietary fluorescent anion and confocal microscopy were performed at 16.7 mM glucose with subsequent additions of 1 μg/ml oligomycin and 25 mM KCl. Insulin secretion was determined by radioimmunoassay.
Results: After 48 h culture in 16.7 mM glucose, glucose-stimulated insulin secretion was significantly ($p<0.05$) suppressed in INS-1 832/13 cells (15.32 ± 1.6 ng/mg/h) in comparison to cells cultured at 2.8 mM glucose (41.43 ± 8.13 ng/mg/h). Concurring, chronic high glucose levels altered the plasma membrane depolarisation response. Recordings of membrane potential activities of cells cultured at 2.8 mM glucose for 48 h showed complete hyperpolarisation before glucose stimulation (-79.5 ± 1.6 mV). Following addition of 16.7 mM glucose a mean depolarisation of all cells measured was recorded (-58.1 ± 0.4 mV) and individual cells produced rhythmic action potentials bursts, acquired in real time as oscillations in fluorescence intensity. By inhibiting the mitochondrial ATP synthase, oligomycin hyperpolarised the plasma membrane potential to basal values while high KCl produced a maximum membrane depolarisation of -41.6 ± 0.1 mV. In contrast, cells chronically cultured at 16.7 mM glucose produced rhythmic bursts of action potentials after the starvation period even before high glucose stimulation. The basal membrane potential recorded was higher (-72.1 ± 0.6 mV) than in cells cultured at 2.8 mM glucose. In addition, the mean depolarisation response of the chronic high glucose-treated cells was suppressed (-62.7 ± 0.3 mV) after anew stimulation with high glucose.
Conclusion: While cells kept at low glucose responded to stimulatory glucose concentrations with elevated plasma membrane depolarisation and stimulation-induced action potential bursts, in cells under chronic high glucose conditions this depolarisation response was greatly diminished. However, action potential bursts were recorded independent of glucose stimulation due to the inability of glucose-desensitised cells to fully hyperpolarise. We suggest that, as a consequence of chronic fuel overload, multiple cellular alterations, including changed glucose metabolism, contribute to a disturbance in the fuel-dependent coordination and regulation of plasma membrane potential changes and therefore the failure of beta-cells to secrete insulin.

555

Paradoxical membrane repolarisation during onset of insulin secretion

M. Willenborg[1], S. Denicke[2], H. Ghaly[1], U. Panten[1], I. Rustenbeck[1];
[1]Institute of Pharmacology and Toxicology, [2]Institute of Physical Chemistry, University of Braunschweig, Germany.

Background and aims: Plasma membrane depolarization (typically by K_{ATP} channel closure), activation of voltage-dependent Ca^{2+} channels and Ca^{2+} influx are regarded as indispensable for the initiation of stimulated insulin secretion. In addition to this "triggering pathway" nutrient secretagogues like glucose or ketoisocaproic acid (KIC) activate an "amplifying pathway" not involving depolarization and Ca^{2+} influx. The metabolic amplification can be demonstrated by a pretreatment with a maximal sulfonylurea concentration, then adding a stimulatory concentration of a nutrient secretagogue. Surpris-

ingly, we found the addition of nutrients to be related to a repolarization, thus abolishing the triggering signal which is believed to be necessary for the nutrient amplification to exert its effect.
Materials and methods: The plasma membrane potential of normal mouse beta cells was measured in the perforated patch mode of patch-clamp technique. The cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) as indicated by Fura and the NAD(P)H autofluorescence was measured by microfluorimetry of single perifused islets. NAD(P)H autofluorescence lifetime was determined by 2 photon excitation imaging. Insulin secretion was measured by batch perifusion and ELISA of the fractionated effluate.
Results: In the absence of any nutrient 2.7 μM glipizide depolarized the plasma membrane to a plateau of -45.5 ± 3.0 mV with superimposed action potentials peaking at -24.4 ± 4.0 mV (n=5). After application of 30 mM glucose or 10 mM KIC the membrane completely repolarized ($ -68.4 ± 2.1 mV) within 150 s (glucose) or 80 s (KIC). The repolarization phase lasted for 5.5 ± 2.0 minutes (glucose) and 6.8 ± 2.9 minutes (KIC) and then abruptly, the depolarization reappeared with the same characteristics. Concurrent with the depolarization by K_{ATP} channel closure, glipizide increased the $[Ca^{2+}]_i$, which remained elevated until the addition of nutrients. Both with glucose and with KIC the repolarization coincided with a biphasic decrease of the $[Ca^{2+}]_i$ down to values which existed before the exposure to glipizide (n = 4 each). While the elevated $[Ca^{2+}]_i$ completely recovered within 10 minutes in the case of glucose, there was only a partial recovery of $[Ca^{2+}]_i$ in the presence of KIC. Under the same conditions 10 mM KIC induced a strong increase of the secretion rate (by more than 10fold within 10 min), which remained elevated for more than 30 min. In contrast, 30 mM glucose was unable to further elevate the secretion rate established by glipizide in the absence of nutrients. Both glucose and KIC elevated the NAD(P)H autofluorescence of perifused islets, the relation between the increase by glucose and that by KIC was the same as in the absence of glipizide. Since both components of NAD(P)H fluorescence lifetime were left unchanged, both glucose and KIC induce a real increase of the mass of NAD(P)H and not a change in fluorescence properties.
Conclusion: Apparently glucose and KIC differ in their mechanisms of metabolic amplification. The onset of a strong and lasting secretory response to KIC does not necessarily require the presence of a depolarized plasma membrane and an increased $[Ca^{2+}]_i$.

In situ electrophysiological examination of alpha cells in type 1 diabetes revealing the cellular basis of glucagon hypersecretion
Y.-C. Huang[1], M. Rupnik[2], P.L. Herrera[3], P. Gilon[4], H.Y. Gaisano[5];
[1]Medical Science, University of Toronto, Canada, [2]University of Maribor, Slovenia, [3]University of Geneva, Geneva, Switzerland, [4]University of Louvain, Brussels, Belgium, [5]University of Toronto, Canada.

Background and aims: The cellular properties of α cells in type 1 diabetes (T1D) are unknown. This is because T1D autoimmune destruction of β cells causes the islet mass to shrink in size rendering islet isolation and dispersion not technically feasible; and consequently electrophysiological characterization of islet cells to reveal the underling mechanisms explaining the distorted glucagon secretion in T1D could not be done. We employed GluCre-ROSA26-YFP (GYY) mice, which expresses YFP in pancreatic α cells. Along with our newly developed pancreas slice preparation whereby α cell and its precise secretory physiology within intact pancreatic tissue can be examined by patch clamp technique, unperturbed by conventional islet isolation and dispersion procedures, we are able to reliably localize and directly examine α cells electrophysiological properties *in situ* in health and T1D. We hypothesize that T1D α cells possess perturbed ion channels properties which contribute to hyperglucagonemia in early stage of T1D.
Materials and methods: GYY mice were treated with streptozotocin (STZ) to induce T1D. IPGTT and radioimmunoassay (RIA) were performed to confirm diabetes phenotype. Pancreas slices were prepared from these mice to directly examine α cells ion channel properties in healthy and diseased islets by patch clamp technique. The identities of patched-cells were further confirmed by infusing fluoresecent marker (biocytin) during patching, showing its co-localization with YFP by confocal microscopy.
Results: Normal GYY mice α cells in slices revealed identical electrophysiological features to those of their background C57/BL6 mice we previously characterized. These α cells are equipped with readily-activated A-type I_K, voltage-gated I_{Na}, small size, low resting conductance, and inducible H/LVA I_{Ca} at -80mV. I_{Ca} influx correlated with glucagon exocytosis as either train of depolarization or UV photo-release of intracellular-loaded caged-Ca^{2+} stimulated C_m increase. 4 weeks after STZ treatment, GYY mice developed T1D, exhibiting higher fasting glucose, slower glucose clearance after a glucose challenge and higher fasting (control; 89 pg/ml vs. STZ group;122 pg/ml) and fed (control; 78 pg/ml vs. STZ group;112 pg/ml) serum glucagon levels. α cells in slices from these diabetic mice revealed augmentation of I_{Na} (control; 368 ± 43 pA vs. STZ group; 480 ± 71pA) and LVA I_{Ca} amplitudes (control; 40 ± 5 vs. STZ group; 49 ± 6 pA). HVA I_{Ca} however remained unaltered by T1D (control; 44 ± 5 pA vs. STZ group; 46 ± 6 pA) . Voltage-gated K^+ current was found to be increased (STZ group; 2.13 nA vs. control; 1.76 nA). α cell size was unchanged compared to control (control; 4.7 ± 0.20 pF vs. STZ group; 4.8 ± 0.23 pF).
Conclusion: GYY mouse α cell ion channel properties examined in slices were largely consistent with our previous findings and others, validating the feasibility of using pancreas slice approach to investigate α cells in normal and diabetic subjects. We postulate that the observed upregulation of I_{Na} and LVA I_{Ca} in diabetic α cells potentially elevates membrane potential that would more readily to trigger HVA Ca^{2+} channels opening, with ensuing initiation of action potential firing leading to glucagon secretion. This explains in part the observed glucagon hypersecretion in early stage of T1D.

Active CFTR channels are important for insulin- and glucagon secretion
A. Edlund[1], M. Hühn[2], M. Flodström-Tullberg[2], L. Eliasson[1];
[1]Clinical Sciencies Malmö, CRC, Lund University Diabetes Centre, Malmö, [2]Karolinska Institute, Huddinge, Center for Infectious Medicine, Stockholm, Sweden.

Background and aims: Cystic fibrosis (CF) is a monogenic autosomal recessive disease caused by mutation in the cystic fibrosis gene that encodes the chloride channel cystic fibrosis transmembrane conductance regulator (CFTR). One of the leading complications of CF is cystic fibrosis related diabetes (CFRD). The mechanism behind CFRD is unclear but the progressive inflammation in the exocrine pancreas has been suggested. Another possible mechanism is that CFTR is present in the islet cells and a mutation in CFTR interferes with hormonal secretion. The aim of this study was to investigate the presence of active CFTR channels in pancreatic alpha- and beta cells and if CFTR influence secretion and exocytosis.
Materials and methods: Patch-clamp recordings and capacitance measurements were performed on single mouse beta-cells. Detection of CFTR in islet cells was investigated using rt-PCR and confocal immunocytochemistry. Insulin-and glucagon secretion was measured using radio immunoassay (RIA).
Results: Mouse islets express CFTR mRNA as confirmed by rt-PCR (*n*=5) and CFTR protein was specifically detected in alpha- and beta cells using immunocytochemistry. Electrophysiological investigation of CFTR was performed using the standard whole-cell configuration and CFTR was activated by addition of forskolin (10 μM). In single mouse beta-cells, a cAMP-activated membrane conductance of 0.05 ± 0.03 nS/pF at negative potentials and 1.03 ± 0.18 nS/pF at positive potentials (*n*=12; P<0.001 *vs* in absence of forskolin) was measured. The conductance was significantly reduced (*n*=7; P<0.001) and the current almost totally inhibited in the presence of the CFTR-antagonist, CFTRinh-172 (10 μM). A similar CFTR current could be activated in pancreatic alpha-cells (*n*=5; P<0,017). In addition, cAMP-amplified glucagon secretion measured at 1 mM glucose was reduced by ~60% (*n*=8; P<0.001) in the presence of CFTRinh-172 (40 μM) and by ~40% (*n*=8; P<0.08) in the presence of another CFTR-antagonist, GlyH-101 (50 μM). Cyclic AMP- amplified insulin secretion at 16.7 mM glucose was reduced by ~30% in the presence of CFTRinh-172 (*n*=10; P<0.05) and by ~30% in the presence of GlyH-101 (*n*=11; P<0.05). Moreover, exocytosis elicited by a train of 10 membrane depolarisations and measured as an increase in membrane capacitance on single beta-cells was significantly reduced by 70 ± 10% (*n*=9; P<0.05) in the presence of cAMP (100 μM) and CFTRinh-172 (10 μM).
Conclusion: Our data indicate the presence of active CFTR in pancreatic alpha- and beta cells and the importance of this channel for glucagon- and insulin secretion. Further, CFTR inhibition reduced exocytosis in pancreatic cells. Thus, we suggest a role for CFTR in the control of the exocytotic process important for release of glucagon and insulin.

Distinct roles of voltage-gated potassium channels Kv2.1 and Kv2.2 in governing the secretion islet hormones

X. Li[1], J. Herrington[1], K. Ratliff[1], L. Ge[1], Y. Feng[1], A. Petrov[1], G. Eiermann[1], Y. Xiong[1], M. Jensen[2], H.E. Hohmeier[2], C.B. Newgard[2], N.A. Thornberry[1], A.D. Howard[1], B.B. Zhang[1], Y.-P. Zhou[1];
[1]Metabolic Disorders, Merck Research Laboratories, Rahway, [2]Biochemistry, Duke University, Durham, USA.

Background and aims: Voltage-gated potassium channel Kv2.1 has been suggested to regulate glucose stimulated insulin secretion (GSIS) in islets, yet little is known about the role of Kv2.2, the other member of the delayed rectifier K channel also expressed in islets.
Materials and methods: We studied the roles played by each of the two Kv channels individually in islets using siRNA mediated gene-silence, Kv2.1 knockout (Kv2.1-/-) mice and highly selective peptide and small molecule Kv2 blockers newly discovery in our laboratories.
Results: siRNA directed against Kv2.1 in INS-1 cells remarkably reduced the Kv current and augmented GDIS, whereas Kv2.2 siRNA had no effect on GDIS. Pancreatic β-cells from Kv2.1 knockout mice manifested significantly smaller Kv current and greater GDIS *in vitro*. GxTx-1E diminished Kv current completely and enhanced GDIS dramatically in isolated mouse islets. But surprisingly, GxTX-1E only had a minimal *in vivo* effect to lower blood glucose levels during IPGTT (intraperitoneal glucose tolerance test) in mice. We thus examined the effects of GxTx-1E and Kv2i-A, a small molecule blocker of Kv2.1 and Kv2.2 discovered in our laboratories, on the release of glucagon and somatostatin, the other two major islet hormones. Besides promoting insulin secretion, both GxTX-1E and Kv2i-A enhanced somatostatin (SST) release from the cultured islets or *in vivo* animals. The effect of GxTX-1E to promote SST secretion was still seen in islets from Kv2.1 knockout mice, and was further augmented when Kv2.2 expression was 65% ablated by adenoviral delivered siRNA, indicating that Kv2.2 but not Kv2.1 regulates SST secretion in the pancreatic islets. This was corroborated by high expression of Kv2.2 in SST secreting δ-cells of the islets revealed by *in situ* hybridization and immunohistochemistry.
Conclusion: Kv2.1 and Kv2.2 have distinct roles in regulating islet insulin and SST secretion. Development of selective Kv2.1 inhibitor and Kv2.2 activator may provide new avenue for novel insulin secretagogues for diabetes therapy.

Evidence of functional hemi-channels in beta cells: their opening by K^+-depolarisation and/or Ca^{2+}-omission

J. Tamarit-Rodriguez[1], J. Pizarro-Delgado[1], R. Martín-del-Río[2];
[1]Biochemistry, Complutense University, [2]Research Department, Hospital Ramón y Cajal, Madrid, Spain.

Background and aims: We have previously reported that islet depolarization (70 mM KCl + 0.25 mM diazoxide) induces release of GABA and taurine (Tau) and suppresses KIC-induced insulin secretion. The aim of this work is to characterize the responsible mechanism of this increased amino acid release.
Materials and methods: Insulin secretion of rat perifused islets was monitored by RIA. Islet content and release of amino acids were measured by fluorescent detection after pre-column derivatization with o-phtalaldialdehyde and their HPLC separation. Islet ATP and ADP contents were measured with the luciferin/luciferase system.
Results: At 5 mM glucose, Ca^{2+}-omission (0 mM Ca^{2+} + 0.1 mM EGTA) stimulated islet release of GABA (438.5 ± 35.4, n=4 vs.289.7 ± 41.2 pmol/30 islets x 60 min, n=4; p<0.03) and Tau (119.3 ± 11.5, n=4 vs. 66.7 ± 4.2 pmol/30 islets x 60 min, n=4; p<0.005) and suppressed proportionately their contents. 70 mM KCl depolarization potentiated the releasing effect of Ca^{2+}-omission on both GABA (747.1 ± 98.7, n=4 vs. 438.5 ± 35.4 pmol/30 islets x 60 min, n=4; p<0.03) and Tau (194.1 ± 28.1, n=4 vs. 119.3 ± 11.5, n=4 pmol/30 islets x 60 min, n=4; p<0.05) and diminished proportionately their contents. Islet ATP release could not be measured due to the presence of a very efficient ecto-nucleotidase activity resistant to available inhibitors. However, at 3 mM glucose, ATP content was decreased by the combination of depolarization and Ca^{2+}-omission (1.3 ± 0.14, n=12 vs. 2.8 ± 0.14 pmol/ islet, n=18; p<0.0001) without affecting the ATP/ADP ratio (p=0.05). At physiological $[Ca^{2+}]_o$, islet depolarization alone suppressed ATP content at 3 mM glucose (0.9 ± 0.1, n=6 vs. 2.9 ± 0.3 pmol/islet, n=6; p<0.0001) and slightly decreased the ATP/ADP ratio (0.95 ± 0.05, n=5 vs. 1.26 ± 0.08 pmol/ islet, n=5; p<0.011). 20 mM glucose prevented the loss of islet ATP induced by the combination of depolarization and Ca^{2+}-omission observed at 3 mM glucose (4.4 ± 0.16, n=8 vs. 4.6 ± 0.09 pmol/islet, n= 12; N.S.) and preserved the elevated ATP/ADP ratio (1.8 ± 0.17, n=7 vs. 2.2 ± 0.22 pmol/islet, n=12; N.S.). Mefloquine (50 uM) did not modify islet ATP content at 3 mM glucose but counteracted the combined effects of islet depolarization + Ca^{2+}-omission (2.1 ± 0.27, n=8 vs. 1.3 ± 0.14, n=12 pmol/islet; p<0.006); it also partially suppressed islet amino acid release under the same experimental conditions. 20 mM glucose stimulation of insulin secretion in perifused islets (100 ± 9.3%) was dose-dependently decreased by mefloquine to 84.8 ± 11.5% (10 uM; N.S.), 53.7 ± 7.3 % (25 uM; p<0.01) and 27.5 ± 5.2 % (50 uM; p<0.001). At concentrations above 100 uM, it stimulated a secretory response that was independent of the glucose and calcium concentration and it decreased islet insulin content.
Conclusion: Islet amino acids and ATP are released by procedures known to open hemi-channels/pannexins in other tissues. This is supported by the protective effect of mefloquine, a known connexin 36 inhibitor. Inhibition of insulin secretion by mefloquine highlights the importance of beta cell communication for an optimal insulin response to glucose.

Analysis of submembrane insulin granule behaviour by TIRF microscopy during moderate and strong K^+ depolarization

K. Hatlapatka[1], M. Matz[2], K. Baumann[2], I. Rustenbeck[1];
[1]Institute of Pharmacology and Toxicology, [2]Institute of Medicinal Chemistry, University of Braunschweig, Germany.

Background and aims: The release of a pool of membrane-adjacent secretory granules which are in a primed and docked state and await one final trigger, a depolarization-induced influx of Ca^{2+}, is held responsible for the first phase of glucose-induced insulin secretion. Recently, we observed that 15 mM K^+ led to a 20 mV depolarization and to a lasting increase of the cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$), but only to a modest transient increase in secretion, suggesting that the effect of depolarization on insulin secretion is only incompletely understood.
Materials and methods: Insulin secretion was measured by perifusion of mouse islets and MIN6 pseudoislets and ELISA of the fractionated effluate. The $[Ca^{2+}]_i$ of islets and MIN6 cells was measured with the Fura technique. Submembrane granules were visualized by transient transfection of MIN6 cells with an insulin-EGFP fusion protein and imaging by TIRF microscopy at 37°C. The images were evaluated by a purpose-made program written in MatLab to achieve a complete observer-independent quantitation.
Results: Islets perifused with 5 mM glucose showed only a transient increase in secretion when K^+ was raised to 15 mM. A subsequent elevation to 40 mM K^+ resulted in a prompt overshooting increase in secretion which remained increased as long as 40 mM K^+ was present. In contrast, $[Ca^{2+}]_i$ was continuously elevated by 15 mM K^+ and increased further when K^+ was raised to 40 mM. The same secretion and $[Ca^{2+}]_i$ pattern could be observed with MIN6 pseudoislets. MIN6 cells transfected with insulin-EGFP were therefore used to analyse the behavior of submembrane granules by TIRF microscopy at 5 time points: beginning, prior to high K^+, one each during 15 and 40 mM K^+ and one after washout of high K^+. At each time point a sequence of 100 images was acquired within 12 s. Referring to the first sequence as 100%, the numbers of submembrane granules at the next time points were 109%, 76%, 50% and 56%. More than 50% of the granules were long-term resident (≥ 12 s). The percentage of short-term resident granules (≤ 1 s) increased slightly during 15 mM K^+, then significantly during 40 mM K^+ and remained so after washout. This correlated with an increase of the percentage of newly arriving granules from 4% initially to 7% during 15 mM K^+ and to 15% during 40 mM K^+ and washout. Very similar percentages applied for departing granules (i.e. return or release). There were no such changes in control experiments. The total and the net distances covered by the submembrane granules were not affected by high K^+.
Conclusion: 40 mM K^+ affects arrival, departure and residence time of insulin granules, but not movement parallel to the membrane. 15 mM K^+ is moderately effective, which concurs with dynamic secretion measurements. Currently there is no indication that long-term resident granules are preferentially departing during stimulation.

Abnormal regulation of pancreatic beta cell Na,K-ATPase on glucose intolerant rats

A.R. Costa[1,2], C.M. Antunes[1,3], J. Cruz-Morais[1,2];
[1]Chemistry, University of Évora, [2]ICAAM - Institute of Mediterranean Agricultural and Environmental Sciences, Évora, [3]CNC - Centre for Neurosciences and Cell Biology, Coimbra, Portugal.

Background and aims: Glucose (G) is the most important physiological insulin secretagogue. It is widely accepted that, in pancreatic -cell, G evoked early ionic events such as membrane depolarization and Ca^{2+} influx through voltage dependent Ca^{2+} channels triggers insulin exocytosis. However, the role of other electrogenic systems, namely ionic pumps, to these events remains essentially uninvestigated. It is known that the activity of Na,K-ATPase is modified in type 2 diabetes (T2D). The pump is responsible for maintaining Na^+ and K^+ gradients across the plasma membrane and generates a net outward current as a result of $3Na^+/2K^+$ exchange. It remains elusive whether Na,K-ATPase activity is regulated by G in pancreatic β-cell and/or this current contributes to the ionic events regulating insulin secretion. The aim of this work was to assess G evoked regulation of Na,K-ATPase activity in intact -cells of normal and G intolerant rats.
Materials and methods: Pancreatic -cells, from normal (controls) or glucose-intolerant Wistar rats (GIR), were isolated and cultured (48h). Cell batches were pre-incubated (30min) with 2.1mM G to reach basal. Afterwards cells were challenged with [G] in the interval 0-11.1mM for 60min, for dose-dependence evaluation, or with 8.4mM G for 5-120min, for time-dependence evaluation. ATPase activity was assessed in intact cells by colorimetric quantification of Pi formed in 30min. Na,K-ATPase activity was calculated by the difference between the activities obtained in the absence and in presence the of 1mM ouabain.
Results: G evoked both time- and dose-dependent regulation of Na,K-ATPase. In β-cells from controls, G induced a bimodal regulation of Na,K-ATPase. In the absence of G, Na,K-ATPase activity was 0.056±0.015U/mg. Raising [G] to 2.1mM induced a ≈3 fold increase of Na,K-ATPase activity whereas a further increase in [G] in the interval of 5.6-11.1mM evoked a significant reduction of Na,K-ATPase activity to the levels observed in the absence of the secretagogue. Compared to 2mM G, the activity was reduced in 68%, 55% and 66% when [G] was increased to 5.6, 8.4 and 11.1mM, respectively (n=3-12). GIR β-cells exhibit an altered profile of response to the secretagogue; In the absence of G, Na,K-ATPase activity was ≈4 fold the activity observed in the controls (0.202±0.036U/mg; n=3). The pump activity remained unchanged for 2.1-5.6mM G and similar to maximal activity observed in the controls (0.188±0.035 U/mg, for 2.1mM G; n=4). A significant reduction of the pump activity in GIR β-cells was induced by 8.4mM G (0.118±0.018 U/mg). G (8mM) induced a time-dependent inhibition of Na,K-ATPase with a biphasic profile. Pump activity decreased to a minimum value (32%) after 20min exposure to G, showing a partial recovery to 45%, 46% and 47% for 30, 60 and 120min, respectively (n=5-12). GIR β-cells showed an attenuated response to G (59% activity after 20min) without any recovery (n=5-11).
Conclusion: This work demonstrates that Na,K-ATPase is finely regulated by G in pancreatic β-cell from normal subjects. This regulation is impaired in GIR where desensitization and an attenuation of the inhibitory action of G were observed. In summary, Na,K-ATPase contribution to G-induced ionic events and insulin secretion might be relevant in T2D development.

Interplay between [Ca2+]c and [Ca2+]ER in mouse beta cells: role of SERCA2b and SERCA3

M.A. Ravier[1,2], D. Daro[1], R. Cheng-Xue[1], P. Gilon[1];
[1]Endocrinology and Metabolism, University of Louvain, Brussels, Belgium, [2]Institut de Genomique Fonctionnelle, Inserm U661, Montpellier, France.

Background and aims: Pancreatic β-cells express 2 types of sarco-endoplasmic Ca^{2+}-ATPases, SERCA2b and SERCA3, which take up Ca^{2+} from the cytosol to the endoplasmic reticulum (ER). Whereas the changes in the cytosolic Ca^{2+} concentration ($[Ca^{2+}]_c$) have been well characterized in β-cells, the changes in the ER Ca^{2+} concentration ($[Ca^{2+}]_{ER}$) are still largely unknown. Here, we studied the correlation between $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$ and the roles of SERCA2b and SERCA3 in $[Ca^{2+}]_{ER}$ homeostasis.
Materials and methods: We generated an adenovirus encoding the Ca^{2+} indicator D4 and addressed it to the endoplasmic reticulum (D4ER). D4ER was expressed under the control of the rat insulin promoter in clusters of β-cells from C57BL6 (WT) mice or SERCA3KO mice. In most experiments, $[Ca^{2+}]_{ER}$ (D4ER) and $[Ca^{2+}]_c$ (Fura PE3) were simultaneously recorded.
Results: Confocal microscopy and immunocytochemistry demonstrated that D4ER was specifically expressed in the ER of β-cells. We ascertained our ability to study the correlation between $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$. This was the case since 45mM KCl increased both $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$, whereas acetylcholine elicited the expected anti-parallel changes of both parameters in β-cells from WT mice. During spontaneous $[Ca^{2+}]_c$ oscillations induced by 15mM glucose (G), $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$ oscillated in phase. G-induced $[Ca^{2+}]_c$ oscillations were larger and much steeper, whereas $[Ca^{2+}]_{ER}$ oscillations were smaller in SERCA3KO than in WT mice, suggesting that G-induced $[Ca^{2+}]_{ER}$ oscillations partly involve SERCA3. We then evaluated the relative contribution of SERCA2b or SERCA3 to the refilling of the ER in Ca^{2+} elicited by an acceleration of cell metabolism. In the continuous presence of diazoxide, i.e. when $[Ca^{2+}]_c$ remained low, G dose-dependently increased $[Ca^{2+}]_{ER}$ (half-maximal and maximal effects at 5 and 8 mM, respectively) and to a similar extent in β-cells from WT and SERCA3KO mice, demonstrating that SERCA2b is the only isoform responsible for this replenishment. To evaluate the contribution of both SERCA isoforms to the refilling of the ER in Ca^{2+} triggered by a rise in $[Ca^{2+}]_c$, β-cells were submitted to depolarizations with various [KCl] (10, 15, 25, 35, 45mM). As expected the rise in $[Ca^{2+}]_{ER}$ increased dose-dependently with the depolarizations. In WT β-cells, the changes in $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$ were parallel soon after the depolarization. Intriguingly, when $[Ca^{2+}]_c$ was kept high for a prolonged period (> 2 min with [KCl] ≥ 25mM), $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$ changes were antiparallel demonstrating that the ER started to release Ca^{2+} by a process that is referred to as atypical Ca^{2+}-induced Ca^{2+} release (CICR). The rises in KCl-elicited $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$ were, respectively, larger and smaller in SERCA3KO than in WT β-cells demonstrating that SERCA3 contributes to the refilling of the ER in Ca^{2+} when $[Ca^{2+}]_c$ increases. No atypical CICR was observed in β-cells from SERCA3KO mice.
Conclusion: $[Ca^{2+}]_c$ and $[Ca^{2+}]_{ER}$ oscillate in phase during spontaneous $[Ca^{2+}]_c$ oscillations induced by G. SERCA2b is the only isoform responsible for the Ca^{2+} replenishment of the ER elicited by an acceleration of cell metabolism whereas SERCA3 also contributes to the Ca^{2+} refilling of the ER when $[Ca^{2+}]_c$ increases. During prolonged and prominent $[Ca^{2+}]_c$ elevation, the ER releases Ca^{2+} possibly to avoid its overfilling by SERCA3.

563

Spatial control of Epac2 by cAMP and Ca^{2+}

O. Idevall Hagren, A. Tengholm;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Glucose-stimulated insulin release from β-cells is pulsatile and controlled by synchronized oscillations of the Ca^{2+} and cAMP concentrations beneath the plasma membrane ($[Ca^{2+}]_{pm}$ and $[cAMP]_{pm}$). Important effects of cAMP are mediated by the guanine nucleotide exchange factor Epac2, which promotes insulin secretion through activation of the small GTPase Rap1, as well as via interactions with the K_{ATP}-channel and components of the exocytosis machinery. Epac2 undergoes a conformational change upon cAMP binding allowing interaction with downstream effectors, but little is known about the subcellular localization of Epac2. The aim of the present study was to investigate the spatial control of Epac2 in β-cells by cAMP and Ca^{2+} signals.

Materials and methods: Evanescent wave fluorescence imaging was used to record plasma membrane association of fluorescence-tagged Epac2 in single MIN6 β-cells. $[cAMP]_{pm}$ and $[Ca^{2+}]_{pm}$ was measured in parallel using a fluorescent cAMP translocation biosensor and the Ca^{2+} indicator Fura Red, respectively.
Results: Rise of intracellular cAMP or direct activation of Epac by the selective agonist 007-AM caused rapid translocation of GFP- Epac2 from the cytoplasm to the plasma membrane. Increase of the glucose concentration from 3 to 11 mM triggered oscillatory translocation of GFP-Epac2 that were preceded by elevations of $[cAMP]_{pm}$ and $[Ca^{2+}]_{pm}$. The translocation was suppressed by 43±20% (n=16, P<0.01) and 41±8% (n=23, P<0.01) after inhibition of adenylyl cyclases or removal of extracellular Ca^{2+}, respectively. Rise of $[Ca^{2+}]_{pm}$ evoked by KCl-depolarization caused GFP-Epac2 translocation, but this effect was suppressed by inhibition of adenylyl cyclases. Ca^{2+} nevertheless contributed to cAMP-induced GFP-Epac2 translocation, since the response was reduced by 48±7% (n=43, P<0.01) after removal of extracellular Ca^{2+} and depletion of intracellular Ca^{2+} stores. However, the effect of Ca^{2+} was dual, and high $[Ca^{2+}]_{pm}$ spikes evoked by tetraethylammonium caused temporary dissociation of GFP-Epac2 from the membrane (40±7% reduction, n=32, P<0.01). Epac2 mutants lacking the cAMP-binding or Ras-association domains were unable to translocate and localized constitutively to the plasma membrane and cytoplasm, respectively.
Conclusion: Epac2 localization is dynamically controlled by both cAMP and Ca^{2+} signals. Epac2 recruitment to the plasma membrane should be important for the activation of effectors involved in the regulation of insulin secretion.

564

Crosstalk between cAMP- and Zn^{2+}-signalling in insulin secretion
O. Dyachok, O. Idevall, A. Tengholm, E. Gylfe;
Department of Medical Cell Biology, Uppsala University, weden.

Background and aims: Glucose stimulation of β-cells evokes synchronized oscillations of the sub-membrane cytoplasmic Ca^{2+} ($[Ca^{2+}]_{pm}$) and cAMP ($[cAMP]_{pm}$) concentrations, which underlie pulsatile insulin secretion (IS). Whereas Ca^{2+} is the principal trigger, cAMP is an important amplifier of IS. Zn^{2+} is present in high concentrations in insulin secretory vesicles and Zn^{2+} co-released with insulin has been proposed to exert a negative feedback on IS by inhibiting Ca^{2+} influx after activation of hyperpolarizing K^+ channels. cAMP turnover is also modulated by Zn^{2+}. In the present study, we investigated how glucose affects the sub-membrane Zn^{2+} concentration ($[Zn^{2+}]_{pm}$) and it's influence on $[Ca^{2+}]_{pm}$, $[cAMP]_{pm}$ and insulin secretion kinetics in single β-cells.
Materials and methods: Simultaneous measurements of $[Ca^{2+}]_{pm}$ and $[Zn^{2+}]_{pm}$ were performed in single MIN6 β-cells co-loaded with the fluorescent indicators Fura Red and FluoZin-3. $[cAMP]_{pm}$ was detected by a fluorescent protein-based translocation biosensor. Another translocation biosensor reported phosphatidylinositol-3,4,5-trisphosphate formation in the plasma membrane ($[PIP_3]_{pm}$) after autocrine insulin receptor activation, and this assay was used as readout for IS from single cells. Changes in $[Zn^{2+}]_{pm}$, $[Ca^{2+}]_{pm}$, $[cAMP]_{pm}$ and $[PIP_3]_{pm}$ were recorded with evanescent wave microscopy.
Results: Glucose stimulation of MIN6 cells induced pronounced $[Ca^{2+}]_{pm}$ and $[cAMP]_{pm}$ oscillations resulting in pulsatile is detected as $[PIP_3]_{pm}$ oscillations. Glucose also elevated $[Zn^{2+}]_{pm}$ and some cells showed synchronized oscillations of $[Zn^{2+}]_{pm}$ and $[Ca^{2+}]_{pm}$, which were particularly prominent after addition of the K^+ channel blocker tetraethylammonium. Blocking of voltage-dependent Ca^{2+} channels with methoxyverapamil or inhibition of Ca^{2+} influx by hyperpolarization with diazoxide prevented both $[Ca^{2+}]_{pm}$ and $[Zn^{2+}]_{pm}$ oscillations. Addition of exogenous Zn^{2+} to glucose-stimulated MIN6 cells resulted in amplification of the $[Zn^{2+}]_{pm}$ oscillations but marked inhibition of the $[cAMP]_{pm}$ and $[PIP_3]_{pm}$ responses as well as suppressed insulin release detected by ELISA. The Zn^{2+}-inhibited $[PIP_3]_{pm}$ oscillations were rescued by 8-Br-cAMP. In the absence of added Zn^{2+} the membrane permeable Zn^{2+} chelator TPEN abolished the Zn^{2+} signal and much amplified the $[Ca^{2+}]_{pm}$, $[cAMP]_{pm}$ and $[PIP_3]_{pm}$ responses to glucose stimulation.
Conclusion: These data reinforce the idea that Zn^{2+} feedback-regulates pulsatile insulin secretion by inhibiting cAMP signaling in β-cells.

Adenylate cyclase 8 is required for glucose-induced calcium signalling in pancreatic beta cells
M. Raoux[1], P. Vacher[2], J. Papin[1], B. Roger[1], C. Magnan[3], J. Lang[1];
[1]UMR CNRS 5248, Institut Européen de Chimie et Biologie, Université de Bordeaux, Pessac, [2]Inserm U916, Institut Bergonié, Université de Bordeaux, [3]CNRS EAC 4413, Université Denis Diderot, Paris, France.

Background and aims: Glucose raises $[Ca^{2+}]_i$ in β-cells, which is a pivotal action of the sugar. Its metabolism leads to an increase in ATP/ADP ratios and the ensuing closure of K_{ATP} channels results in membrane depolarisation and Ca^{2+} influx. Glucose also stimulates cAMP generation, a second messenger considered as an amplifier of the cellular effects of Ca^{2+}. We had previously observed that the Ca^{2+}-activated adenylate cyclase 8 (ADCY8) mediates incretin effect on $[Ca^{2+}]_i$ and that glucotoxicity strongly down-regulates ADCY8 in rat and human islets. In the present study, we addressed the role of cAMP and more specifically of ADCY8 in glucose-induced changes in $[Ca^{2+}]_i$.
Materials and methods: $[Ca^{2+}]_i$ was measured using INDO-1 in clonal INS-1E and primary mouse β-cells. In addition we used, for the first time, a novel electrophysiological approach in β-cells that is the extracellular recording of electrical signals with microelectrode arrays.
Results: In INS-1E cells, glucose-induced increases in $[Ca^{2+}]_i$ were significantly reduced from 330±43 (n=16) to 14±3 nM (n=20; 2p<0.001) by SQ22,536 (100 μM), a general inhibitor of adenylate cyclases. Similarly, the cAMP antagonist Rp-cAMPS (50 μM) reduced glucose effects to 47±12 nM (n=16; 2p<0.001) in INS-1E and from 258±64 to 34±9 nM in primary β-cells (n=21-25; 2p<0.005). In contrast, responses evoked by depolarization with KCl remained unchanged pointing towards a glucose-specific mechanism. The activation of kinases by cAMP, and particularly PKA, seems to be involved as H-89 (40 μM) reduced glucose-evoked $[Ca^{2+}]_i$-increases to 5±2 nM in INS-1E cells (n=11; 2p<0.001). In the same vein, glucose-evoked firing rates recorded with microelectrode arrays were decreased by H-89 in a reversible manner from 1.36±0.18 to 0.10±0.02 Hz in INS-1E (n=33; p<0.001) and from 1.91±0.50 to 0.22±0.15 Hz in mouse β-cells (n=7; p<0.01). Among adenylate cyclases, ADCY8 appeared to play a key role as its overexpression increased the amplitude of glucose-induced increase in $[Ca^{2+}]_i$ from 218±27 to 1005±115 nM and its knockdown reduced the response to 72±10 nM in INS-1E cells (n=7-51; 2p<0.001). In contrast, responses to KCl or thapsigargin remained unaltered. Similarly, knockdown reduced glucose-induced $[Ca^{2+}]_i$ increases in islet cells from 209±36 to 32±5 nM (n=21 each; 2p<0.001) without altering responses to KCl. Finally, preliminary data using $ADCY8^{-/-}$ knockout mice suggest equally a defect in glucose-induced $[Ca^{2+}]_i$ responses and impaired glucose tolerance under normal diet.
Conclusion: Taken together, these results indicate a permissive rather than only amplifying role of cAMP and specifically of ADCY8 in the sequence of events leading from glucose exposure to increases in $[Ca^{2+}]_i$ in clonal and primary β-cells. In line with the down-regulation of this gene during glucotoxicity in rat and human islets, our data underline the pivotal importance of this enzyme in normal β-cell function and potentially in type 2 diabetes.

Glucose and muscarinic stimulation trigger distinct diacylglycerol signals in pancreatic beta cells
A. Wuttke, H. Emanuelsson, A. Tengholm;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Diacylglycerol (DAG) is generated in the plasma membrane via phospholipase cleavage of phosphoinositides in response to nutrients and receptor stimuli. Several DAG-activated proteins like protein kinase C, protein kinase D and Munc13 have been implicated in the regulation of insulin secretion. The aim of this study was to characterize the temporal pattern of plasma membrane DAG signaling in insulin-secreting cells exposed to different stimuli.
Materials and methods: A biosensor based on the two adjacent DAG-binding C1 domains of rat protein kinase Cγ tagged to green fluorescent protein (C1aC1b-GFP) was used to monitor DAG in individual MIN6 β-cells. The probe translocates to the plasma membrane upon DAG formation, which was monitored with confocal and evanescent wave microscopy. The cytoplasmic Ca^{2+} concentration in the immediate sub-plasma membrane space was recorded with evanescent wave microscopy in cells loaded with the fluorescent indicator Fura Red.

Results: Confocal imaging of MIN6 β-cells expressing C1aC1b-GFP showed diffuse cytoplasmic fluorescence and a slight accumulation of the probe in the nucleus under basal conditions. Addition of 1 μM of the functional DAG mimetic phorbol myristate acetate caused rapid redistribution of the fluorescence to the plasma membrane. This translocation was detected as a pronounced increase of fluorescence when imaging the plasma membrane with evanescent wave microscopy. Activation of muscarinic receptors with carbachol caused a dose-dependent and sustained, plasma membrane translocation of C1aC1b-GFP with threshold and maximal response at about 0.1 and 100 μM (130±7 % fluorescence increase), respectively, and the half maximal effect at 7±0.7 μM (n=50). Depolarization with 30 mM K^+ caused a rapid increase in the plasma membrane C1aC1b-GFP fluorescence followed by a decline and brief (3-13 s duration), irregular spikes, often originating from a slightly elevated level. This response required influx of Ca^{2+}, since Ca^{2+}-deficient medium containing 2 mM EGTA reversibly removed all spiking. Elevation of the glucose concentration from 3 to 11 mM induced complex changes of the plasma membrane C1aC1b-GFP fluorescence. The majority of cells (55.5%) showed brief irregular high-amplitude (60±12 % fluorescence increase, n=25) spiking like during K^+ depolarization. In 15.5% of the cells, glucose triggered slow (0.31±0.2 min^{-1}), low-amplitude (28±6 % fluorescence increase, n=7) oscillations without spikes, and in 29% of the cells the high-amplitude spikes were grouped into bursts with similar frequency as the slow oscillations. The glucose-induced DAG signaling was Ca^{2+}-dependent and simultaneous measurements revealed that the initial increase of C1aC1b-GFP fluorescence was always preceded by an increase of the sub-plasma membrane Ca^{2+} concentration.
Conclusion: The plasma membrane DAG concentration shows distinct and complex changes in insulin-secreting cells exposed to receptor, nutrient and depolarizing stimuli, probably reflecting different modes of phospholipase C activation. The DAG signaling patterns may differently affect downstream effector proteins involved in the regulation of insulin secretion.

PS 39 Incretins and beta cell mass in rodents

567

Preservation of pancreatic beta cell mass in high fat-fed STZ treated mice by the Dipeptidyl peptidase-4 inhibitors Saxagliptin and Sitagliptin
S.M. Poucher[1], J. Francis[2], S. Vickers[3], S. Cheetham[3], G. Birmingham[3], K. Dickinson[3], B. Zinker[4], A. Bellamine[5], M. Kirby[6];
[1]Cardiovascular Discovery Department, AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom, [2]ASTL, AstraZeneca Pharmaceuticals, Charnwood, United Kingdom, [3]RenaSci Consultancy, Nottingham, United Kingdom, [4]Diabetes Drug Discovery, Bristol-Myers Squibb, Princeton, USA, [5]CV / Metabolism US Medical Strategies, Bristol-Myers Squibb, Princeton, USA, [6]DIabetes Drug Discovery, Bristol-Myers Squibb, Princeton, USA.

Background and aims: Saxagliptin is a potent, selective DPP-4 inhibitor, specifically designed for extended inhibition of the DPP-4 enzyme. DPP-4 inactivates incretins that stimulate glucose-dependent insulin secretion. A proposed mechanism of action involves protecting incretins from DPP-4 degradation, thus improving β-cell preservation in conditions of β-cell stress. In this study we investigated the β-cell preservation effects of saxagliptin and sitagliptin at similar exposures in relation to their potencies as DPP-IV inhibitors.
Materials and methods: C57BL/6J mice (12 per group) were placed on a 60% fat diet for 4 weeks prior to 50mg/kg streptozotocin (STZ, ip, daily for 3 days). All animals were randomised based on bodyweight, glucose, insulin and HbA1c. They were dosed with Vehicle (V) Sitagliptin (Sita) or Saxagliptin (Saxa) (10mg/kg/day, po) throughout the study commencing either one week prior to STZ treatment or 1 day after STZ treatment. Glycaemic control was determined by oral glucose tolerance tests (OGTT) 3 weeks post-STZ treatment and by fasting blood glucose 36 days post STZ. Automated imaging and analysis systems were used to determine β-cell mass using terminal formalin-fixed, paraffin-embedded samples taken 36 days after induction of treatment.
Results: Plasma compound concentration measured 24 hours after the final dose gave calculated unbound concentrations 7.9 and 3.1 fold above the Ki value for Saxa and Sita, respectively. Glycaemic control and β-cell mass data are given in the table.

Glycaemic control and beta cell mass following compound treatment

	Vehicle STZ	Sita Pre STZ	Sita Post STZ	Saxa Pre STZ	Saxa Post STZ
FBG (mM)	17.9±1.3	16.1±0.7	15.6±1.2	17.6±1.2	14.4±1.0*
HbA1c (%)	6.8±0.2	6.2±0.2*	6.3±0.2	6.5±0.2	6.1±0.2†
OGTT Glucose $AUC_{Baseline}$ (mM.min)	32.9±1.9	28.4±1.0†	28.4±0.8†	28.3±1.3†	28.3±1.8†
OGTT Insulin $AUC_{Baseline}$ (ng/ml.min)	-0.05±0.14	0.12±0.09	0.09±0.20	-0.05±0.17	0.19±0.17
Beta cell mass (mg)	0.13±0.03	0.16±0.02	0.42±0.06†	0.23±0.03*	0.28±0.05*

(*Data are mean and sem calculated from the residuals of the SAS ROBUSTREG procedure and t-tests undertaken using two-sided tests. *, P<0.05 and †, P<0.01 compared to vehicle*).

In animals treated post STZ, both saxa and Sita significantly reduced glucose $AUC_{Baseline}$ with no effect on insulin $AUC_{Baseline}$ during OGTT. Saxa induced a significant reduction in HbA1c and fasting glucose levels. Both treatments demonstrated a significant improvement in β-cell mass. Mice dosed pre STZ showed that both Saxa and Sita again reduced the glucose $AUC_{Baseline}$. Saxa also demonstrated improvement in β-cell mass compared with vehicle.
Conclusion: Overall both Saxa and Sita showed similar improvements in glycaemic control and β-cell mass preservation in the high fat-fed, STZ mouse model of pancreatic β-cell degeneration. We have demonstrated for the first time that saxagliptin along with improving glycaemic control had a positive impact on β-cell preservation in a rodent model of type 2 diabetes.

Protective effects of DPP-4 inhibitor against increased beta cell apoptosis with multiorgan glucolipotoxicity by a combination of dietary sugar and fatty acid

J. Shirakawa[1], E. Takeda[2], Y. Terauchi[1];
[1]Endocrinology and Metabolism, Yokohama City University, [2]Clinical Nutrition, Tokushima University, Japan.

A composition of diet affects metabolic states in diabetes. We investigated diet-induced glucolipotoxicity and effects of des-fluoro-sitagliptin (DFS), a DPP-4 inhibitor, on it, in β cell-specific glucokinase haploinsufficient (*Gck*$^{+/-}$) diabetic mice. We challenged the mice with diet containing a combination of sucrose and oleic acid (SO), or sucrose and linoleic acid (SL) for 25 weeks. In *Gck*$^{+/-}$ mice, but not in the wild-type mice, SL induced impaired insulin secretion in response to glucose. Histochemical analyses revealed that, in *Gck*$^{+/-}$ mice fed SL, β cell mass and proportion of β cells to islet cells were significantly decreased, α cell were dispersed into islet, and both CHOP- and TUNEL-positive β cells were significantly increased, compared to those fed SO. Analysis of mRNA expression showed that CHOP, Bip and SREBP-1c were significantly increased and E-cadherin was significantly decreased in islets of *Gck*$^{+/-}$ mice fed SL, compared to SO. These results indicated that the SL diet induced endoplasmic reticulum (ER) stress and apoptosis in β cells, which resulted in β cell loss and abnormal islet morphology by modification of SREBP-1c and E-cadherin expression. Whereas histology and flow cytometry of epididymal fat indicated increased number of F4/80^{+} CD11c^{+} M1 macrophages and CD8^{+} T cell in SL, compared to SO. We next evaluated DFS monotherapy for increased beta cell apoptosis and glucolipotoxicity in *Gck*$^{+/-}$ mice fed SL diet with 1.1% DFS. Treatment with DFS improved glucose tolerance, protected against β cell apoptosis, restored β cell mass, and normalized islet morphology in *Gck*$^{+/-}$ mice fed SL. DFS normalized the changes of islet mRNA expression of CHOP, Bip, SREBP-1c and E-cadherin by SL diet. DFS also reduced CD8^{+} T cell and M1 macrophage infiltration to epididymal fat. Furthermore, DFS prevented liver steatosis in SL-fed mice. Liver mRNA expression of SREBP-1c and SCD-1 were decreased, and PPARα was increased in DFS treated group. Taken together, DFS protected against metabolic disorders in multiple organs induced by dietary sugar and fatty acid (multiorgan glucolipotoxicity).

Enhanced proliferation of islet beta cells in spontaneously diabetic GK rats treated with DPP-IV inhibitor (Vildagliptin)

S. Yagihashi, H. Mizukami, W. Inaba, K. Takahashi;
Pathology and Molecular Medicine, Hirosaki University, Japan.

Background and aims: Progressive decline of beta cell mass is a hallmark of either obese or lean type 2 diabetic patients. Currently, incretins are expected to not only exert insulin secretion but to protect beta cell depletion. It is not entirely clear, however, whether DPP-IV inhibitors have a potential to maintain beta cell survival or to prevent apoptotic processes of beta cells in lean type 2 diabetes. Spontaneously diabetic GK rats are non-obese, typical of lean type 2 diabetes model. In this study, we studied the effects of DPP-IV inhibitor on the islet pathology in GK rats to explore how it can protect the development of beta cell depletion.
Materials and methods: GK rats 4 weeks of age were orally given DPP-IV inhibitor (Vildagliptin 15mg/kg)(VG) twice a day for following 18 weeks. Untreated GK rats were given saline alone. Non-diabetic Wistar rats served controls. At end, all the animals were sacrificed after glucose tolerance test (GTT) (2g/kg) and insulin tolerance test (ITT) (0.5U/kg). Then, pancreases were subjected to evaluation of islet pathology and morphometric analysis of beta cells.
Results: VG treatment significantly suppressed postprandial hyperglycemia and food intake in GK rats, but did not affect blood glucose levels in normal Wistar rats. Gluose intolerance on GTT was also significantly improved in VG-treated GK rats. Lowered insulin secretion in GK rats after meals was significantly improved by VG treatment while no effects on Wistar rats. Insulin resistance detected in GK rats on ITT was significantly improved at 30 min point in VG-treated GK rats, while there was no effect in Wistar rats. The islets in GK rats were atrophic and irregular mixed with macrophage infiltration. VG-treated GK rats exhibited marked hyperplastic islets and less inflammatory changes. Islet morphometry disclosed significant decline of islet volume (48% of Wistar) and beta cell mass (41% of Wistar) in GK rats.VG-treated GK rats recovered the islet volume (120% of Wistar) and beta cell mass (103% of Wistar). Volume density of alpha cells was also decreased in GK rats and corrected by VG-treatment. Proliferation rate of beta cells as revealed by MIB-1 index was significantly reduced in GK rats (21% of Wistar) and VG-treated GK rats recovered the index (5.6 times of untreated GK rats). Apoptotic cells in the islets were not detected in any group, either diabetic or non-diabetic groups. .
Conclusion: Our present study demonstrated that significant recovery of islet size and beta cell volume density was obtained in lean type 2 diabetic GK rats when treated with VG. The effects were mainly caused by enhanced proliferation of beta cells and associated with improved glucose intolerance and insulin secretion.

GLP-1 counteracts fatty acid inducing expression of PANDER, an apoptotic cytokine secreted from pancreatic islets, through activating Akt pathway

X. Cao, S. Chen, H. Xiao, S. Chen, X. Mo, Y. Li;
Endocrinology, First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

Background and aims: PANDER is a novel discovered cytokine that is secreted from pancreatic islet cells. It has been demonstrated that overexpression of PANDER induces pancreatic beta-cell apoptosis and dysfunction. To a better understanding of the pathophysiological role of PANDER in the islet beta-cells, we analyzed the effects of fatty acid and the counteracting effects of GLP-1 on PANDER expression and the possible mechanism.
Materials and methods: Beta-TC3 cells were cultured with or without Palmitic acid (PA), and/or GLP-1, Akt inhibitor (Akti). Cell viability was measured with MTT. Annexin-V-FITC/PI FACS was used to analyze cell apoptosis. PANDER mRNA and protein expression were measured by real-time fluorescence quantitative PCR and western blot, respectively.
Results: PA decreases cell viability of pancreatic beta-TC3 cell in a dose dependent manner as measured with MTT, Cell viability reduced one third when cells were treated with 0.8mmol/L PA, and a further decrease of 40% was observed when 1.0 mmol/L PA was used. Cell viability were increased significantly in PA + GLP-1 treated cells comparing to the PA treated cells ($P<0.05$). There were no significant differences between control group and PA + GLP-1 group($P>0.05$). Annexin-V-FITC/PI FACS analysis has showed that the apoptotic rate of beta-TC3 cells were (18.20 ± 2.14)%, (52.73 ± 3.29)% , and (34.49 ± 1.57)% in control, cells treated with PA, and cells treated with PA + GLP-1, respectively. PA increased cell apoptosis significantly (vs control, $P <0. 05$), and GLP-1 rescued cells from PA inducing apoptosis. Comparing to the PA treated cells, the apoptotic cells was significantly lower in cells treated with PA + GLP-1 ($P <0. 05$). PANDER mRNA expression is presented by F value of real time-PCR. The lower of F value, the higher the mRNA expression level. The F values were (1.00 ± 0.00) %, (0.16 ± 0.16) %, and (2.01 ± 0.46) % in control cells, cells treated with PA, and cells treated with PA + GLP-1 respectively. PA increased PANDER mRNA expression significantly (vs control, $P <0. 05$), while GLP-1 decreased PA inducing PANDER mRNA expression (vs PA, $P <0. 05$). Western blot has shown that PA induced 1.5 fold increase of PANDER protein expression, and there is no significant difference of PANDER protein expression between the control and PA+GLP-1 treated cells. GLP-1 reduced PA inducing PANDER protein expression significant (vs PA, $P <0. 05$). The p-Akt protein expression was increased in both of the GLP-1 and GLP-1+PA groups. When Akti was added, there are no significant differences of PANDER protein expression between PA and PA+GLP-1 treated cells were observed. The effect of GLP-1 on PA inducing PANDER expression was reduced.
Conclusion: GLP-1 counteracts PA inducing PANDER expression and rescues beta-cells from PA inducing apoptosis. This effect of GLP-1 on PA inducing PANDER expression is partially through activating the Akt pathway.

Exendin-4 inhibits palmitate-induced apoptosis in pancreatic beta cells

A. Natalicchio[1], R. Labarbuta[1], M.R. Orlando[1], F. Tortosa[1], A. Leonardini[1], A. Cignarelli[1], M. Melchiorre[1], A. Peschechera[1], P. Marchetti[2], S. Perrini[1], L. Laviola[1], F. Giorgino[1];
[1]Endocrinology & Metabolic Diseases, D.E.T.O., University of Bari, [2]Endocrinology and Metabolism of Transplantation, AOU, University of Pisa, Italy.

Background and aims: Type 2 diabetes is characterized by a progressive decline in the number of insulin-producing beta-cells, largely due to increased cellular apoptosis. Free fatty acids (FFA) are essential energy metabolites in the normal state, but induce beta-cell dysfunction and death when their levels are chronically increased, thus contributing to the pathogenesis of type 2 diabetes. GLP-1 and its long-acting receptor agonist exendin-4 (ex-4) increase the survival of beta-cells exposed to various pro-apoptotic stimuli, including FFA. The aim of this study was to investigate the mechanisms of FFA-induced beta-cell apoptosis and the potential protective effects of GLP-1 mimetics on this response in the rat insulin-secreting cell line INS-1 and in isolated human islets.
Materials and methods: INS-1 beta-cells and isolated human islets were exposed to 0.5 mM palmitate for several h. The effects of ex-4 were evaluated by pre-incubating INS-1 cells with 10 nM ex-4 for 16 h. Protein content and phosphorylation of intracellular signaling intermediates were evaluated by immunoprecipitation and immunoblotting techniques. Gene expression was evaluated by qRT-PCR. Beta-cell apoptosis was quantified by an ELISA assay evaluating oligosome release into the cytosol.
Results: Exposure of both INS-1 cells and isolated human islets to 0.5 mM palmitate, a saturated fatty acid, up to 48 h induced a 2.5-fold increase in cell apoptosis, measured by evaluation of cytosolic oligosomes ($p<0.05$) and cleaved caspase-3 ($p<0.05$). Palmitate induced a 3.5-fold increase in the phosphorylation of JNK1/2, a class of mitogen-activated protein kinases largely involved in beta-cell apoptosis, evaluated by both immunoblotting and immunofluorescence ($p<0.05$), and a 3.8-fold increase in the mRNA levels of the JNK substrate c-jun ($p<0.05$), evaluated by qRT-PCR. Preincubation with 10 μM SP600125, a specific JNK inhibitor, for 2 h prevented palmitate-induced apoptosis ($p<0.05$ vs. palmitate-treated cells). Treatment with 10 nM ex-4 for 16 h inhibited both palmitate-induced activation of JNK1/2 ($p<0.05$ vs. palmitate-treated cells) and apoptosis ($p<0.05$ vs. palmitate-treated cells) in both rat insulin-secreting cells INS-1 and isolated human islets. Furthermore, ex-4 inhibited palmitate-induced phosphorylation of the upstream stress signaling kinases MKK4 and MKK7, which are implicated in JNK activation ($p<0.05$ vs. palmitate-treated cells), and increased the protein content of Islet-Brain 1 (IB1), a blocker of the stress-induced JNK pathway ($p<0.05$).
Conclusion: Palmitate induces apoptosis of human and rat beta-cells by activating JNK1/2, and the GLP-1 analog ex-4 prevents palmitate-mediated apoptosis, at least in part by interfering with the JNK activation pathway. These results provide evidence that the ability of ex-4 to prevent FFA-induced apoptosis involves inhibition of the JNK pathway, identifying an important mechanism by which GLP-1 receptor agonists may halt beta-cell death triggered by metabolic abnormalities.

PEGylated PYY_{3-36} has beneficial effects on glucose handling and exhibits islet sparing effects in db / db mice

A. Konkar[1], W. Danho[2], I. Mikaelian[3], R. Garrido[3], L. Rumennik[1], C. Spence[1], T. Truitt[4], H.A. Salari[1], G. Ehrlich[5], N. Brown[1], K. Conde-Knape[1], C. Rondinone[1], H.L. Char[6];
[1]Metabolism Discovery, [2]Discovery Chemistry, [3]Non clinical Safety, [4]Discovery Technologies, [5]Formulation Research, [6]Pharmaceutical & Analytical R&D, Hoffmann-La Roche Inc., Nutley, USA

Background and aims: NPY2-receptor peptide agonists suppress appetite in animal models of obesity, and therefore show great promise as treatment for obesity. However, their anti-diabetic potential has not been fully explored. In this study we investigated the anti-diabetic potential of long acting PEGylated PYY_{3-36} (PEG-PYY).
Materials and methods: Acute effect of PEG-PYY (3, 10, 20 and 30 mg/kg) on fasting glucose 26 h after a single subcutaneous (sc) administration was measured in diabetic 11-week old female *db/db* mice (Jackson Laboratories, Bar Harbor, ME). An oral glucose tolerance test was conducted to determine the effects on glucose disposal. We next examined the effects of PEG-PYY (sc, q2d) administration on glucose handling and islet morphology following sub-chronic dosing for 6 weeks in 9-week old *db/db* mice. The effects of 3-week PEG-PYY treatment (q2d) on body weight and insulin sensitivity were measured in male C57Bl/6 DIO mice (Jackson laboratories).
Results: PEG-PYY exhibited high NPY2-receptor selectivity (>100-fold) against related NPY-receptors. In leptin receptor deficient diabetic *db/db* mice, a single sc dose of PEG-PYY produced a 61% reduction in fasting blood glucose levels at 26 h post-dose. In addition, there was a significant improvement in glucose handling observed following an oral glucose challenge. Similar benefits were observed following sub-chronic dosing with PEG-PYY. In 9-week old *db/db* mice, PEG-PYY (20 mg/kg) injected every other day for 6-weeks improved glucose handling and had an islet sparing effect. A substantial improvement in islet morphology and insulin immunoreactivity was observed in PEG-PYY treated mice. In addition to its anti-diabetic benefits, PEG-PYY displayed robust anti-obesity effects as expected. Following sub-chronic dosing in DIO mice, a sustained reduction in body weight gain (12% @ 20 mg/kg) and an improvement in insulin sensitivity were observed. Significant improvements in levels of glucose, insulin, triglycerides and cholesterol were also noted.
Conclusion: In summary, we have observed that PEG-PYY improves glucose handling following an acute dose diabetic *db/db* mice. Sub-chronic treatment with PEG-PYY delayed the onset of diabetes in mildly hyperglycemic *db/db* mice and maintained islet health. These benefits of PEG-PYY likely involve its effects on insulin sensitivity, food intake, weight gain and lipid metabolism. Thus long acting PYY analogs have the potential to be developed as treatments for diabesity, with the added benefit of improved lipid parameters.

PS 40 Hypoglycaemia in type 2 diabetes

573

A basal–bolus regimen of insulin glargine and insulin glulisine results in a lower rate of hypoglycaemia relative to endpoint HbA_{1c} versus twice-daily premixed insulin in type 2 diabetes patients

A. Fritsche[1], M. Larbig[2], H.-U. Häring[1], The GINGER Study Group;
[1]Fourth Medical Department and Policlinic, University Tübingen, Germany, [2]sanofi-aventis, Berlin, Germany.

Background and aims: We recently demonstrated, in the GINGER study, that an intensified basal–bolus regimen using insulin glargine (GLAR) and insulin glulisine (GLU) provides significantly superior glycaemic control compared with premixed insulin therapy (ΔHbA_{1c} reduction 0.5%; Table) in a population with long-standing insulin-treated type 2 diabetes mellitus (T2DM). Although a difference in rates of hypoglycaemia favouring the basal–bolus arm was present, this was not statistically significant. It is well known that greater improvements in HbA_{1c} are associated with higher rates of hypoglycaemia. The aim of this analysis was to investigate the rate of hypoglycaemia relative to the achieved glycaemic control in terms of HbA_{1c}.
Materials and methods: In this 52-week, open, randomized, multinational, multicentre clinical trial, mealtime GLU and once-daily GLAR (n=153) was compared with an optimized conventional therapy of twice-daily premixed insulin (n=157) in T2DM patients inadequately controlled with their previous premixed insulins. In the premixed insulin group, 63 subjects received a combination of NPH/aspart. At baseline, the characteristics of the total study population (49% female) were (mean ± standard deviation): age, 61 ± 8 years; body mass index, 30.1 ± 3.7 kg/m^2; diabetes duration, 13 ± 6 years; and insulin use, 5 ± 4 years. We used negative binomial regression analysis to model hypoglycaemia outcomes by endpoint HbA_{1c}, adjusting for baseline HbA_{1c} and diabetes duration, taking zero inflation into account.
Results: The subjects with GLAR/GLU therapy had a 24.5% lower rate of overall hypoglycaemia (1399.17 ± 2324.24 vs 1854.31 ± 3694.83 events per patient year for GLAR/GLU and premix, respectively; unadjusted rate; Table) than the whole premix group (p=0.1211 from the adjusted model) and a 43.3% (p=0.0196) lower rate of overall hypoglycaemia than the NPH/aspart subgroup. When the analysis only included patients with at least one episode of hypoglycaemia during the study, the subjects with GLAR/GLU therapy had a 26.5% (p=0.0442) and 40.7% (p=0.0086) lower rate of overall hypoglycaemia than the whole premix group and NPH/aspart subgroup, respectively. Analyses with confirmed hypoglycaemia yielded similar results.
Conclusions: In the GINGER study, basal–bolus treatment with GLAR/GLU displayed a lower rate of hypoglycaemia in relation to endpoint HbA_{1c} compared with premixed insulin therapy. This was more pronounced in the analysis comparing the NPH/aspart-treated subgroup with basal–bolus treatment. Therefore, a basal–bolus regimen with insulin analogues is safer than premixed insulin therapy in T2DM patients with long-standing diabetes, when considering endpoint HbA_{1c}.

Table: Hypoglycaemia and HbA1c

	Insulin glargine/insulin glulisine	Premix	
		Al	NPH/aspart
Hypoglycaemia (events per 100 patient–years; safety population)			
	n=153	n=157	n=63

Detection of patient-specific intra-day patterns among hypoglycaemia episodes using continuous glucose monitoring

R. Cheng, T.C. Dunn;
Abbott Diabetes Care, Alameda, USA.

Background and aims: Incidence of hypoglycemia can be affected by insulin dosing, exercise, meals and sleep. Patterns in lifestyle and treatment decisions can result in consistent hypoglycemic patterns. Rapid computational screening of patient data can identify times of day with significant temporal patterns, which can then inform self-management adjustments that lead to improved glycemic control. A computational method for identifying patient-specific patterns in hypoglycemic episodes is proposed and applied to CGM data from a 40-day Freestyle Navigator® System home-use study to evaluate the impact of unmasked CGM readings on hypoglycemic patterns.
Materials and methods: 64 (T1DM=46, T2DM=18, all insulin users) subjects were selected for analysis based on high data availability and presence of at least 2 hours of hypoglycemia (<3.89 mmol/L) over the 40 day study. Subjects had glucose data masked for the first 20 days and unmasked for the following 20 days. During the masked phase, subjects were not able to see their CGM glucose values or trends and did not have glucose threshold or projected alarms available. CGM data from each subject's 20-day phases are divided into 2,880 ten-minute segments and categorized as hypoglycemic or not. For each subject, the number of ten-minute hypoglycemic segments is counted in each of six periods of the day (Early Morning: 4:00-8:00, Late Morning: 8:00-12:00, Early Afternoon: 12:00-16:00, Late Afternoon: 16:00-20:00, Early Night: 20:00- 0:00, Late Night: 0:00-4:00). Any period of the day with 30 or more hypoglycemic segments (corresponding to an average of 1.5 segments, or 15 minutes of hypoglycemia, in a given four hour period per day) is labeled as a persistent hypoglycemia pattern for that subject. The proportions of subjects with such patterns during the masked and unmasked phases were compared for each period of the day using pooled-proportion *z*-tests.
Results: The proportion of subjects with persistent hypoglycemia patterns differed significantly between the masked and unmasked phases in the Early Night (28%, 5%, p=0.0003) and Late Night (38%, 6%, p < 0.0001) periods. In the Early Morning (28%, 16%, p=0.0872), Late Morning (8%, 6%, p=0.7296), Early Afternoon (8%, 8%, p=1.0000) and Late Afternoon (17%, 6%, p=0.0544) periods, the proportion of subjects with persistent hypoglycemia patterns did not differ significantly.
Conclusion: The proposed computational method is useful for identifying periods of the day with hypoglycemic patterns on a per-subject basis. When used to compare masked and unmasked phases of a CGM home-use study, the incidence of persistent hypoglycemia was found to be significantly lower during the Early Night and Late Night periods of the unmasked phase relative to the masked phase. The method can be extended to identify other glycemic episodes of interest (such as hyperglycemia) over different time periods (e.g. days of the week). Prospective studies would be needed to evaluate the method's ability to improve therapy decisions.

Relationship of hypoglycaemia with medication, discontinuation and costs in type 2 diabetes mellitus patients

M. Bron[1], A.P. Yu[2], M. Marynchenko[2], H. Yang[2], O. Dabbous[1], S.X. Sun[1];
[1]Takeda Pharmaceuticals International, Inc., Deerfield, [2]Analysis Group, Inc., Boston, USA.

Background and aims: Hypoglycemia is a common and potentially severe adverse effect of antidiabetic treatment and poses significant barrier to main-

taining tight blood glucose control. (Amiel, 2008; Cryer, 2009) This study investigates the clinical and economic effect of hypoglycemia in type 2 diabetes mellitus (T2DM) patients initiated on oral and/or insulin antidiabetic drugs (OADs). Risks of hypoglycemia, likelihood of discontinuation, medical costs and medication type are compared between patients diagnosed with hypoglycemia vs. no hypoglycemia.
Materials and methods: T2DM patients initiated on OADs were identified in the Ingenix IMPACT Database (1999-2008). Included patients were ≥18 years old and had ≥1 year of continuous eligibility following the index date (first OAD prescription). Hypoglycemia risk factors in the subsequent 6-month interval were examined with multivariate Cox PH models adjusting for demographic characteristics and time-varying covariates (diabetes treatments and co-morbidities). The effect of hypoglycemia and other factors on antidiabetic treatment discontinuation was analyzed using GEE models with repeated measures. Annual cost outcomes for hypoglycemia were analyzed using GLM regressions.
Results: A total of 212,061 T2DM patients with ≥1 OAD treatment were identified, with 4,860 (2.3%) patients having a hypoglycemia diagnosis in the first year following the index date. Use of sulfonylureas (HR=1.58, p<.0001), insulins (HR=1.77, p<.0001), meglitinides or alpha-glucosidases (HR=1.27, p<.0001) was associated with a significant increase in hypoglycemia risk in the next 6-month interval. Use of DPP-4 inhibitors (HR=0.79, p=.0141), TZDs (HR=1.06, p=.0133) or metformin (HR=0.99, p=.8203) had minimal effect on hypoglycemia risk. Hypoglycemia diagnosis in a given 6-month interval significantly increased the likelihood of treatment discontinuation (OR=1.27, 95% CI=1.23, 1.32) within the same and the next 6-month interval (OR=1.14, 95% CI=1.09, 1.19). Moreover, for patients with a hypoglycemia diagnosis, average annual total costs (medical+drug costs, $18,273 vs. $8,908, p<.0001) and diabetes-related costs ($8,969 vs. $3,220, p<.0001) were significantly higher than for those without a diagnosis.
Conclusions: Patients experiencing hypoglycemia are at a higher risk of therapy discontinuation while hypoglycemia risk varies among treatments; insulin and SUs are associated with the most risk within the short term. The cost impact is twice as high with hypoglycemia compared to no hypoglycemia due to significantly higher total medical and diabetes-related costs.

Impact of HbA_{1c} and sulfonylurea use on hypoglycaemia in type 2 diabetes mellitus

K. Clements[1], M. Bron[2], D. Taylor[1], N. Emptage[1], S. Hudgens[2], O. Dabbous[2];
[1]i3 Innovus, Medford, [2]Takeda Pharmaceuticals International, Inc., Deerfield, USA.

Background and aims: This study examined the relationship between HbA1c level, oral antidiabetics, and hypoglycemia among type 2 diabetes mellitus (T2DM) patients receiving sulfonylureas (SU).
Materials and methods: A retrospective claims analysis of the I3 Innovus population from Jan 1, 2002-Dec 31, 2008 was conducted on T2DM patients with no history of diabetes-related complications or recent (3 months prior) T2DM medication changes (N=10,291). Patients receiving SU at baseline were included and classified as high or low dose based on the median SU dose (10 mg glyburide or glipizide, 4 mg glimepiride). Dose was classified as high dose if the average daily dose was above the median dose. In addition to SU, insulin use was also assessed. The outcome measure was incidence of diabetes-related hypoglycemic events, derived from claims with an ICD-9 code for hypoglycemia. Cox proportional hazards models measured the association between HbA1c and hypoglycemia, adjusting for clinical and demographic characteristics.
Results: At baseline for all 10,291 SU patients (mean age 57; 57% male; mean HbA1c 7.8%), 35% (n=3,628) of patients received high-dose SU; 7.7% (n=788) received SU and insulin. Over the average 3 year follow-up period, 7.2% (n=736) had a hypoglycemic event. The likelihood of a hypoglycemic event increased monotonically by HbA1c. Specifically, those with high baseline index HbA1c (≥9.0) were 47.2% more likely to have a hypoglycemic event in the follow-up period (OR 1.472, CI=1.094, 1.982). Similarly, patients receiving high-dose SU were 35.7% more likely to have hypoglycemic events than low-dose patients, and those patients on insulin in addition to SU had an increase in likelihood of 72.1% (Table 1).
Conclusion: The results indicate that high-dose SU and increased HbA1c are associated with increased likelihood of hypoglycemic events.

Risk factors for symptomatic hypoglycaemia in people with type 2 diabetes mellitus initiated on insulin therapy: evidence from the CREDIT study

G. Vespasiani[1], N. Freemantle[2], B.J. Balkau[3], N. Danchin[4], E. Genestin[5], M. Marre[6], M. Marre[6], R. Kawamori[7], P. Home[8];
[1]Diabetology and Metabolic Disorders Centre, San Benedetto Del Tronto, Italy, [2]Department of Primary Care and General Practice, University of Birmingham, Edgbaston, United Kingdom, [3]INSERM CESP U1018, Villejuif, France, [4]Division of Coronary Artery Disease and Intensive Cardiac Care, Paris, France, [5]sanofi-aventis, Paris, France, [6]Université Paris, France, [7]Department of Medicine, Juntendo University, Tokyo, Japan, [8]Institute of Cellular Medicine – Diabetes, Newcastle University, United Kingdom.

Background and aims: Hypoglycaemia has been suggested to be a potential causative factor in the development of diabetes-associated cardiovascular disease (CVD). We evaluated risk factors for symptomatic hypoglycaemia in the CREDIT study, a 314-centre, multinational, non-interventional, prospective study designed to investigate the effects of insulin initiation and long-term glycaemic control on CVD risk, with 3031 type 2 diabetes mellitus (T2DM) patients enrolled.
Materials and methods: Patients with at least one documented episode of symptomatic hypoglycaemia between 6 months and 1 year after initiating insulin were identified. Potential factors associated with hypoglycaemia (including patient demographics, medical history, CVD risk factors, glycaemic control and diabetes treatment) were described and assessed in a multivariable stepwise logistic regression. To enter and retain each factor in the model a p value of 0.20 and 0.05, respectively, was required. Multivariable analysis was adjusted for country.
Results: Of 2510 patients included in this analysis, 504 (20.1%) experienced at least one documented episode of symptomatic hypoglycaemia over the analysis period. In the final multivariable model, body mass index (BMI) at insulin initiation and HbA_{1c} level following 1 year of treatment were inversely correlated with symptomatic hypoglycaemia (Table). Each 1% increment in HbA_{1c} levels at 1 year was associated with a 25% reduction in the risk of symptomatic hypoglycaemia over the course of the study. Each 1 kg/m^2 increment in BMI at initiation was associated with a 3% reduction in symptomatic hypoglycaemia. Risk of hypoglycaemia was significantly lower with basal insulin alone than with other insulin strategies including premixed insulin and short-acting insulin alone. Non-intensive versus intensive insulin therapy and physical inactivity versus activity were also associated with a lower rise of symptomatic hypoglycaemia.
Conclusion: In patients with T2DM recently initiated on insulin therapy, low BMI at insulin initiation, low HbA_{1c} and insulin regimen at 1 year, physical activity and use of intensive insulin therapy were significant risk factors for symptomatic hypoglycaemia. The use of basal insulin alone was associated with a lower risk of symptomatic hypoglycaemia than other insulin regimens.

Table: Multivariable model of risk factors for documented symptomatic hypoglycaemia

Variable	Odds ratio*	95% CI	p value
BMI (kg/m^2) at insulin initiation	0.968	[0.948; 0.988]	0.0021
Physical activity: no vs yes	0.735	[0.589; 0.917]	0.0063
Normalized HbA_{1c} (%) at 1 year	0.752	[0.687; 0.822]	<0.0001
Insulin used at 1 year			
Basal + short-acting vs basal alone	1.972	[1.412; 2.755]	<0.0001
Premixed insulin vs basal alone	1.730	[1.298; 2.307]	0.0002
Short-acting alone vs basal alone	1.766	[1.113; 2.802]	0.0158
Other insulin† vs basal alone	2.381	[1.336; 4.243]	0.0033
Intensified insulin therapy: yes vs no	1.424	[1.109; 1.830]	0.0057

*Odds ratios were adjusted for between-country differences; †Any insulin regimen not covered by the four other insulin categories; BMI=body mass index; CI=confidence interval

The average length of hospital stay for a hypoglycaemic event in patients diagnosed with type 1 diabetes mellitus and type 2 diabetes mellitus

G.H. Chamberlain, P.H. McEwan;
Cardiff Research Consortium L.t.d, Cardiff, United Kingdom.

Background and aims: Hypoglycemia, abnormally low blood glucose levels, can occur in patients diagnosed with both type 1 diabetes mellitus (T1DM) and type 2 diabetes mellitus (T2DM), and is often associated with intensive treatment strategies. The resulting outcomes range from hunger, dizziness and confusion, to seizure, unconsciousness and rarely, brain injury. Patients who experience a severe hypoglycemic event are commonly hospitalized and therefore contribute to the health service burden. The aim of this study was to determine and examine the comparative length of hospital stay associated with hypoglycemic events in patients with T1DM and T2DM.
Material and methods: Routine hospital data were obtained from the Hospital Episode Statistics (HES) data warehouse, which contains anonymized, continuously collected data from all English hospitals. All patients with a primary diagnosis of hypoglycemia (ICD10 E162) between 1999 and 2006 were selected. Only a patient's first hypoglycemic event was included in the study, subsequent events were removed. Patients were subsequently categorized according to their type of diabetes using previous hospital admission definitions within the time period; T1DM (ICD10 E10) or T2DM (ICD10 E11). Patients whose history included a diagnosis of both T1DM and T2DM were removed from the study. The single outcome measure was length of hospital stay in days.
Results: The number of patients experiencing a hypoglycemic event within the dataset was 15,995 for T1DM and 21,736 for T2DM. Patients with T2DM were associated with significantly (p<0.0001) longer mean length of hospital stay for hypoglycemic their events (6.0 days; SD 8.9), compared to those with T1DM (3.2 days; SD 11.1).
Conclusion: The mean length of hospital stay associated with hypoglycemic events was 88% greater for those patients diagnosed with T2DM when compared to patients diagnosed with T1DM. Use of therapies for T2DM that are associated with a reduced risk of hypoglycemia can reduce the number of hypoglycemic events in these patients, and consequentially reduce length of hospital stay, and ultimately the burden to the health service.

579

Severe sulphonylurea-induced hypoglycaemia - a problem of uncritical prescription and deficiencies of diabetes care in geriatric patients

A. Holstein[1], C. Hammer[1], M. Hahn[1], N.-S. Kulamadayil[1], P. Kovacs[2];
[1]1st Department of Medicine, Klinikum-Lippe, Detmold, Germany,
[2]Interdisciplinary Center of Clinical Research, University of Leipzig, Germany.

Background and aims: Severe sulphonylurea-induced hypoglycaemia (SH) remains a life-threatening and underreported condition. We investigated the incidence of SH and clinical characteristics of patients with type 2 diabetes mellitus (T2DM) to demonstrate typical risk constellations.
Materials and methods: In a population based observational study, all consecutive cases of SH in the period 2000-2009 in a German area with 200.000 inhabitants were registered. Severe hypoglycaemia was defined as a symptomatic event requiring treatment with intravenous glucose and was confirmed by a blood glucose measurement of <50 mg/dl.
Results: A total of 1.419 cases of severe hypoglycaemia, 141 (10%) of them having been treated with sulphonylureas, were registered among the 103.256 patients who attended the medical emergency department. A mean incidence of 7 episodes of SH per year and 100.000 inhabitants was registered. The 139 hypoglycaemic individuals with T2DM (mean plasma glucose level of 31±10 mg/dl) had been treated with glimepiride (n=98), glibenclamide (n=40) or gliquidone (n=1). Neither preparation showed a constant dose-effect relationship, SH occurring within a wide dose range. The patients were characterised as follows: age 77.5±9.4 years, duration of diabetes 11±7 years, BMI 26.3±4.9 kg/m2, HbA1c 6.6±1.3%, creatinine clearance 46±24 ml/min. with renal insufficiency in 73%, comedication 7±3 drugs. 27% of patients with SH received additional drugs which were also main substrates of CYP2C9 the genetically polymorphic cytochrome P450 enzyme being responsible for the hepatic metabolism of SUs. In particular, they received torasemide, clopidogrel, phenprocoumon, diclofenac, phenytoine or fluvastatine. Two third of all subjects lived independently at home whereas one third was cared for by a home nursing service or received care in nursing homes. 30% had participated in diabetes education programs. In 31% systematic blood glucose monitoring was performed.
Conclusion: The tight glycaemic control (HbA1c 6.6%) in our patients can be regarded as highly predictive for recurrent antecedent hypoglycaemic episodes that were not perceived either by the patients themselves or by their relatives or care staff. Uncritical prescription of sulphonylureas neglecting crucial contraindications - particularly renal insufficiency - and deficiencies of diabetes care contributed substantially to the risk of SH in the mainly geriatric patients. There is a need for alternative therapeutic concepts that minimize the risk of hypoglycaemia in geriatric patients with T2DM.

580

The PANORAMA pan-European Survey: impact of severe and non-severe hypoglycaemia on quality of life and other patient reported outcomes in patients with type 2 diabetes

C. Bradley[1], E. Eschwège[2], P. de Pablos-Velasco[3], K.G. Parhofer[4], D. Simon[5], M. Tafalla[6], E. Pascual[6], L.A. Gönder-Frederick[7];
[1]Royal Holloway, University of London, United Kingdom, [2]INSERM U-1018, Paris, France, [3]Dr Negrin Hospital, Las Palmas University, Spain, [4]Klinikum der Universität, München, Germany, [5]Hôpital de la Pitié / INSERM U-1018, Paris, France, [6]AstraZeneca, Madrid, Spain, [7]University of Virginia, Health System, USA.

Background and aims: Hypoglycaemia is a side effect of glucose-lowering treatment that can cause distress and injury, and may damage quality of life (QoL) in patients with type 2 diabetes (T2D). PANORAMA is a large pan-European cross-sectional survey (NCT00916513) aimed at assessing patient reported outcomes in patients with T2D treated with glucose-lowering therapies. The present analysis compares data on QoL, treatment satisfaction and fear of hypoglycaemia in patients with T2D in relation to their experience of hypoglycaemia.
Materials and methods: Patients with T2D were randomly or consecutively selected from physician practices (mainly in primary care) in 8 countries (Belgium, Germany, Greece, Italy, the Netherlands, Spain, Turkey, and the UK). Eligible patients were ≥40 years of age, with a diagnosis of T2D for >1 year prior to study entry and an available medical record at the clinic of >1 year. All patients received dietary and exercise advice. Most patients were also being treated with either oral hypoglycaemic agents (OHAs) or injectables (insulin and GLP-1 receptor analogues) with or without OHAs. Treatment type was unchanged in the previous 3 months. Patients completed the Audit of Diabetes-Dependent Quality of Life (ADDQoL), Diabetes Treatment Satisfaction Questionnaire (DTSQ) and the worry subscale of the Hypoglycaemic Fear Survey-II (HFS-II). Data on history of severe and non-severe hypoglycaemic episodes were collected.
Results: 5,156 patients were included in the study between June and November 2009: 47.8% women; mean age 65.9 years (SD 10.3). Mean time since diagnosis was 9.0 years (SD 7.4). Patients who had experienced at least one episode of severe hypoglycaemia in the past 12 months showed significantly more negative impact of diabetes on QoL (ADDQoL, p<0.001), less satisfaction with treatment (DTSQ, p=0.004) and greater fear of hypoglycaemia (HFS-II, p<0.001) than patients who had not experienced severe hypoglycaemia. Similar differences were found on all three measures for a comparison of patients who experienced more than one episode of non-severe hypogly-

caemia per month with those who experienced one or fewer episodes per month (all p<0.001).
Conclusion: The occurrence of both severe and non-severe hypoglycaemia in T2D is associated with greater negative impact of diabetes on QoL, less treatment satisfaction, and greater fear of hypoglycaemia, and may be an important barrier to optimal glycaemic control in some patients.

Mean (SD) ADDQoL average weighted impact score, DTSQ treatment satisfaction score and HFS-II fear of hypoglycaemia score for patients who experienced ≥1 vs 0 episodes of severe hypoglycaemia, and patients who experienced >1 vs ≤1 episodes of non-severe hypoglycaemia in the last year

Episodes of hypoglycaemia in past 12 months	n	Mean (SD) score		
		ADDQoL[$]	DTSQ^	HFS-II[§]
≥1 severe	313	-1.0 (0.6)	26.3 (7.0)	30.4 (18.1)
0 severe	4,831	-0.6 (0.5)	30.1 (6.0)	12.9 (15.3)
Difference[1]		-0.22**	-1.14*	10.26**
>1 non-severe/month	889	-0.8 (0.6)	28.2 (6.8)	21.9 (17.7)
≤1 non-severe/month	4,258	-0.6 (0.5)	30.2 (5.9)	12.2 (15.1)
Difference[2]		-0.18**	-1.07**	7.34**

[$]average weighted impact score: range -9 (most negative impact) to +3 (most positive impact of diabetes on QoL); ^range 36 (very satisfied) to 0 (very dissatisfied); [§]range 72 (most fearful) to 0 (least fearful)
[1]Patients with ≥1 episode of severe hypoglycaemia - patients with 0 episodes of severe hypoglycaemia.
[2]Patients with >1 non-severe hypoglycaemic episode/month - patients with ≤1 non-severe hypoglycaemic episode/month.

PS 41 Mechanisms in hypoglycaemia

581

Effect of erythropoietin on cognitive performance, symptoms and counter-regulation during hypoglycaemia in patients with type 1 diabetes
P.L. Kristensen[1], U. Pedersen-Bjergaard[1], N.V. Olsen[2], B. Thorsteinsson[1,3];
[1]Department of Cardiology and Endocrinology, Hillerød Hospital, [2]Department of Neuroanaesthesia, Copenhagen University Hospital (Rigshospitalet), [3]University of Copenhagen, Denmark.

Background and aims: The incidence of severe hypoglycaemia in type 1 diabetes has not decreased over the past decades. New treatment modalities to minimise episodes of hypoglycaemia and attenuate hypoglycaemic cognitive dysfunction are needed. We studied if treatment with the potentially neuroprotective hormone erythropoietin (EPO) enhances cognitive function during hypoglycaemia.
Materials and methods: Eleven type 1 diabetic subjects with hypoglycaemia unawareness and at least two episodes of severe hypoglycaemia in the last year underwent a double-blind, randomised, balanced, cross-over study evaluating the effect of 40.000 IU of EPO on cognitive function, hypoglycaemic symptoms and counter-regulatory response during clamped hypoglycaemia. EPO or placebo were injected intravenously six days before the two experiments which were separated by at least six weeks. Two reaction time tests (CalCAP), Stroop's Colour and Word Test and a Trail Making Test (TMT) were used to evaluate cognitive function. The effects of EPO on cognitive function, hypoglycaemic symptoms and counter-regulatory hormones were assessed by analysis of covariance with baseline values and blood glucose during hypoglycaemia as co-variates.
Results: Mean (SD) plasma glucose concentration during hypoglycaemia was 2.2 (0.3) mmol/l on the EPO day and 2.0 (0.3) mmol/l on the placebo day (p=0.17). Compared with placebo, EPO treatment was associated with (parameter estimate (95% C.I.): a) reduction in the two reaction times during hypoglycaemia: 5 msec (-79 - 68; p=0.88) and 44 msec (-91 - 4; p=0.07); b) reduction in errors in the two reaction time tests: 0.3 (-1.4 - 2.1; p=0.68) and 4.1 (-7.4 - -0.9; p=0.017); c) increase in completed items in Stroop's Word, Colour and Word-Colour Test: 2 (-6 - 11; p=0.58), 1 (-6 - 8; p=0.71), and 2 (-4 - 7; p=0.51), respectively; d) reduction in completion time in TMT: 3 sec (-45 - 40; p=0.88); and e) reduced neuroglycopenic and autonomic symptom scores: -0.9 points (-3.8 - 2.0 points; p=0.46) and -0.6 points (-5.5 - 4.3; p=0.8), respectively. Peak values of adrenaline, cortisol, growth hormone and glucagon did not differ between EPO and placebo days.
Conclusion: In patients with type 1 diabetes and hypoglycaemia unawareness, treatment with EPO is associated with a beneficial effect on cognitive function in only one of six tests of cognitive function. Hypoglycaemic and counter-regulatory hormonal responses were not changed by EPO treatment. However, it cannot be ruled out that alternative timing and dosage of EPO or new non-erythropoietic EPO analogues may be more efficient in enhancing cognitive function during hypoglycaemia.

The effect of diabetes and its control on susceptibility to learned helplessness in streptozotocin-induced diabetes rats
Y. Go[1], H. Kitaoka[2];
[1]Internal medicine, Seikeikai Hospital, Sakai City Osaka, [2]Internal medicine, Seikeikai Hospital, Sakai City, Japan.

Aims: In order to examine the mechanism linking diabetes to depression, specifically whether diabetic rats in good glycemic control versus those in hyperglycemic, or subject to exposed alternative periods of hyper and hypoglycemia, are different at risk of affective disorder. We induced learned helplessness, as model of depression, is indicated the rate of cognitive processing.
Methods: Using the streptzotocin rats receiving insulin NPH or saline, totally 37 rats, were divided into 4 types of glycemic control groups, Group A (good), B (hypo-hyper) ,C (untreated), D (controls). The bodyweight, the blood glucose concentration and HbA1c were measured. And all animals were placed in a learned helplessness paradigm, Forced swimming test (FST): the scorer would rate the rat's behavior each 5 second period, as one of the following four behaviors: immobility and another action. We examined the differences in the length of immobility (a key marker of learned helplessness) with the analysis using Tukey-Kramer multiple comparison.

Results: Glycemic control: Group A had nearly kept smaller change of blood glucose throughout the day. Group B of blood glucose showed a very steep fall from 475.8 ± 193.2 (mean ± SD) mg/dl to 42.8 ± 22.6 mg/dl within three hours after the insulin injection. Mean HbA1c of the diabetic group without insulin treatment significantly increased from 5.9 ± 1.3 to 8.7 ± 4.0 % ($p < 0.0001$). In diabetic groups receiving insulin injection once a day or twice a day, the level of HbA1c significantly decreased from 5.6 ± 1.0 to 3.8 ± 0.6 % and 6.4 ± 1.7 to 3.7 ± 0.5 % respectively. There was no difference in the levels of HbA1c before treatment and after treatment between the groups with one daily injection and two daily injection of insulin. The bodyweight in A and B groups was not significantly different compared with that in non diabetic control group ($P = 0.001, 0.001$). Group C is significantly low compared with that in Group D (< 0.0001). FST: There were trends for counts of immobility to be higher in all 3 diabetic groups compared to Group D, especially in Group B, the mean count of immobility is significantly high compared with Group D (< 0.001). There is no significant difference between 4 groups in the mean counts of swimming. The climbing was significantly low in Group C compared to Group D (< 0.001).
Conclusion: The rats which had been exposed to hypoglycemia and hyperglycemia are more likely to develop learned helplessness than good glycemic control rats. These investigations are thought to be interesting to examine the relationship between diabetes and depression, and suggested that acute varieties in glycemic control could be the mechanism of susceptibility to affective disorder.

583

Physiological and performance differences between drivers with type 1 diabetes with and without a history of recurrent hypoglycaemia driving mishaps

D.J. Cox[1], B.P. Kovatchev[1], H. Singh[1], L.K. Campbell[2], L.A. Gonder-Frederick[1];
[1]Psychiatry & Neurobehavioral Sciences, University of Virginia Health System, Charlottesville, [2]Department of Psychiatry and Behavioral Sciences, Medical University of South Carolina, Charleston, USA.

Background and aims: In Europe and the U.S. collisions are more than twice as common among drivers with type 1 diabetes (T1DM) than spouses who do not have diabetes. This increased risk appears to be attributable to a subgroup of drivers with T1DM. The hypothesis tested is that this vulnerable subgroup is more at risk for hypoglycemia and its disruptive effects on driving ability.
Materials and methods: Thirty-eight drivers with Type 1 diabetes, 16 with (+History) and 22 without (-History) a recent history of recurrent hypoglycemia-related driving mishaps, drove a virtual reality driving simulator and watched a videotape of someone else driving a simulator for 30 minute periods. Driving and video testing occurred in a double-blind, randomized, crossover manner during euglycemia (5.5 mmol/L) and progressive hypoglycemia (3.9 down to 2.5 mmol/L). Subjects completed a brief neuropsychological test battery pre and post the euglycemia trial, and during the hypoglycemia trial they completed the battery at euglycemia immediately before and after and at hypoglycemic naidar. Examiners were blind to which subjects were +/-History, while subjects were blind to their blood glucose levels and targets.
Results: Groups did not differ on gender, driving history, HbA1c, insulin dose, BMI, hypoglycemia awareness or frequency of self-treatment during hypoglycemic driving in the laboratory study. +History subjects did report more episodes of severe hypoglycemia in the previous 12 months ($p<.03$). During euglycemia, +History participants reported more autonomic and neuroglycopenic symptoms ($p<.01$), performed worse on neuropsychological tests ($p<.01$) and tended to require more dextrose infusion to maintain euglycemia with the same insulin infusion ($p<.09$). During progressive hypoglycemia, these subjects demonstrated less epinephrine release ($p=.02$), greater driving impairments ($p=.03$), and performed worse on neuropsychological tests ($p<.01$).
Conclusion: Current findings support the speculation that there is a subgroup of type 1 diabetes drivers more vulnerable to experiencing hypoglycemia-related driving mishaps. This increased vulnerability may be due to possibly greater carbohydrate utilization, rendering them more vulnerable to experiencing hypoglycemia. During hypoglycemia they may release less hormonal counter-regulation, leading to more profound hypoglycemia, and more neuroglycopenia, rendering them more vulnerable to hypoglycemia-impaired driving. Such individuals may be counseled to treat pending or actual hypoglycemia more aggressively and early immediately before and during driving.

PHUn - Psychopathology of Hypoglycaemia Unawareness

H. Rogers[1], N. de Zoysa[2], S.A. Amiel[2];
[1]Diabetes Dept, King's College Hospital, London, [2]Diabetes Research Group, King's College London, United Kingdom.

Background and aims: A structured education programme teaching flexible insulin therapy to people with Type 1 diabetes (T1DM) demonstrated that hypoglycaemia awareness could be regained in 48% of hypoglycaemia-unaware patients who had attended a 5 day course. However neuroimaging data show abnormal reward responses in people with T1DM and hypoglycaemia unawareness (HU). And there remain 52% HU patients who do not regain awareness from education. Indeed, this group show less behaviour change with current educational strategies and are at high risk of severe hypoglycaemia. Our study was designed to examine the meanings people with HU assign to their condition. The study aims to: 1. use clinical interviews to identify cognitive biases; 2. construct a theoretical account which explains why the cognitive abnormality does not self-correct; 3. develop specialised psychological interventions to address the cognitive bias; 4. test the efficacy of the interventions in randomised controlled trials and 5. make the treatments more broadly available through dissemination studies. This abstract addresses the first 2 aims and further research is being carried out to address the latter.
Materials and methods: People with T1DM and HU underwent semi-structured interviews. Data were recorded and analysed using grounded theory principles and interviews continued until saturation (common themes recurring).
Results: 17 people (10 female, mean age 53.1±7 yrs) were interviewed to reach saturation. The common themes were identified and categorised, this lead to the development of a theory which proposes that individuals with HU can be placed into 1 of 5 groups. Group 1: people with T1DM who may not have received adequate education about HU and do not realise that awareness can be restored. Group 2: people with HU, but they are able to carry on life quite normally with no perceived clinical or quality of life disadvantage. They do not experience severe hypoglycaemia. Group 3: those who experience horrendous episodes of severe hypoglycaemia, which they perceive as frightening, disabling and/or deeply embarrassing socially, this group evaluate and act to regain awareness. Group 4: This group all have a cognitive bias preventing them from hearing and acting upon the cues. The biases manifest in their not being able to recognise or act on the danger in which HU places them. They realise they have HU but are not 'appropriately' worried about it. The cognitive biases fall into the following categories: (a) because they do not feel any symptoms, they do not act; (b) because of fear of complications they act on any high blood glucose levels; (c) they believe 'it won't happen again'; (d) there is a strong desire to be 'normal' so may not disclose HU; (e) they believe that severe hypoglycaemia is normal, part of their lives, so nothing need be done. Group 5. those who derive some secondary gain from having severe hypoglycaemia.
Conclusion: Factors underlying the known persistence of HU in a proportion of people with T1DM can be identified for individuals and fall into one of 5 categories. Identifying the factors operating in an individual will allow therapies to restore hypoglycaemia awareness to be tailored (eg Group 1 education; Group 3 increased monitoring technology; Group 4 a psychological intervention) to their situation and help more people with T1 regain their endogenous defences against severe hypoglycaemia.

Variable recovery from hypoglycaemic encephalopathy following massive insulin overdose in type 1 diabetes

C. Ballav, A. Cairns, J. Heritage, S. Kotnis, H. Brain;
Diabetes and Endocrinology, Buckinghamshire Hospitals NHS Trust, High Wycombe, United Kingdom.

Background and aims: To describe and compare the clinical course of three male type 1 diabetes patients admitted to the Intensive Care Unit with hypoglycaemic encephalopathy following massive Insulin overdose, in light of available evidence.
Materials and methods: We compare outcome at 6 weeks following hypoglycaemic encephalopathy from insulin overdose and make a retrospective analysis of clinical course in the first week of admission. A review of the literature looking at the incidence, pathogenesis of hypoglycaemic encephalopathy and predictors of outcome in massive insulin overdose.

Results: Of 64 attendances for hypoglycaemia in 12 months, 3 patients (4.69%) had hypoglycaemic encephalopathy, from insulin overdose. In 2 patients the overdose was deliberate, with no previous history of depression. The patients had mean age of 37.6 years (range 32 - 41 years), with a mean capillary glucose of 2.26mmols/l (range 1.4 - 3mmol/l) at presentation. The mean interval between presentation following insulin overdose and initiation of treatment was 4.3 hours (range 1 - 8 hours). Glucagon was administered to all 3 patients and the mean glucose infused was 175g (range 50g - 425g). The mean duration of mechanical ventilation was 63 hours (range 0 - 120 hours). The outcome at 6 weeks was persistent vegetative state and death in the patient requiring maximum duration of mechanical ventilation, loss of recent memory with partial recovery at 6 weeks in the second and loss of higher cortical functions with partial recovery at 6 weeks in the third patient. The most severe outcome was in the patient requiring maximum amount of glucose and mechanical ventilation. The clinical outcome was not related to the severity of hypoglycaemia at diagnosis.
Conclusion: Hypoglycaemic encephalopathy from insulin overdose is rare. The severity of clinical outcome correlated with the interval between overdose and start of treatment, amount of glucose infused and duration of mechanical ventilation. This is in keeping with existing evidence on prognostic indicators in patients with hypoglycaemic encephalopathy and may be used to predict outcomes in acute setting.

586

Detection of hypoglycaemia associated EEG-changes during sleep in type 1 diabetes

L. Folkestad[1], R. Elsborg[2], L. Remvig[2], H. Beck-Nielsen[3], B. Thorsteinsson[4], P. Jennum[5], M.D. Gjerstad[5], C. Juhl[2];
[1]Sydvestjysk Sygehus Esbjerg, [2]Hyposafe, Lyngby, [3]Odense Universitets Hospital, [4]Hillerød Hospital, Hillerød, Denmark, [5]Glostrup Hospital, Denmark.

Background and aims: Nocturnal hypoglycemia is a feared complication to insulin treated diabetes and is often the limiting factor for further intensification of treatment. Hypoglycemia unawareness, being increasingly common with tight metabolic control and long diabetes regulation, increases the risk of severe hypoglycemia. Slow wave electroencephalogram (EEG) patterns can be demonstrated during episodes of daytime hypoglycemia, and real-time detection of specific EEG changes may constitute a novel technique for a hypoglycemia alarm. Sleep EEG diverges significantly from daytime EEG including episodic occurrence of slow wave patterns. The present study tests the hypothesis that specific hypoglycemia associated EEG changes also occur during sleep, and that these can be detected in time for the patient to take action.
Materials and methods: Ten type 1 diabetes patients (mean age 47 years, diabetes duration 23,7 years, HbA1c 7.5%) all suffering from hypoglycemia unawareness, were subjected to induced hypoglycemia by graded insulin infusion both during daytime and sleep. One patient dropped out after the first night experiment. EEG was recorded from a single electrode with three measuring points placed subcutaneously at the temporal region and was analyzed real-time by an automated multi-parameter algorithm based on EEG frequency, amplitude and several other features derived from pilot experiments. The patients received an auditory alarm when EEG-changes met a predefined threshold. The patients were instructed beforehand to consume a sandwich and a juice at the time of alarm. If blood glucose fell to 1.7mmol/l without alarm, hypoglycemia was ceased. To explore intraindividual variability, the subjects were exposed to an additional night with identical study procedures but no alarm was given.
Results: Seven out of nine patients developed hypoglycemia associated EEG-changes during daytime (mean blood glucose (BG) 2.7mmol/l) of which six were able to revert hypoglycemia by carbohydrate ingestion. During sleep nine out of ten developed EEG-changes (mean BG 2,0mmol/l) and eight woke up due to the alarm. Four corrected hypoglycemia by ingestion (mean BG 2,2mmol/l) while the remaining four (mean BG 1,9mmol/l) was supplemented with glucose due to cognitive impairment. Only two events of false alarm were recorded. EEG was analyzed according to the American Academy of Sleep scoring manual to determine sleep stages. Hypoglycemia associated EEG changes occurred irrespective of the sleep stages and overruled physiological sleep related patterns.
Conclusion: We conclude that automated real-time analysis of EEG is a possible method to warn diabetes patients of impending hypoglycemia both during daytime and sleep. Post hoc improvement of the algorithm indicates that earlier detection of hypoglycemia may be possible, which will improve the sensitivity of the alarm.

PS 42 Hypoglycaemia - screening and management

587

Management of hypoglycaemia in a tertiary inpatient centre: clinical audit

S.G. Wijetilleka, K.P. Lim, E. Chinnasamy, I. Malik, A. Flanagan, A. Panahloo, N.H. Patel;
Diabetes & Endocrinology, St George's Hospital, London, United Kingdom.

Background and aims: Treatment-induced hypoglycemia causes recurrent morbidity and mortality in patients with type 1 diabetes mellitus (T1DM) and advanced type 2 diabetes mellitus (T2DM). The ACCORD study showed that patients with cardiovascular disease over an average of 3.5 years of treatment, 22% more patients from the intensively-controlled blood glucose group died. The rate of death in the intensive group, who experienced 3 times as many severe hypoglycaemic episodes compared to the standard-treatment group, is statistically significant. Profound hypoglycaemia causes neurological damage and can be fatal. In June 2009, an audit examining the identification and management of inpatient hypoglycaemic episodes was performed at St. George's Hospital. The aim of this audit was to compare current practice against good practice guidelines. Management was shown to be sub-optimal so a trustwide Hypobox and ward-based teaching sessions were commenced. A re-audit was performed to demonstrate subsequent changes and improvements in practice.
Materials and methods: 8 wards (5 medical, 1 cardiology, 2 surgical) were visited daily for one week. The diabetic charts of all patients on the ward were reviewed for episodes of hypoglycemia, how patients perceived them and how these were managed. We looked at whether efforts were made to identify the reason for the hypoglycaemic episode and whether steps were taken towards preventing a recurrence.
Results: The average age was 74 years. Mean CBG at time of hypoglycaemic episode was 3.2 mmol/L. Majority of episodes (75.6%) of hypoglycemia were mild where 95.5% had a GCS of 15/15. The remaining 24.4% of episodes were moderate (1.5 - 2.5 mmol/l). 96% of hypoglycaemic episodes were detected on routine diabetic CBG monitoring, 72% of hypoglycaemic episodes occurred between 2200 and 0600 hours. 31% of episodes were corrected according to trust guidelines appropriate for the CBG and GCS, 87.5% had their CBG rechecked. 11.1% of patients had reasons for their hypoglycaemia identified and steps were taken in 8.9 % of patients to prevent further episodes.
Comparison with the original audit: The original audit showed that only 58.3% of patients had their capillary blood glucose checked within fifteen minutes of commencing treatment for hypoglycaemia. Only 20% of patients received fast-acting carbohydrate as a treatment measure. Attempts took place to identify the cause of hypoglycaemia in one sixth of hypoglycaemic episodes, with just 12.5% of patients having steps taken to prevent the recurrence of hypoglycaemia. With the re-audit, there has been some improvement with 87% of CBGs checked post-treatment and the types of treatment used (31% from Hypobox).
Conclusion: Compared to the initial audit, improvements have been made with the products used to treat hypoglycaemia and the monitoring of patients post-treatment. Identifying and preventing the causes of hypoglycaemia remains problematic despite provision of the Hypobox and protocols. Staff awareness of hypoglycaemia guidelines is the crucial factor in ensuring patients receive optimal management and prevention of hypoglycaemic episodes. Further teaching with audit data is required.

588

Fear of hypoglycaemia - how to identify patients at risk in a routine clinical practice?

K. Kanc[1], A. Kastrin[2], M. Kastrin[1], L.A. Gonder-Frederick[3];
[1]Diabetes&Me (jazindiabetes), Private Diabetes Centre, Ljubljana, Slovenia, [2]Institute of Medical Genetics, University Medical Centre, Ljubljana, Slovenia, [3]University of Virginia, Virginia, USA

Background and aims: Hypoglycaemia is a frequent experience in people with insulin-treated diabetes mellitus and may lead to the development of fear of hypoglycaemia (FoH). This condition may be often overlooked, causing emotional and behavioral changes that can jeopardize daily life with diabetes as well as future development of diabetes complications. The aim of the study is to explore the relation of FoH to diabetes regulation, diabetes-related

problems and the awareness of hypoglycaemia in persons with type 1 (T1D) and type 2 diabetes (T2D).
Materials and methods: All insulin-treated patients ($N = 140$) registered with private diabetes centre at the time of study were contacted and 114 agreed to participate (56 males, 58 females). Age varied across sample from 15 to 88 years with a mean age of 53 (±19) years; mean ages of T1D (30 CSII and 23 MDI-treated) and T2D (61) patient subgroups were 39 years (±15) and 65 years (±13), respectively. Patients completed the Hypoglycaemia Fear Survey (HFS) and the Problem Areas in Diabetes (PAID) questionnaires. Hypoglycemia awareness status was assessed by Clarke's questionnaire. We confirmed high internal consistency reliability of the translated questionnaires (Cronbach's alphas were 0.93, 0.94, and 0.49 for HFS, PAID, and Clarke's questionnaire, respectively). Wilcoxon test (W) was used to evaluate differences between independent groups as appropriate. Metabolic control was assessed by measuring glycated haemoglobin A1c (HbA1c).
Results: Statistically significant differences across gender were found for the HFS score (Total scale: $W = 1179$, $p = 0.012$; Worry subscale: $W = 1122$, $p = 0.004$) and PAID score ($W = 1106$, $p = 0.003$), indicating greater FoH and inadequate emotional response to diabetes in females. HFS score was significantly higher in T1D in comparison to T2D patients (Total scale: $W = 2021$, $p = 0.022$; Worry subscale: $W = 2094$, $p = 0.007$). Comparing therapy regimen for T1D patients, we found significant differences for the HFS Behavior subscale score ($W = 212$, $p = 0.014$) in MDI, implying greater behavior-related FoH in MDI-treated patients. Significant correlation between HFS and PAID scores ($r = 0.70$, $p < 0.001$) indicate that FoH increases with more diabetic problems. In addition, significant correlation was found between HFS score and Clarke's score in general ($r = 0.20$, $p = 0.030$), T2D ($r = 0.27$, $p = 0.036$), T1D ($r = 0.17$, $p = 0.217$), meaning that patients with T2D experience an increase in FoH as their awareness decreases. Bivariate correlations with questionnaire scores and HbA1c level found significant association of HbA1c with HFS score ($r = 0.23$, $p = 0.015$) and PAID score ($r = 0.47$, $p < 0.001$), indicating worse glucose control with increasing FoH and diabetes problems. On the contrary, four patients had very high PAID and HFS score and low HbA1c.
Conclusion: In particular MDI-treated women with T1D, bad glycaemic regulation and lower awareness of hypoglycaemia need clinical attention, focused on hypoglycaemia. Patients with excellent glycaemic control, combined with great FoH and pronounced diabetes-related problems however, should not be overlooked.

589

Nature of association between severe hypoglycaemia and risks of vascular events and death in ADVANCE

B.E. De Galan[1,2], S. Zoungas[2,3], A. Patel[2], Q. Li[2], L. Billot[2], M. Woodward[2,4], J. Chalmers[2], B. Neal[2], S. MacMahon[2], D. Grobbee[5,6], S.R. Heller[7];
[1]Medicine, Radboud University Nijmegen Medical Centre, Netherlands, [2]The George Institute for International Health, Sydney, Australia, [3]Monash University, Melbourne, Australia, [4]Mount Sinai School of Medicine, New York, USA, [5]Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands, [6]Sheffield Teaching Hospitals National Health Service Foundation Trust, United Kingdom, [7]University of Sheffield, United Kingdom.

Background and aims: The present analyses were performed to explore the risk factors for severe hypoglycaemia associated with glucose control and to examine the relationship between severe hypoglycaemia and major clinical outcomes in patients with type 2 diabetes participating in the Action in Diabetes and Vascular disease: Preterax and Diamicron Modified Release Controlled Evaluation (ADVANCE) trial.
Materials and methods: Baseline factors predicting severe hypoglycaemia were assessed. Associations between severe hypoglycaemia and major macrovascular or microvascular events and death were examined with Cox proportional hazards models, adjusting for baseline and post randomization covariates.
Results: Over a median of 5-years of follow-up, 231 patients (2.1%) experienced severe hypoglycaemia, a considerably lower rate than reported in other large-scale trials of intensive glucose control. Baseline factors associated with severe hypoglycaemia were age, diabetes duration, history of microvascular disease, kidney dysfunction, smoking, BMI, HbA1c, education level, cognitive dysfunction, combination anti-hyperglycaemic therapy and assignment to intensive glucose control (all $p < 0.05$). The median times from the first severe hypoglycaemia to first major macrovascular event, microvascular event or death were 1.56 years (IQR = 0.84, 2.41 years), 0.99 years (IQR = 0.40, 2.17 years) and 1.05 years (IQR = 0.34, 2.41 years) respectively. During follow up, adjusted risks of major macrovascular events (HR 2.88, 95% CI 2.01-4.12), major microvascular events (HR 1.81, 95% CI 1.19-2.74), cardiovascular death (HR 2.68, 95% CI 1.72-4.19) and all-cause death (HR 2.69, 95% CI 1.97-3.67) were significantly increased among those experiencing prior severe hypoglycaemia compared to those who did not (all $p < 0.0001$). Similar associations were also apparent for a range of non-vascular outcomes including respiratory, digestive system and skin events (all $p < 0.01$). When the analyses were performed stratified by treatment allocation, the results remained essentially unchanged.
Conclusion: Severe hypoglycaemia was strongly associated with increased risks of diverse major clinical outcomes, but not temporally related. Severe hypoglycaemia appears to be a marker of vulnerability for rather than a direct cause of adverse clinical outcomes. The complex interplay of confounding factors makes attribution of causation difficult.

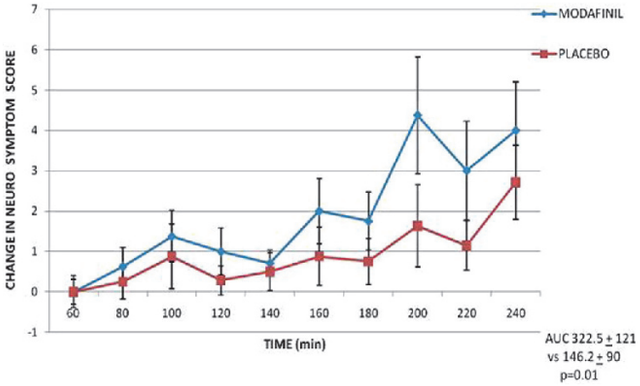
The effect of modafinil on counterregulatory and cognitive responses to experimental hypoglycaemia in type 1 diabetic patients with hypoglycaemia unawareness

P. Thomakos, M.M. Teh, Y. Samarasighe, A. Pernet, B. Wilson, P. Choudhary, S.A. Amiel;
Diabetes Research Group, King's College School of Medicine, London, United Kingdom.

Background and aims: Patients with Type 1 diabetes rely on symptoms of hypoglycaemia to detect hypoglycaemia and take corrective action before blood glucose drops low enough to impair cognitive function or consciousness. Repeated hypoglycaemia can impair hypoglycaemia awareness increasing the risk of severe hypoglycaemia 3-6 fold. Modafinil reduces the release of the inhibitory brain neurotransmitter GABA and improves adrenergic sensitivity and some aspects of cognitive function at hypoglycaemia in normal individuals. We aimed to assess the effect of modafinil on cognitive function as well as symptomatic and hormonal responses to hypoglycaemia.
Material and methods: Eight individuals with type 1 diabetes and hypoglycaemia unawareness (mean age 47+10 years, BMI 24.3+2.5 kg/m2, HbA1c 6.6+0.9, duration of diabetes 29+12.3 years) received, in random order, two 100-mg doses of modafinil or placebo, followed by a paired hypoglycaemic clamp study in which plasma glucose was reduced stepwise to 5.0, 4.4, 3.8, 3.4, 2.8 and 2.4mmol/l. Catecholamines, symptom scores and cognitive function were measured throughout. Subjects rated neuroglycopenic (difficulty speaking, confusion, dizziness, irritability, blurred vision and drowsiness) and autonomic symptoms (sweating, anxiety, tremor, palpitations, feeling hot and tingling) on a visual analogue scale on which patients graded the symptoms from 1 (absent) to 7 (very severe) at 20 minutes intervals. Four-choice reaction time, Digit Symbol Substitution Test, Stroop Black-White, Colour-X reading and Colour-Word interference test were administered at each step.
Results: Neuroglycopenic symptoms of hypoglycaemia were experienced at higher glucose level with modafinil [mean 2.7+0.6 vs 2.3+0.4 mmol/l; p=0.025], and to a greater degree [area under curve for neuroglycopenic symptoms corrected for baseline 322.5+121 vs 146.2+90; p=0.01] (see figure) with a higher peak score [peak-baseline neuroglycopenic symptom score 4.12+3.3 vs 2.62+2.5; p=0.009]. There were no differences in autonomic symptom responses. There were no differences in glucose thresholds, area under the curve or peak levels for catecholamine responses to hypoglycaemia. Despite higher neuroglycopenic scores there was no difference in glucose thresholds or degree of deterioration in cognitive function tests.
Conclusion: The use of modafinil was associated with generation of warning symptoms of hypoglycaemia at higher glucose level and to a greater degree than placebo although there was no difference in hormonal responses or cognitive dysfunction. The data support a role for disinhibition of GABAergic neurons in the generation of neuroglycopenic symptoms in hypoglycaemia which may be reversible, but imply a different sensitivity or involvement of other pathways in other aspects of the normal counterregulatory response.



591

Risk of hypoglycaemias and hypoglycaemia prevention behaving in type 1 diabetic patients - results of continuous glucose monitoring and Gravelling´s questionaire - a pilot study

J. Broz[1], J. Polak[1], E. Silhova[1], V. Donicova[2];
[1]3rd medical Faculty, Charles University, Prague, Czech Republic, [2]Private Department of Diabetology, Internal Medicine and Metabolism, Košice, Slovakia.

Background and aims: Hypoglycemic episode during driving could cause a fatal incident. Using a continuous glucose monitoring in type 1 diabetic patients we wanted to determine the glycemic excursions during periods of driving.
Materials and methods: We monitored 12 patients with type 1 diabetes mellitus treated with intensified insulin regimen (7 men, 5 woman), duration of disease 11,2 ± 5,2 year. Each patient wore a CGMS for 3-5 working days during his normal activity and was not alowed to see actual glycaemic values. Patients were asked to record all important events (such as insulin injection, exercise, meals, working periods) including periods of a car driving. After CMGS use, continuous glucose profiles were reviewed to identify glycaemic excursion during periods of car driving with a special interest in hypoglycaemic episodes (values under 3,5 mmol/l) and periods of glycemias under 4,5 mmol/l with considerable risk of hypoglycaemia. Each patient complete Gravelling´s questionnaire.
Results: We evaluated 2772 min (46 hours 12 min) of driving, an average 77 ± 27,3 per day and patient. Patients recorded 2 symptomatic episodes while driving. We found 7 episodes of asymptomatic hypoglyceamias, all in 2 patients. Total duration of period with glycaemia under 4,5 was 132 min (4,8% of total driving time).Total duration of period with glycemia under 3,5 was 22 min (0,8% of total driving time). Selected results from questionaire: 2 patients almost never measure glycemia before or during driving, none of them stops after hypoglycemia for longer than 45 min.
Conclusion: Risk of hypoglycaemia even in well experienced patients with type 1 diabetes mellitus during driving is considerable and should be regularly focused in education.

592

Prevalence and risk factors of hypoglycaemia unawareness and severe hypoglycaemia in patients with type 1 diabetes

T. A'Campo[1], B. Schouwenberg[1], B. Veldman[2], C.J. Tack[3], P. Smits[1], B.E. De Galan[3];
[1]Departments of Pharmacology -Toxicology, Radboud University Nijmegen Medical Centre, [2]Department of Internal Medicine, Canisius Wilhelmina Hospital, [3]Department of Internal Medicine, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: Hypoglycaemia is the most frequent adverse effect of insulin therapy in patients with type 1 diabetes (T1DM). Repeated episodes of hypoglycaemia may lead to hypoglycaemia unawareness (HU), which in turn is a risk factor for severe hypoglycaemia (SH). Modern insulin analogues and insulin pump therapy, which are associated with lower rates of hypoglycaemia, are being increasingly used. We therefore aimed to assess the prevalence of HU and SH in a contemporary cohort of T1DM patients and to identify potential risk factors.
Materials and methods: We performed a cross-sectional study of a cohort of 486 T1DM patients (47% male), who visited the outpatient clinic of a Dutch University Hospital between 2006 and 2008. All patients were asked to complete a Dutch translation of the Clarke questionnaire, where a score of 3 or more (out of 5) was assumed to indicate HU. SH was assessed on the basis of the same questionnaire. Clinical data on demographics, diabetes treatment, concurrent medication and vascular complications were retrieved from medical records. Unadjusted and adjusted Odds ratio's (OR) were calculated using binary logistic regression.
Results: The mean diabetes duration was 25 years, HbA1c averaged 7.9% and 89% used insulin analogues. 144 patients (30%) used insulin pumps. A total of 158 patients (33%) had a score indicating HU and 103 patients (21%) recalled SH in the year prior to the questionnaire. In unadjusted analyses, HU was associated with male sex, lower HbA1c, duration of diabetes, autonomic neuropathy and estimated GFR < 60ml/min/1.73m2 (all P < 0.05). After adjustments, duration of diabetes (OR per year 1.03; 95% CI: 1.01-1.05), estimated GFR < 60ml/min/1.73m2 (3.30; 1.20-9.10) and lower HbA1c (per % 1.49; 1.22-1.81) were still associated with HU. SH was independently associated with the presence of autonomic neuropathy (3.62; 1.65-7.94) and the use of benzodiazepines (4.59; 1.80-11.73), but not with HbA1c or diabetes duration. The use of insulin analogues, insulin pump therapy, ACE inhibitors or beta-blockers were not associated with either HU or SH.
Conclusion: HU is still highly prevalent in T1DM patients despite advances in insulin therapy. Diabetes duration, lower HbA1c level and kidney dysfunction were independent risk factors for HU. Autonomic neuropathy and use of benzodiazepines were risk factors for SH. Clinicians treating patients with T1DM should be aware of the still high prevalence of HU and its risk factors.

Odds ratio for hypoglycaemia unawareness and severe hypoglycemia

	Hypoglycaemia unawareness (HU)	Hypoglycaemia unawareness (HU)	Severe hypoglycaemia (SH)	Severe hypoglycaemia (SH)
	Unadjusted OR (95% CI)	Adjusted OR (95% CI)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Sex (male vs. female)	1.47 (1.00-2.15)	1.38 (0.92-2.07)	1.05 (0.68-1.62)	
Age (per year)	1.02 (1.01-1.04)	1.01 (0.99-1.03)	1.00 (0.98-1.01)	
HbA1c (per 1% lower)	1.40 (1.16-1.68)	1.49 (1.22-1.81)	1.08 (0.89-1.30)	
Diabetes duration (per year)	1.03 (1.02-1.05)	1.03 (1.01-1.05)	1.01 (0.99-1.02)

Effects of short-term continuous subcutaneous insulin infusion on insulin sensitivity and plasma FGF-21 levels in patients with new-onset type 2 diabetes mellitus

D. Jing[1], G. Yang[1], L. Li[2];
[1]Department of Endocrinology, [2]Department of Clinical Biochemistry, Chongqing Medical University, China.

Background and aims: FGF-21 is a recently described member of the FGF family that is highly expressed in adult mouse liver and thymus. Recent data have shown that FGF-21 is a potent regulator of glucose homeostasis. In the present study, we investigate the effects of short-term continuous subcutaneous insulin infusion(CSII) on insulin sensitivity and plasma FGF-21levels in patients with new-onset type 2 diabetes mellitus (T2DM). We also assessed the association between plasma FGF-21 body composition, and several metabolic parameters in these subjects.
Materials and methods: 30 patients with new-onset T2DM were treated with CSII for 2 weeks. A hyperinsulinemic-Euglycemic clamp was performed for determining insulin sensitivity in T2DM patients. The body composition was assesses. Blood samples were drawn after an overnight fast and Plasma insulin, FFA, HbA1c, TG, TC, LDL-C, HDL-C were measured. Plasma FGF-21 levels were measured with a radioimmunoassay. The homeostasis model assessment of insulin resistance (HOMAIR) and the homeostasis model assessment of β-cell insulin secretion (HOMAIS) were calculated. Plasma FGF-21 levels were measured by an ELISA.
Results: Fasting plasma FGF-21 levels were higher in T2DM than in controls (1.6±0.1 *vs.*1.1±0.4μg/L, P<0.01). After treatment with CSII, fasting blood glucose (FBG), HbA1c**,** fasting plasma insulin(FIns)and HOMA-$_{IR}$ were decreased significantly in T2DM (14.5±1.4 *vs.* 5.8±0.5 mmol/L, 10.4±1.2%*vs.*8.6±1.2%,16.79±2.75*vs.*12.87±5.71mU/L and 10.56±1.37 *vs.* 3.33±1.61 respectively, P<0.05 and P<0.01), while glucose infusion rate (GIR)was increased significantly (2.99±1.43 *vs.* 5.10±1.78 mg.kg^{-1}.min^{-1}, P<0.01). Fasting plasma FGF-21 levels were decreased significantly by CSII treatment (1.6±0.1 *vs.*1.3±0.1μg/L, P < 0.05).
Conclusion: Short-term CSII therapy can remarkably ameliorate insulin sensitivity and degrade plasma FGF-21 levels in T2DM patients. The change of plasma FGF-21 levels may be related to metabolic disturbance and insulin resistance.

Comparison of fasting apelin and visfatin levels between subjects with type 1 diabetes mellitus and controls and response after insulin administration

K. Alexiadou[1], A. Kokkinos[1], D. Perrea[2], C. Voulgari[1], S. Liatis[1], N. Katsilambros[1], N. Tentolouris[1];
[1]Laiko General Hospital, [2]Laboratory of Experimental Surgery and Surgical Research "N. S. Christeas", Athens, Greece.

Background and aims: Apelin and visfatin are two recently described adipokines. Experimental data have shown that apelin exerts important beneficial cardiovascular effects and its synthesis is stimulated by insulin. Visfatin is involved in the regulation of glucose homeostasis by binding to and activating the insulin receptor in a manner distinct from insulin. No data exist on differences in plasma concentrations of apelin and visfatin between subjects with type 1 diabetes mellitus (T1DM), a condition characterized by insulin deficiency, and healthy controls and on the effect of exogenous insulin administration on plasma concentrations of these adipokines. In the present study we examined differences in plasma apelin and visfatin concentrations between healthy controls and subjects with T1DM. Additionally, we studied the effect of a bolus insulin administration on plasma apelin and visfatin levels during an oral glucose tolerance test (OGTT) in patients with T1DM.
Materials and methods: A total of 120 subjects (60 with T1DM and 60 age, gender and body mass index matched-controls) were studied. Plasma apelin, visfatin, glucose and lipids were measured in the fasting state. A total of 14 subjects with T1DM and 14 controls volunteered to participate in a second phase of the study. They were studied on two occasions (phases A and B) with a time interval of about 1 week in between and in random order. In both phases an OGTT was performed. In phase A, before the OGTT 7 units of insulin lispro (approximately 1 unit for every 10 g of glucose consumed) was administered subcutaneously in the patients with T1DM, while an equal volume of water for injection (placebo) was administered in the control group. In phase B, no insulin or placebo was administered in either patients with T1DM or controls. Plasma levels of glucose, insulin, apelin and visfatin were measured at baseline, and 10, 20, 30, 60, 90, 120, 150, and 180 min after glucose consumption.
Results: Fasting plasma apelin concentrations were significantly higher in subjects with T1DM than in controls (1.93±0.14 vs. 1.39±0.09 ng/ml, p<0.001). On the contrary fasting visfatin levels were significantly lower in subjects with T1DM than in controls (17.55±1.68 vs. 25.28±3.63 ng/ml, p<0.001). Plasma apelin and visfatin levels did not change significantly during phase A of the experiment in either the group of patients with T1DM or the controls and there was no significant difference between the two groups. The same was valid for the phase B of the study. The overall apelin and visfatin response during the experiment, expressed as the area under the curve (AUC), was not significantly different between patients with T1DM and controls during either phase A or phase B of the study.
Conclusion: Apelin levels are higher and visfatin levels are lower in the fasting state in patients with T1DM in comparison with healthy controls. Additionally, they do not change during an OGTT with or without insulin administration.

Valsartan improves beta cell function and insulin sensitivity in normotensive subjects with impaired fasting glucose and/or impaired glucose tolerance

N.J. Van der Zijl[1], C.C.M. Moors[2], G.H. Goossens[2], M.H. Hermans[2], E.E. Blaak[2], M. Diamant[1];
[1]Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, [2]Human Biology, Maastricht University, Netherlands.

Background and aims: Recently, the NAVIGATOR trial, a long-term intervention study performed in normotensive subjects with impaired glucose metabolism (IGM), showed that treatment with the angiotensin-receptor blocker valsartan (VAL) for 5 years, resulted in a relative reduction of 14% in the incidence of T2DM. The underlying mechanisms are incompletely understood and may, besides improvement in insulin sensitivity also include a delay in beta-cell function decline.
Materials and methods: In the present study, we assessed the effect of 26-weeks VAL (320mg QD) vs. placebo (PLB) on various aspects of beta-cell function and insulin sensitivity in normotensive subjects with impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT). In this randomized, controlled, double-blind, two-center study, 43 IFG (51% males; mean±SE age 58±1.1 yrs; BMI 28.8±0.7 kg/m^2; BP 128/82±2/1 mmHg) and 36 IFG/IGT (53% males; age 58±1.1 yrs; BMI 29.5±0.7 kg/m^2; BP 131/82±2/1 mmHg) Caucasian subjects, received VAL (n=40) or PLB (n=39). Beta-cell function and insulin sensitivity were assessed at baseline and after 26 weeks treatment using a combined euglycaemic-hyperinsulinaemic and hyperglycaemic clamp with subsequent arginine-stimulation and a 2-hour 75-g oral glucose tolerance test (OGTT). Treatment effects were analyzed using ANCOVA, adjusting for center, glucometabolic status and gender.
Results: At week 26, VAL vs PLB, increased 1st-phase (P=0.06), and 2nd-phase glucose-stimulated insulin secretion (P=0.026). However, the enhanced arginine-stimulated insulin secretion did not differ (P=0.25). VAL vs PLB improved the disposition index (P=0.067) and insulin sensitivity (P=0.045). VAL but not PLB increased the OGTT derived insulinogenic index ((I_{30}-I_0)/(G_{30}-G_0), representing 1st-phase insulin secretion after an oral glucose load, P=0.035). At 26 weeks, VAL compared to PLB treatment resulted in a significantly greater reduction in systolic and diastolic blood pressure (P<0.001). BMI remained unchanged in both treatment groups.
Conclusion: Twenty-six week VAL treatment showed a significant improvement in glucose-stimulated insulin release and insulin sensitivity in normotensive subjects with IGM. These findings may partly unveil the mechanisms underlying the observed effects of VAL in the prevention or delay of the onset of T2DM.

Valsartan induced improvement of insulin sensitivity was not associated with improved microvascular function in subjects with impaired glucose metabolism

C.C.M. Moors[1], N.J. Van der Zijl[2], G.H. Goossens[1], R.G. IJzerman[3], E.E. Blaak[1], M. Diamant[3], E.H. Serné[3];
[1]Human Biology, Maastricht University, [2]Diabetes Centre, VU University Medical Centre, Amsterdam, [3]Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Microvascular dysfunction, affecting both flow resistance and perfusion, is not only important in the development of target-organ damage in the heart, kidney and eyes, but also in the development of insulin resistance. Capillary recruitment is an important mechanism by which insulin promotes uptake of glucose. Capillary rarefaction and impaired recruitment may therefore reduce glucose uptake and contribute to insulin resistance. Recently, in the NAVIGATOR trial, a long-term intervention study performed in normotensive subjects with impaired glucose metabolism (IGM), a relative risk reduction of 14% in the incidence of T2DM was reached with the angiotensin-receptor blocker valsartan (VAL). The underlying mechanisms are incompletely understood but may include enhanced peripheral insulin sensitivity and beneficial effects on microvascular function. In this study we investigated the relation between functional and structural capillary density and insulin sensitivity in subjects with impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT). Furthermore, we examined whether 26-weeks of VAL treatment improved insulin sensitivity and microvascular function.
Materials and methods: Caucasian subjects with IFG (n=29, 52% males; mean±SE age 57±1.4 yrs; BMI 29±1.1 kg/m^2; BP 130/81±3/1 mmHg) and combined IFG/IGT (n=19, 63% males; mean±SE age 56±1.4 yrs; BMI 30±1.2 kg/m^2; BP 131/84±3/2 mmHg), were treated with VAL for 26 weeks. Glucose tolerance was assessed with a 2-hour oral glucose tolerance test (OGTT). At baseline and after 26-weeks subjects underwent a) an euglycaemic-hyperinsulinaemic clamp to assess insulin sensitivity and b) capillaroscopy to examine functional skin capillary density at baseline and after 4 minutes of arterial occlusion as well as structural capillary density during venous occlusion. 16 normoglycaemic healthy subjects (NGT, 62% males; mean±SE age 54±1.8 yrs; BMI 28±0.7 kg/m^2; BP 122/78±2/2 mmHg) were the control group.
Results: Subjects with IFG and combined IFG/IGT were more insulin resistant compared to NGT (M-value: 4.8 ±2.3 mg/min/kg, 4.6 ±1.2 mg/min/kg and 9.4 ±3.0 mg/min/kg, P<0.001, IFG/IGT, IFG and NGT, respectively). In subjects with IFG, IFG/IGT, capillary density was reduced in the basal state, during venous occlusion and after arterial occlusion compared to controls (all P<0.001). Functional and structural capillary density was positively correlated with insulin sensitivity (all P=0.004). In multivariable regression analyses, the associations between capillary density and insulin sensitivity were independent of age, sex, blood pressure and BMI (P=0.04). 26-weeks of VAL treatment improved insulin sensitivity (P=0.038), without changes in microvascular function.
Conclusion: Subjects with IFG and IFG/IGT are characterized by impaired functional and structural capillary density. The microvascular dysfunction was associated with diminished insulin sensitivity. Treatment with VAL did improve insulin sensitivity, however there were no changes in microvascular function.

Effect of the interleukin-1 receptor antagonist anakinra on insulin sensitivity in obese, insulin resistant individuals: results from a double-blind placebo-controlled study

E.J.P. van Asseldonk, R. Stienstra, T.B. Koenen, M.G. Netea, C.J. Tack;
General Internal Medicine, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: The global prevalence of obesity is rapidly rising and paralleled by an increasing incidence of type 2 diabetes mellitus. Strong evidence has emerged that inflammatory changes link excess energy/fat to insulin resistance, one of the prime pathophysiological defects in type 2 diabetes. In vivo studies in mice and in vitro experiments have demonstrated that obesity activates Interleukin (IL)-1, which subsequently leads to insulin resistance. Blocking IL-1 by recombinant IL-1Receptor antagonist (Ra) thus should diminish insulin resistance. Recent findings show that blocking IL-1 by recombinant human IL-1Ra, anakinra, improves glycemic control in patients with type 2 diabetes. In the present study we investigated whether anakinra was able to improve insulin sensitivity in obese, insulin resistant but non-diabetic subjects.
Materials and methods: Non-diabetic subjects were treated with anakinra 150 mg s.c. once daily or matching placebo for 4 weeks in a double blind cross-over study. Between treatment periods there was a 4 weeks wash-out interval. Inclusion criteria: age ≥18 yrs, BMI ≥ 30 kg/m^2 and ≥ 3 characteristics of the metabolic syndrome (IDF definition). 19 Patients were included in the study and randomized. Power calculations revealed that 12 paired observations would provide sufficient power to detect a 20% difference in insulin sensitivity.Insulin sensitivity (primary endpoint) was evaluated using a euglycemic hyperinsulinemic clamp, beta-cell functions by oral glucose tolerance test (OGTT). After each treatment period, a subcutaneous fat biopsy was taken to evaluate effects at the level of the fat tissue.
Results: A total of 13 subjects (F:M = 9:4) completed all studies, 6 withdrew from the study. Most subjects experienced local injection site reactions. Average BMI at baseline was 33 ± 5 kg/m^2 and this did not change during the study. Anakinra had no effect on insulin sensitivity (glucose disposal rate 19.8 ± 2.3 for anakinra vs 18.6 ± 2.5 µMol/kg/min for placebo P=0.44, nor on insulin sensitivity index 0.17 ± 0.03 vs 0.14 ± 0.02 µMol/kg/min/mE P=0.15). HbA1c, fasting glucose levels and C-Peptide during OGTT were not affected. The disposition index improved significantly after anakinra treatment (154 ± 26 vs,106 ± 20 pmol/mmol P=0.04). Markers of systemic inflammation HsCRP, IL-6 and IL-8 remained unchanged. IL-1Ra levels in serum and in fat were significantly higher during treatment with anakinra (serum 735 ± 86 vs 0.66 ± 0.09 µg/l P<0.001, fat 217 ± 19 vs 47.7 ± 9.0 ng/mg fat tissue $P<0.001$).
Histochemical analysis of fatbiopsies showed higher numbers of CD68-positive cells, while expression of PPARγ, and FABP4 significantly decreased in adipose tissue after anakinra treatment (both P<0.05), adiponectin tended to decrease (P=0.07).No carry-over effects were found.
Conclusion: Treatment with anakinra does not result in improved insulin sensitivity in obese, insulin-resistant, non-diabetic subjects. While there was a hint towards an improved insulin secretion, no beneficial changes were found at the fat tissue level. Either the dose of anakinra is too low, the half life too short, or IL-1 plays a relatively minor role at the level of the human fat tissue.

Long-term effect of anti TNF-alpha therapy on insulin resistance, body composition and adipokines

M.-T. Arce-Franco[1], I. Ferraz-Amaro[2], V. Hernandez-Hernandez[2], M.-J. Domínguez-Luis[2], J.G. Oliva-Garcia[3], A.M. Herrera[2], J.R. Muñiz[4], F. Diaz-Gonzalez[2], J. Lopez-Fernandez[1];
[1]Endocrinology Department, Hospital Universitario de Canarias (HUC), [2]Rheumatology Department, HUC, [3]Endocrinlogy and Nutrition Department, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain, [4]IMETISA, HUC, La Laguna, Spain.

Background and aims: Insulin resistance (IR) is a condition associated, among others to abdominal obesity, endothelial dysfunction, hypertension, atherogenic lipid profile, type2 diabetes mellitus and cardiovascular (CV) events. Remarkably, IR has been observed in inflammatory chronic diseases, like rheumatoid arthritis (RA), which suggests that IR and systemic inflammatory response are linked events. It has been suggested that tumour necrosis factor(TNF)-α, a proinflammatory cytokine that plays a key role in the pathogenesis of several human inflammatory disease, might be a connection between inflammation and CV disease apparently through its effects on endothelial function, vascular homoeostasis, IR, as well as on production of adipokines. However, the clinical significance of this potential association has not been fully confirmed. The aim of this study was to determine whether or not chronic blockade of systemic TNF-α in humans has some influence on CV-associated risk factors, such as insulin sensitivity, body fat distribution, body composition, physical activity or levels of adipokines.
Material and methods: Sixteen patients with RA (mean age 50.8±14.6 years, mean duration of disease 6.3±2.7 years) in whom anti-TNFα agents were added to methotrexate because active disease were followed up during a year. At baseline and after 3 and 12 months of TNFα treatment, we assessed: disease activity by DAS28, physical activity by accelerometry, anthropometric measures, IR by Homeostatic Model Assessment (HOMA-2), body composition by multifrequency bioelectric impedance analysis, abdominal fat dis-

tribution (subcutaneous and intraabdominal) by magnetic resonance (MR) imaging and serum level of several key adipokines by ELISA. None patient used steroids a month before the start or during the study.
Results: In spite of a significant improvement in DAS28, patients' physical activity remains stable during the follow up. The body mass index showed a significant increase after one year (25.7±3.2 vs 28.06±4.5 kg/m2, p=0.02) of treatment with anti-TNFα. The body composition (impedance) in terms of fat and fat-free mass showed no difference between visits except for a significant elevation of body cell mass (25.5±4.6 vs 26.6±3.1 kg, p=0.02). Values of visceral intraabdominal and subcutaneous abdominal adipose tissue by MR were not modified because of treatment. HOMA-2 values showed not changes in β-cell function or IR index but a significant increase (110[94-138] vs 118[107-156]%, p=0.045) in insulin sensitivity after 3 months was observed. Basal levels of adiponectin, visfatin, leptin, ghrelin, resistin, and apelin did not change in response to anti-TNF-α treatment; only retinol binding protein 4 showed a significant change (51.7±32.7 vs 64.9±28.4 μg/mL, p=0.03) at the end of the study.
Conclusions: IR, adiposity, body composition and adipokines are not significantly affected by 1 year blockade of TNFα in RA patients. More studies with longer period of follow-up must be done to further clarify the real beneficial role of chronic anti-TNFα treatments in cardiovascular risk factors.

In type 2 diabetic patients the improvement in insulin sensitivity is associated with a decrease in plasma C-peptide levels and an improvement in intima media thickness
C. Hohberg[1], A. Pfützner[1], I. Kleine[2], M. Löbig[1], W. Fuchs[2], T. Forst[1];
[1]Institute for Clinical Research and Development, Mainz, Germany, [2]Takeda Pharma, Aachen, Germany.

Background and aims: There is increasing evidence that in type 2 diabetic patients increased C-Peptide levels might predict vascular inflammation and the progression atherosclerotic plaques. The aim of this study was to investigate a potential relationship between the decrease in plasma C-peptide levels and an improvement in intima media thickness (IMT) during treatment with Pioglitazone.
Materials and methods: The Pioneer Study investigated the change in IMT over 6 months in 89 type 2 diabetic patients treated with pioglitazone (PIO: age 62.2±8.4 years; duration of diabetes 89.8 months) and in 84 type 2 diabetic patients treated with glimepiride (GLIM: age: 63.0±7.4 years; duration of diabetes 82.5±77.5 months). At baseline and after 6 months the IMT was measured at the common carotid artery and fasting blood samples were taken for the measurement of glucose, insulin, C-peptide, and HbA1c. The $HOMA_{IR}$ Score was calculated as a measure of insulin resistance.
Results: Both treatments resulted in a comparable improvement in HbA1c levels (PIO: from 7.52±0.85 to 6.71±0.89; GLIM: from 7.44±0.89 to 6.83±0.85 %, p<0.05). During treatment with pioglitazone the IMT declined from 0.949±0.149 to 0.893±0.144 mm (p<0.05), while no significant change in IMT could be observed in the GLIM group (from 0.924±0.150 auf 0.911± 0.158 mm (n.s.). Pioglitazone treatment declined the $HOMA_{IR}$ Score from 6.2±4.1 to 3.9±1.9(p<0.05), and C-peptide levels from 2.03±0.94 to 1.69±0.75 ng/ml (p<0.05) . During GLIM treatment, $HOMA_{IR}$ changed from 5.8±3.7 to 6.0±4.7 (n.s.), and C-peptide changed from 1.95±0-85 to 1.94±0.96 ng/ml; (n.s.). A linear correlation could be observed in between the decrease in IMT and the $HOMA_{IR}$ Score (r=0.29; p<0.05), and a decrease in plasma C-peptide (r=0.28; p<0-05).
Conclusion: This study confirmed a linear association between the decrease in IMT and an improvement in insulin sensitivity, as well as a decline in plasma C-peptide levels. The study further emphasizes the complex interrelationship in between Insulin and C-peptide secretion and vascular pathology in patients with diabetes mellitus type 2.

Long-term treatment with the angiotensin-receptor blocker valsartan improves adipose tissue function in normotensive subjects with impaired glucose metabolism
G.H. Goossens[1], C.C.M. Moors[1], N.J. van der Zijl[2], J.P. Cleutjens[3], M. Diamant[2], E.E. Blaak[1];
[1]Department of Human Biology, NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre, [2]Department of Internal Medicine, VU University Medical Centre, Amsterdam, [3]Department of Pathology, Cardiovascular Research Institute Maastricht, Maastricht University Medical Centre, Netherlands.

Background and aims: Adipose tissue dysfunction may contribute to the development of obesity-related insulin resistance and type 2 diabetes (T2D). Increased activity of the renin-angiotensin system in obese insulin resistant subjects may be implicated. The recently published prospective NAVIGATOR trial demonstrated that the angiotensin-receptor blocker valsartan (VAL), at median follow-up 5.0 years, reduced the incidence of T2D by 14% compared to placebo (PLB) in normotensive subjects with impaired glucose metabolism (IGM). However, no underlying mechanisms were reported. We hypothesized that VAL treatment in subjects with IGM improves adipose tissue function, which in turn may contribute to increased insulin sensitivity.
Materials and methods: In this randomized, placebo-controlled, double-blind, two-center study, the effect of VAL (320 mg daily) or PLB on insulin sensitivity (hyperinsulinaemic-euglycaemic clamp) was investigated before and at 26 weeks of therapy in 79 normotensive subjects with impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT) (52M/48F; age 58±7 yrs; BMI 29.7±4.3 kg/m^2; BP 130/82±11/6 mmHg). In a subgroup of 17 IFG (10M/7F; age 60±1 yrs; BMI 29.5±0.9kg/m^2; BP 127/78±2/3 mmHg) and 14 IFG/IGT (6M/8F; age 59±1 yrs; BMI 32.1±1.2kg/m^2; BP 129/82±2/2 mmHg) subjects matched for age, BMI and blood pressure, the effects of VAL or PLB on adipose tissue function was examined. Adipose tissue blood flow (ATBF) was measured under fasting conditions and for 4h after intake of a high-fat mixed-meal using the ^{133}Xe wash-out technique. In addition, abdominal subcutaneous adipose tissue biopsies were obtained for measurement of mean adipocyte diameter and size distribution. In addition to treatment effects, baseline comparisons were made between men and women and between subjects with different glucometabolic status (mixed ANOVA).
Results: At baseline, fasting ATBF was lower (P=0.01) and mean abdominal adipocyte size higher (increase in fraction of large adipocytes and decrease in small adipocytes, P<0.01 for both) in women (7IFG / 8IFG/IGT) compared to men (10IFG / 6IFG/IGT). No significant differences were found for baseline ATBF and adipocyte size between IFG and IFG/IGT subjects. VAL increased insulin sensitivity (P=0.045), fasting ATBF (P=0.02) and postprandial $ATBF_{AUC\ 0\text{-}4h}$ (P=0.04) compared to PLB. In addition, mean adipocyte diameter was decreased by VAL compared to PLB (P<0.001), with a shift towards a higher proportion of small and less large adipocytes (P<0.001 for both), whereas no changes in body weight were noted.
Conclusion: 26-weeks VAL treatment increased insulin sensitivity, fasting and postprandial ATBF and decreased mean abdominal subcutaneous adipocyte size, with a shift from large to small adipocytes, in subjects with IGM. The present data suggest that improved adipose tissue function may contribute to the reduced development of T2D in patients following long-term VAL treatment.

The relationship of serum A-FABP, retinol binding protein 4, and adiponectin levels to the development of metabolic syndrome in children: a 3-year prospective cohort study

S.J. Yang, M.J. Cho, H.Y. Choi, Y.J. Kim, J.H. Kim, C.R. Eun, H.J. Yoo, H.Y. Kim, J.A. Seo, N.H. Kim, S.G. Kim, S.H. Baik, D.S. Choi, K.M. Choi; Endocrinology and Metabolism, Korea University College of Medicine, Seoul, Republic of Korea.

Background and aims: Adipocyte-fatty acid binding protein (A-FABP) and retinol binding protein 4 (RBP4) has been reported to be associated with metabolic syndrome in adults. We evaluated the prospective association of A-FABP, RBP4, and adiponectin with metabolic syndrome as defined by pediatric adaption of the National Cholesterol Education Program criteria.
Materials and methods: In this prospective cohort study, 159 boys from the school-based Metabolic disorders & Obesity Study in Elementary School children (MOSES) study were followed up for 3 years.
Results: At baseline, A-FABP levels (12.8 ± 5.1 μg/L vs. 23.6 ± 8.2 μg/L, *P* <0.001) and RBP4 levels (59.7 ± 15.3 vs. 69.3 ± 17.1, *P* = 0.001) were significantly higher, whereas adiponectin levels (18.1 ± 8.4 μg/mL vs. 11.5 ± 5.4 μg/mL, *P* <0.001) were significantly lower in overweight children compared to normal control. During 3 year of follow-up, in addition to their association with change of weight, A-FABP levels were positively associated with change of waist circumference and adiponectin levels were negatively associated with change of triglyceride. Although both baseline A-FABP and adiponectin were associated with the development of metabolic syndrome, multiple logistic regression analysis showed that only A-FABP was the independent predictor of the development of metabolic syndrome after adjustment for Tanner stage, insulin resistance, and BMI during 3 year of follow-up (odds ratio, 12.0; 95% CI, 1.3 to 107.4; highest versus lowest tertile).
Conclusion: A-FABP predicts the development of metabolic syndrome independently of adiposity and insulin resistance in Korean boys.

Table 1. Logistic regression analysis of baseline adipokines in the prediction of the development of metabolic syndrome at 3 years later.

		Q1	Q2	Q3

The relationship between liver fat content and insulin resistance and beta cell function in individuals with different status of glucose metabolism

H. Bian[1], H. Lin[1], S. Rao[2], X. Yao[2], M. Zeng[2], J. Zhou[3], W. Jia[3], X. Gao[1];
[1]Department of Endocrinology and Metabolism, Zhongshan Hospital, Fudan University, [2]Department of Radiology, Zhong Shan Hospital, Fudan University, [3]Department of Endocrinology and Metabolism, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.

Aims: Nonalcoholic fatty liver disease (NAFLD) is commonly associated with type 2 diabetes, dyslipidemia, and insulin resistance. Many studies have shown NAFLD was a predictor of type 2 diabetes and metabolic syndrome. Excess deposition of liver fat may be affect the glucose by deteriorating the β-cell function and increasing the insulin resistance. This study aims to study the relationship between liver fat content(LFC), insulin resistance and β-cell function in individuals with different status of glucose metabolism in China.
Materials and methods: 109 subjects including 31 impaired glucose regulation (IGR), 31 newly diagnosed type 2 diabetes (NT2DM) and 47 normal control(NC) with normal metabolic parameters were involved in the study by measuring the LFC using Proton magnetic resonance spectroscopy, evaluating the insulin resistance and β-cell function using C peptide and insulin from oral 75g glucose tolerance test.
Results: (1)LFC was 3.83%, (inter-quartile range, 2.35-7.59%),12.82%(inter-quartile range, 8.10-21.37%),21.99%(inter-quartile range, 11.89-34.43%) in NC,IGR,NT2DM groups and was elevated in turn(*P*<0.01);(2) The subjects were divided into four subgroups by LFC Quartile named Quartile 1-4 associated with the increasing LFC.HOMA-IR were elevated from Quartile 2 by turns(*P*<0.01);(3) Insulin from 0 to 30 min (ΔI_{30}),the ratio of change in insulin from 0 to 30 min to that in glucose from 0 to 30 min ($\Delta I_{30}/\Delta BG_{30}$),and C peptide from 0 to 30 min (ΔCP_{30}) increased in Quartile 2,then decrease in Quartile 3,but without statistical significance. In Quartile 4 ,$\Delta I_{30}/\Delta BG_{30}$ and ΔCP_{30} sharply decreased(*P*<0.05,and *P*<0.01). The ratio of C peptide from 0 to 30 min to that in glucose from 0 to 30 min ($\Delta CP_{30}/\Delta BG_{30}$) begun to decrease from Quartile 3(*P*<0.05). The ratio of area under curve of C peptide to area under curve of glucose (CP_{AUC} / BG_{AUC}) were significantly decreased from Quartile 3(*P*<0.05). From Quartile 3,glucose level abnormally elevated to the diagnosis value of IGR(*P*<0.01)(Tab 1);(4) LFC was positively correlated with HOMA-IR(r_s =0.618)(*P* <0.01),but was negatively correlated with ΔCP_{30}(r_s=-0.282),$\Delta CP_{30}/\Delta BG_{30}$($r_s$=-0.404),$CP_{AUC}$ / BG_{AUC}(r_s=-0.308)(All *P* <0.01);(5)Stepwise regression analysis demonstrated LFC was the strongest predictor of HOMA-IR .But LFC failed to enter all models about β-cell function.
Conclusion: LFC was an independent risk factor of insulin resistance. When LFC moderate increased, the early phase of insulin secretion also compensatively increased, but as the LFC further deposition, both the early phase and whole β-cell function were deteriorated, and hyperglycemia developed. These suggest that deposition of LFC participates in the pathogenesis of type 2 diabetes.

Defects in glutaeal adipogenesis are associated with obesity-related insulin resistance in black South African women

J.H. Goedecke[1,2], K. Adams[3], P. Hayes[3], J. Evans[2], J. Dave[3], N.S. Levitt[3], E.V. Lambert[2], S.E. Kahn[4], T. Olsson[5];
[1]South African Medical Research Council, Cape Town, South Africa, [2]Department of Human Biology, University of Cape Town, South Africa, [3]Department of Medicine, University of Cape Town, South Africa, [4]Division of Metabolism, Endocrinology, and Nutrition, Department of Medicine, VA Puget Sound Health Care System and University of Washington, Seattle, USA, [5]Department of Medicine, Umeå University, Sweden.

Background and aims: It has been proposed that defects in the ability to store fat in subcutaneous adipose tissue (SAT) depots may be associated with increased visceral adipose tissue (VAT) accumulation and decreased insulin sensitivity (S_I). The aims of the study were to measure the expression of genes involved in adipogenesis in abdominal SAT and gluteal depots, and determined their relationship with VAT and S_I in black and white South African women who differed in body fat distribution and S_I.
Materials and methods: VAT (computerised tomography scan), S_I (frequently sampled intravenous glucose tolerance test), and abdominal and gluteal SAT gene expression were measured in 14 normal-weight (BMI <25 kg/m^2) black, 14 normal-weight white, 15 obese (BMI >30 kg/m^2) black and 13 obese white South African women.
Results: With increasing BMI, black women accumulated less VAT (P=0.03) and more abdominal SAT (P=0.017), but had lower S_I (P<0.01) than white women. After adjusting for differences in VAT and S_I, abdominal SAT adipogenic gene expression did not differ by ethnicity. However, gluteal SAT expression of adipogenic transcription factors (CEBPβ and STAT5a) were

higher in black than white women (P<0.05). In contrast, gluteal expression of adipogenic (PPARγ), lipogenic (FASN, PEPCK) and lipolytic (HSL, FABP) genes were down-regulated in obese black women (P<0.05). Further, CEBPα (r=0.53, P=0.007), FASN (r=0.50, P=0.011), PEPCK (r=0.45, P=0.024), LPL (0.52, P=0.008), HSL (r=0.59, P=0.002) and FABP (r=0.61, P=0.001) mRNA levels in gluteal SAT, but not abdominal SAT, correlated with S_I in black women, independent of % body fat. In white women, FASN expression in both gluteal and superficial SAT depots correlated equally with S_I (r=0.47, P=0.025). VAT correlated negatively with mRNA levels of adipogenic transcription factors (CEBPα (r=-0.47, P=0.025), CEBPβ (r=-0.44, P=0.037) and SREBPS (r=-0.46, P=0.028)) in white women, whereas in black women, no associations with VAT were found.
Conclusion: Obese black women have impaired expression of gluteal SAT adipogenic genes compared to white women, which associates with reduced S_I. These findings therefore refute the hypothesis that black South African women display 'healthy obesity' due to their greater peripheral fat distribution, but rather suggests that obesity in black women impairs gluteal SAT adipogenesis and storage, potentially leading to insulin resistance, which increases the risk for type 2 diabetes.

Adipose tissue dysregulation and reduced insulin sensitivity in non-obese individuals with enlarged abdominal adipose cells
A. Hammarstedt, U. Smith;
Molecular and Clinical Medicine, Medicine, Goteborg, Sweden.

Background and aims: Obesity promotes type 2 diabetes through induction of insulin resistance. Insulin resistance in the adipose tissue is, however, seen long before type 2 diabetes develops and this is associated with a dysfunctional adipose tissue including an impaired ability to recruit pre-adipocytes and, thus, promoting adipocyte hypertrophy. Animal studies have shown that expansion of the adipose tissue does not necessarily affect the metabolic phenotype as long as the adipose tissue is not dysfunctional. In order to examine this in man, we here investigated GLUT4 expression and other markers of insulin resistance in the adipose tissue, including adipose cell size as a marker of impaired pre-adipocyte differentiation in non-obese, first-degree relatives to type 2 diabetic patients in relation to the whole-body phenotype.
Materials and methods: 34 non-obese, first-degree relatives to type 2 diabetic patients were recruited through advertisement in a local newspaper. Anthropometric measures were recorded, blood samples collected for quantification of circulating factors and insulin sensitivity measured by the hyperinsulinaemic-euglycaemic clamp method. Abdominal subcutaneous adipose tissue biopsies were obtained, adipocyte cell size and gene and protein expression were measured.
Results: Our findings show that these individuals, although non-obese, exhibit clear signs of a dysfunctional adipose tissue, characterized by low expression of GLUT4, altered adipokine profile, and enlarged adipocyte cell size that correlate with the clinical phenotype and insulin sensitivity. In summary, cell size, in these non-obese individuals, is correlated with WHR (R=0.42, p=0.014), f-glucose (R=0.30, p=0.085), fs-insulin (R=0.58, p<0.001), HbA1c (R=0.33, p=0.058), GIR (R=-0.41, p=0.016), TG (R=0.44, p=0.009), s-HDL cholesterol (R=-0.41, p=0.017), s-Adiponectin (R=-0.56, p=0.001), GLUT4 mRNA (R=-0.45, p=0.007) and GLUT4 protein (R=-0.29, p=0.095). In addition, GLUT4 expression in the adipose tissue and circulating adiponectin, which is secreted from the adipose tissue, was closely related (mRNA: R=0.42, p=0.013; protein: R=0.36, p=0.037) and show a similar association with clinical parameters.
Conclusion: In conclusion, these findings support the concept that it is not obesity per se, but rather the presence of a dysregulated adipose tissue which relates to whole-body insulin sensitivity and the associated phenotype.

Retinol binding protein-4, insulin sensitivity and intima media thickness in non diabetic subjects with normal glucose tolerance
E. Muscelli, A. Solini, C. Morizzo, B.D. Astiarraga, C. Palombo, A. Casolaro, M. Kozakova;
Department of Internal Medicine, University of Pisa, Italy.

Background and aims: Retinol binding protein-4 (RBP4) is a novel adipokine able to modulate the action of insulin in several tissues; its role in humans is controversial. RBP4 has been associated to increase in carotid intima-media thickness (IMT) in hypertensive women but its association with early atherosclerotic changes in normortensive subjects was not studied. Thus, the aim of the present study was to evaluate the relationship between RBP4 and insulin sensitivity and IMT in lean and obese non-diabetic normotensive subjects.
Materials and methods: Insulin sensitivity (euglycemic hyperinsulinemic clamp), IMT in common carotid artery (high-resolution B-mode ultrasound) and serum RBP4 levels were assessed in 72 subjects (39 males, 43.9 ± 8.3 years; BMI 27.1 ± 4.6 kg/m2 [range 19.1 to 30.3 kg/m2]). Study subjects were divided in lean (L, n=29), overweight (OW, n=17) and obese (OB, n=26).
Results: Insulin sensitivity (M value) ranged from 11.9 to 81.2 μmol/kg FFM/min (mean±SD = 50.0±14.0 μmol/kg FFM/min) and was lower in OB (L = 60.0±12.7; OW = 45.7±11.1 and OB = 42.3±12.4μmol/kg FFM/min, p<0.0001). IMT was higher in OB and OW, as compared to L (OW = 0.601 ± 0.081 and OB = 0.658 ± 0.092mm vs. L = 0.589 ± 0.074, p=0.01). RBP4 levels were similar between genders, BMI subgroups and between the lowest and higher M quartile (56.2 ± 32 vs. 55.8 ± 28.3 μg/ml; p=ns). In the whole study no relationship was observed between RBP4 and BMI, blood pressure, M value, IMT, plasma adiponectin and glucose and insulin plasma levels during the OGTT. IMT was independently correlated only with age and weight (r2=0.35; p<0.0001).
Conclusion: In non-diabetic normotensive subjects, RBP4 levels are neither related to the degree of obesity and of insulin sensitivity nor to blood pressure and to IMT. In this healthy population increase in IMT seems to reflect physiologic aging and adaptation to body size.

Nonalcoholic steatohepatitis (NASH) is a prediabetic state frequently associated with abnormal glucose tolerance and severe hepatic and adipose tissue insulin resistance
K. Cusi, B. Orsak, C. Ortiz-Lopez, R. Lomonaco, J. Hardies, V. Kochunov, C. Darland, J. Finch;
UTHSCSA, San Antonio, USA.

Background and aims: No previous study has systematically screened patients with nonalcoholic steatohepatitis (NASH) for type 2 diabetes mellitus (T2DM). In addition, the role of hyperglycemia and insulin resistance (IR) in relation to the severity of NASH is poorly understood. To better understand this, we studied the prevalence of impaired fasting glucose (IFG), IGT and T2DM, and the impact of glucose tolerance status and IR on liver histology, in biopsy-proven NASH pts from the University of Texas at San Antonio NASH Trial (NCT00994682). This large (n=120) study aims to understand the metabolic/molecular mechanisms associated with NASH and the efficacy/safety of long-term treatment with pioglitazone.
Materials and methods: We report on 79 subjects. Clinical characteristics: age=51±1, gender=52/27 (M/F), BMI=35.8±0.9 kg/m2, FPG=123±4 mg/dl, A1c=6.4±0.2%, AST=48±3/ALT=73±3 IU/L). We measured: 1) glucose, insulin and FFA during an OGTT; 2) liver fat by magnetic resonance spectroscopy (MRS); 3)]liver/muscle (Rd) insulin sensitivity (euglycemic insulin clamp with 3H glucose and indirect calorimetry); and 4) hepatic (Hep-IR index= EGP x fasting plasma insulin [FPI]) and adipose tissue (Adipo-IR index= fasting FFA x FPI) insulin resistance. Liver histology was assessed by Kleiner criteria.
Results: In a predominantly Hispanic population (~2/3) glucose metabolism was abnormal in 90% of patients with 51% of these being unaware of this until testing. In those not known previously to have diabetes, 22% were newly diagnosed T2DM, 40% had both IFG and IGT, 20% IFG or IGT while only 18% had normal fasting/postprandial glucose metabolism. While T2DM and non-diabetics with NASH were well matched for age, ethnicity, percent body fat (DXA), lipids and liver steatosis (both by MRS [27±3%] and histology), T2DM patients had worse steatohepatitis (data available in 69) (necroinflammation= 2.8±0.1 vs. 1.8±0.1) and ALT (83±9 vs. 64±5 IU/L, both p<0.001). Diabetics were more insulin-resistant at the level of the liver (Hep-IR=36.1±9.0 vs. 23.9±4.6 mg/kg−1•min−1•μU/ml; suppression of EGP by low-dose insulin infusion: -59% vs. 83%, both p<0.001) and adipose tissue (Adipo-IR= 13.3±1.8 vs. 8.5±1.1 mmol/liter•U/ml, p<0.001). In contrast, Rd (muscle) was diminished but identical in both groups (2.3±0.4 mg/kg−1•min−1). Hepatocyte necroinflammation correlated closely with A1c, Hep-IR and Adipo-IR (p<0.05-0.01).
Conclusion: The prevalence of IFG, IGT and T2DM in a predominantly Hispanic population with NASH is much higher than previously appreciated and such patients may benefit from early screening for T2DM. Patients with NASH and T2DM have worse steatohepatitis, which appears related at least in part, to their more severe hepatic and adipose tissue insulin resistance.

Insulin resistance, rather than BMI, predicts metabolic severity in anorexia nervosa

A. Prioletta, G. Muscogiuri, C. Cipolla, E. Salomone, G. Sorice, T. Mezza, S. Della Casa, A. Giaccari;
Endocrinology, Catholic University, Rome, Italy.

Introduction: Anorexia nervosa (AN) is a psychiatric eating disorder, characterized by self-induced weight loss and body image distortion. The prolonged starvation causes changes in body composition as loss of fat and lean masses while nutritional recovery results in significant changes in body composition, especially in fat mass distribution as well as in FT3 normalization. It is well known that changes in body composition may modify insulin-sensitivity (IS) nevertheless, the determination of insulin sensitivity in AN has provided conflicting results.
Aim: In our study we aimed to examine IS, measured by hyperinsulinemic euglycemic clamp (HEC), in patients affected by AN. The second aim was to evaluate the relationship between IS and the usual clinical parameters of recovery from AN, including FT3 and body fat mass.
Subjects and methods: 26 women with restrictive AN (age 24.4± 6.0 years; disease duration 66.4±7.8 months), were enrolled. We measured BMI, hormones (FT3, FT4, TSH, serum and urinary free cortisol, GH and IGF-1), and performed OGTT and HEC. Body composition was determined by dual energy X-ray absorptiometry (DEXA). Fat body mass was calculated for the total body and for trunk and leg regions. We considered patients in partial recovery if FT3 was within normal range (≥ 2 pg/ml).
Results: All studied subjects were normo-tolerant. After dividing the cohort based on FT3 levels, the two groups were similar in age and disease duration although subjects with normal FT3 levels had higher BMI, total fat mass, trunk fat mass and ratio trunk fat mass/total fat mass ($p<0.05$). No differences in the levels of plasma and urinary cortisol, GH, TSH, FT4 were present. The group with low FT3 had lower IGF1 ($p<0.05$). A linear negative correlation was observed between glucose uptake during HEC and trunk fat mass (R=-0.72; p=0.01), while no correlation between glucose uptake and BMI (R=-0.08; p=0.82) was found. A linear negative correlation was shown between FT3 and glucose uptake (R=-0.75; p=0.01); and (positive) with abdominal fat (R=0.901; p=0.003).
Discussion: The inverse correlation found between body fat mass (trunk and total) and glucose uptake and the absence of any correlation between BMI and glucose uptake allow us to hypothesize that, in patients with anorexia nervosa, BMI is not a reliable index of metabolic status, in opposite to what was observed in patients with metabolic syndrome or diabetes. The measurement of body fat by DEXA seems to be more reliable than BMI. Our study also showed that the metabolic alterations and the body composition were correlated with indices of disease that per se could constitute a marker of the metabolic state in these patients, offering a reliable prognostic indications. In perspective, although AN patients in partial recovery were still with an extremely reduced fat mass, we hypothesize that the reappearance of fat exclusively in the abdomen induces insulin resistance and may contribute to the usual difficulty to reach normal weight in these patients.

608

Does insulin resistance or insulin secretion predict weight changes in non-diabetic subjects?

E. Rebelou, E. Muscelli, M. Nannipieri, S. Camastra, E. Ferrannini, on behalf of the RISC Study investigators;
Department of Internal Medicine, University of Pisa, Italy.

Background and aims: Previous studies using the euglycaemic insulin clamp technique have reported that a high degree of insulin sensitivity predicts weight gain. This association, however, has not been confirmed in other studies using different surrogate measures of insulin sensitivity. Likewise, both increased and decreased insulin secretion have been linked with weight gain. We therefore undertook to systematically analyse the relationship between insulin sensitivity/secretion and spontaneous weight changes in non-diabetic subjects.
Materials and methods: In 1,048 subjects from the RISC cohort (561 women and 467 men, mean age 44 years) followed up for 3 years, we measured baseline insulin sensitivity (by a 240 pmol.min.m-2 insulin clamp) and ß-cell function (i.e., fasting insulin secretion rate, total insulin output and ß-cell glucose sensitivity, by mathematical modelling of the C-peptide response to oral glucose).
Results: In the whole cohort, both men and women gained weight over 3 years (0.9 [4.6] and 0.9 [4.6] kg, respectively, median [IQR], $p<0.0001$ vs zero). Baseline BMI was significantly higher in both weight gainers (top 20% of the distribution of BMI changes, +6 [3] kg) and weight losers (bottom 20%, -4 [3] kg) as compared to weight stable subjects (25.7 [5.0] and 26.3 [4.6] kg.m-2 , respectively, vs 24.3 [4.6] kg.m-2, $p<0.0001$ for both). In contrast, insulin sensitivity (as the M or M/I index) was not associated with either weight gain or weight loss across quartiles of baseline BMI. By multiple logistic or linear regression analyses adjusting for centre, age and sex, baseline waist circumference (or BMI or body weight) was the only significant, independent predictor of both weight gain and weight loss. In none of these models did any parameter of ß-cell function show an independent association with weight changes; this was also the case for baseline glucose tolerance status (NGT, IFG or IGT).
Conclusion: In a large cohort of non-diabetic Caucasian subjects, neither insulin sensitivity nor insulin secretion predicts spontaneous weight changes. As compared to lean subjects, heavier individuals are prone to either gaining or losing weight regardless of their degree of insulin sensitivity.

A multi-marker risk score predicts insulin sensitivity and beta cell function-driven type 2 diabetes from a fasted sample

S.M. Watkins[1], M.W. Rowe[1], J.A. Kolberg[1], R.N. Bergman[2], L.E. Wagenknecht[3];
[1]Research, Tethys Bioscience, Emeryville, [2]Keck School of Medicine, University of Southern California, Los Angeles, [3]School of Medicine, Wake Forest University, Winston-Salem, USA.

Background and aims: The Insulin Resistance in Atherosclerosis (IRAS) Study demonstrated that insulin sensitivity (SI), acute insulin response (AIR) and the disposition index (DI) as measured by frequently-sampled intravenous glucose tolerance tests (FSIGT) were each predictive of future diabetes in a multi-ethnic population. While such careful measurements of glucose homeostasis provide useful prognostic information, the FSIGT test itself is impractical for standard clinical practice. The PreDx™ Diabetes Risk Score (DRS) is a prognostic test that combines the fasting concentrations of glucose, insulin, hemoglobin A1c, adiponectin, C-reactive protein, ferritin and interleukin-2 receptor alpha into an absolute risk for conversion to diabetes within five years (as defined by the WHO 1999 criteria).
Materials and methods: We measured the DRS in baseline IRAS samples from 722 subjects (including 127 that subsequently converted to diabetes) and evaluated the correlation of the DRS and its individual components with SI, AIR and DI. To further evaluate the relationship of the DRS to insulin sensitivity, insulin secretion or beta cell function, we determined the incremental performance of logistic models combining SI, AIR or DI with the fixed DRS score in predicting incident diabetes.
Results: The DRS was strongly and significantly correlated with both SI ($r = -0.52$, $p < 0.01$) and DI ($r = -0.54$, $p < 0.01$), and weakly correlated with AIR ($r = -0.20$, $p < 0.01$). Additionally, each of the individual components of the DRS except IL-2 receptor alpha correlated significantly with SI and DI. The DRS, SI, AIR and DI were each significant predictors of the onset of diabetes ($p < 0.01$) with C-statistics of 0.75, 0.68, 0.69 and 0.79, respectively. Adding SI to DRS did not significantly improve the prediction of incident diabetes, indicating that the DRS captures the biological basis of SI-induced diabetes. Conversely, adding DRS increased the C-statistics of SI by 0.07 ($p < 0.01$) and AIR by 0.10 ($p < 0.01$), but did not improve the performance of the DI.
Conclusion: The DRS correlates strongly and significantly with SI and the DI. In addition to this correlation the DRS substitutes for, and exceeds, the capacity of SI to predict incident diabetes ($p < 0.01$), and it can be performed from a fasted sample. The DRS represents a simple and practical approach to identifying patients at risk for SI or DI-driven type 2 diabetes.

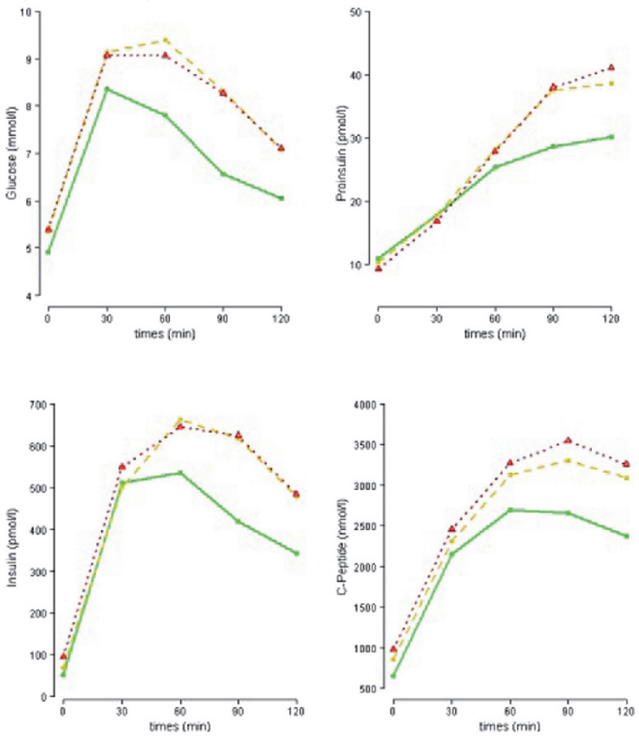
Screening for insulin resistance in persons with increased diabetes risk by EZSCAN

P. Brunswick[1], O. Luis-Dominguez[2], J.-P. Deslypere[3], J.-H. Calvet[1], P. Schwarz[2];
[1]Impeto Medical, Paris, France, [2]Medizinische Fakultät Carl-Gustav Carus, Dresden, Germany, [3]Aesculape Pte Ltd, Singapore, Singapore.

Background and aims: Prevalence of type 2 diabetes and pre-diabetes are increasing globally. Early identification and intervention even in persons with pre-diabetes will reduce/delay progression to diabetes and related complications. There is a lack of simple, fast, reproducible and cheap methods for early diagnosis and screening of people at risk for diabetes. EZSCAN was recently developed to measure sweat gland function through measurement of electro skin conductance (ESC) based on reverse iontophoresis. The aim of the study was to evaluate the ability of EZSCAN to predict insulin resistance in subjects at high risk of diabetes.
Materials and methods: 230 subjects with a family history of type 2 diabetes, obesity or dyslipoproteinaemia from the city of Dresden and adjoining area (37% male, mean age 56.4±13.9yrs, mean BMI 27.8±5.0kg/m2) were involved in the study and had an oral glucose tolerance test (OGTT) with measurement of plasma glucose, pro-insulin, insulin and C-peptide at 0, 30, 60, 90 and 120 minutes. EZSCAN results are given in colour codes based on the values of ESC on feet, hands and forehead: Green - Normal; Yellow - Borderline; Orange-Red - High risk.
Results: Based on ESC values measured by EZSCAN 56 subjects were classified as green, 115 as yellow and 54 as orange-red. Results of glucose, proinsulin, insulin and C-peptide for OGTT according to EZSCAN classification are displayed on Figure. Patients classified as green on EZSCAN had significant lower values for glucose and insulin at 60, 90 and 120 min. and for C-peptide at 90 and 120 min. when compared to patients of yellow or orange-red groups.
Conclusion: EZSCAN is a new simple and non invasive method for identifying subjects at high risk for diabetes.



611

Serum advanced glycation end products is associated with insulin resistance independent of adiponectin

K.C.B. Tan, S.W.M. Shiu, Y. Wong, X. Tam;
Department of Medicine, The University of Hong Kong, Hong Kong.

Background and aims: Recent in vitro experimental data have suggested that advanced glycation end products (AGEs) may play a significant role in the development of insulin resistance by interfering with the molecular pathways of insulin signaling. We have investigated whether the degree of insulin resistance in human subjects is associated with circulating level of AGEs.
Materials and methods: 165 healthy non-diabetic subjects (77 male and 88 female) were recruited from the community. Serum levels of AGEs and adiponectin were measured by ELISA. Insulin resistance was determined by using the homeostasis model assessment index (HOMA-IR).
Results: Serum AGEs was higher in male than female subjects (3.91 ± 1.18 unit/ml vs 3.49 ± 1.22, p=0.03). There was no significant difference in age between male and female subjects but male subjects had higher body mass index (25.5 ± 2.6 kg/m^2 vs 23.6 ± 3.3, p<0.01) and waist circumference (86.4 ± 7.1 cm vs 76.4 ± 8.6, p<0.01). Male subjects were more insulin resistant, HOMA- IR [median 1.37 (interquartile range 0.81 - 2.19) vs 1.12 (0.64 - 1.78), p=0.04] and had lower serum adiponectin level [6.24 ug/ml (3.99 - 8.98) vs 10.67 (7.92 - 15.12), p<0.01]. In both male and female subjects, serum AGEs correlated with HOMA-IR (r=0.37, p< 0.01; r=0.26, p=0.02 respectively). Serum AGEs remained an independent determinant of HOAM-IR even after adjusting for age, gender, waist, smoking and adiponectin level on multiple linear regression analysis.
Conclusion: Formation and accumulation of AGEs progress during normal aging. We have demonstrated that circulating level of AGEs is associated with insulin resistance in non-diabetic subjects independent of adiponectin.

612

Alzheimer's disease in normoglycaemic patients: an association with decreased insulin sensitivity and atherogenic profile of lipid abnormalities

M. Macesic[1], N.M. Lalic[1,2], V.S. Kostic[2], A. Jotic[1], E. Stefanova[2], K. Lalic[1], T. Milicic[1], L. Lukic[1], N. Rajkovic[1], J. Seferovic-Mitrovic[1], S. Aleksic[1];
[1]Institute for endocrinology, [2]Institution for neurology, Belgrade, Serbia.

Background and aims: Previous studies have suggested that insulin resistance might play an important role in pathogenesis of Alzheimer's disease (AD), but the relevant mechanisms of this influence have not yet been clarified. The study was aimed to analyze in patients with AD the levels of (a) insulin sensitivity (IS), (b) plasma insulin (PI) and (c) lipid parameters comprising total cholesterol (Ch), low-density (LDL) and high density (HDL) Ch, triglycerides and apolipoproteins (apoAI, apoAII, apoB, Lp(a) and apoE) potentially involved the pathogenesis of the disease.
Materials and methods: In the study we included 57 normoglycemic patients with AD (group A; BMI: 23,95 +/- 0.81 kg/m2, mean age of 72,34+/-8,60 years) and 25 matched controls (group B; BMI: 25,43 +/- 0,66 kg/m2, mean age of 61,33+/-6,75 years). IS was evaluated by using euglycemic hyperinsulinemic clamp technique with insulin infusion rate of 1 mU/kgbw/min during 120 min and glucose infusion adjusted manually, at 5 min intervals, to maintain target euglycemia. Total glucose uptake (M value) was calculated on the basis of the amount of glucose infused during steady state period (80-120 min). PI levels were determined by radioimmunossay and PG levels by glucose oxidase method. Total cholesterol, HDL-Ch, and triglycerides levels were determined by using enzymatic method, and LDL-Ch was calculated using the formula of Friedewald. Apolipoproteins ApoAI, ApoAII, Lp(a), ApoB and ApoE were determined by using nephelometry method.
Results: We found that total glucose uptake was significantly lower in group A compared to group B (6,41 +/- 0,60 vs 8,13 +/- 0,33 mg/min/kg, p<0.01). In addition, basal PI levels were higher in group A compared to group B (15,57 +/- 2,01 vs 7,34+/-0,98 mU/l, p<0.05), while basal PG levels did not differ between the groups. Moreover, the levels of total Ch and LDL-Ch were significantly higher in group A in comparison to group B (6,47 +/- 0,23 vs 5,71 +/- 0,19; 4,40 +/- 0,19 vs 3,58 +/- 0,17 mmol/l, respectively, p<0.01), while the HDL-Ch levels were significantly lower in group A than in group B (1,21 +/- 0,04 vs 1,48 +/- 0,32 mmol/l, p<0.01). The levels of triglycerides did not differ significantly between the groups (1,58+/- 0,14 vs 1,58 +/- 0,13 mmol/l, p=NS. In addition, the levels of ApoAI were significantly lower in group A in comparison to group B (1,493+/-0,058 vs 2,02+/-0,37 g/l, p<0.01), while the

levels of other apolipoproteins, ApoAII, ApoB, Lp(a) and ApoE did not differ significantly between the groups (330,24+/-10,57 vs 330,37+/-12,07 mg/L; 1,135 +/- 0,056 vs 1,06 +/- 0,28 g/l; 0,264+/-0,053 vs 0,24+/-0,07 g/l; 42,63+/-1,89 vs 40,40+/-1,15 mg/L, respectively, p=NS).
Conclusion: Our results have demonstrated that the presence of AD in normoglycemic patients was associated with decreased IS and increases in peripheral insulin levels. Our results imply that decreased IS levels might exert, at least partly, their pathogenic influence through the lipid abnormalities especially the decreases in HDL-Ch and ApoAI levels.

613

Relationship between insulin resistance and puberty in obese children with increased cardiometabolic risk
B. Tobisch[1], L. Blatniczky[1], L. Barkai[2];
[1]St. John's and North-Buda United Hospitals of Budapest Municipality, Budapest, [2]Postgraduate Institute of Pediatrics, University of Debrecen Medical and Health Science Center, Miskolc, Hungary.

Background and aims: Epidemiolgy data provide evidences that the frequency of obesity and cardiometabolic risk factors shows an increasing tendency in childhood. Insulin resistance playa a central role in the pathogenesis of cardiovascular and metabolic consequences of obesity. Transient decrease in the insulin sensitivity during puberty is a well-known physiological process, however the feature of this phenomenon is not clear in obese children with increased cardiometabolic risk. The aim of present study was to assess the effect of puberty on insulin resistance and metabolic parameters in obese children with and without increased cardiometabolic risk.
Materials and methods: Anthropometry data, insulin levels during OGTT and lipid status were analyzed of 161 obese children aged 10-18 years. Σinsulin/Σglucose ratio obtained during glucose load and HOMA index were used to assess insulin resistance. Children were sorted into prepubertal (T1), pubertal (T2-4) and postpubertal (T5) cohorts according to Tanner staging criteria and metabolic and insulin resistance parameters were evaluated. Increased cardiometabolic risk (CMR) was defined as the presence of any two risk factors (elevated FPG, BP, TG or decreased HDL-C) in addition to obesity.
Results: Out of 161 obese subjects, 43 (26.7%) had CMR. Decreased HDL and/or elevated TG was observed in 92 (57.1%) cases. IGT and/or IFG was found in 25 (15.5%) cases. In subjects without CMR, the Σinsulin/Σglucose ratio in T1 stage was significantly lower than in T2-4 and T5 stages (p=0.01). In children with CMR, the Σinsulin/Σglucose ratio was similar in T1, T2-4 and T5 stages, however it was significantly higher in T1 stage as compared to subjects without CMR (p=0.04). In T2-4 and T5 stages, the Σinsulin/Σglucose ratio did not differ between children with and without CMR. No difference was found in HOMA index between groups with and without CMR in T1 stage, however significantly higher levels were observed in CMR subjects in T2-4 stages (p=0.01), indicating the presence of fasting hyperinsulinaemia in this cohort. Elevated HbA1c (>6.0%) was found in 13 (12.6%) out of 81 children investigated, of whom only two cases had abnormal OGTT results. In cases having normal HbA1c, OGTT showed IGT in 2 cases, IFG in 2 cases IGF and IGT together in 2 cases and T2DM also in 2 cases, respectively.
Conclusion: Increased insulin resistance can be observed in obese children without CMR. In obese children with CMR, substantial insulin resistance occurs in prepuberty and it is present in similar level throughout puberty. Fasting insulin levels are elevated in obese CMR subjects as compared to those without CMR. To reveal T2DM cases, HbA1c and OGTT results should be assessed in parallel.

***In vivo* glucose and amino acid sensitivity to insulin in subjects with impaired glucose regulation**
L.F. Clark[1], M.C. Thivierge[1], S.C. McGeoch[1], P. Abraham[2], D.W.M. Pearson[2], G.E. Lobley[1];
[1]Rowett Institute of Nutrition and Health, University of Aberdeen, [2]Department of Diabetes, Aberdeen Royal Infirmary, United Kingdom.

Background and aims: Insulin is central to control of glycaemia but also regulates tissue protein metabolism including skeletal muscle, a major contributor to post-prandial glucose disposal.
Hypothesis: A dysregulation in insulin sensitivity to glucose will be accompanied by a comparable change in sensitivity of protein metabolism in subjects with impaired glucose regulation (IGR) as has been shown in healthy volunteers by Chevalier et al. This change in insulin sensitivity may occur through suppression of endogenous glucose production (EGP) and protein breakdown and/or altered disposal of glucose and amino acids (AA).
Materials and methods: Twenty-four volunteers (16 men, 8 women; mean age 60.3 years (52-68 years)) with IGR had assessment of basal EGP and whole body protein breakdown determined with stable isotope tracers. This was followed immediately by a 3h hyperinsulinaemic-euglycaemic-euaminoacidaemic clamp (40 mU/m^2/min) to assess insulin sensitivity. During the clamp, suppression of EGP and whole body protein breakdown were determined with the stable isotopes. The relationship between basal metabolic parameters and both glucose and AA disposal with other variables were investigated using regression analyses.
Results: Mean pre-clamp EGP was 2.80mg/kgFFM/min (2.08-4.40 mg/kgFFM/min) with a mean suppression of 78.8% (63.6-98.2%) during the clamp and mean protein breakdown was 5.20 mg/kgFFM/min (4.20-8.06 mg/kgFFM/min) with suppression of 30.1% (15.0-50.7%) during the clamp. Mean disposal of exogenous glucose was 5.63 mg/kgFFM/min (Range: 1.85-13.30 mg/kgFFM/min) and mean disposal of total glucose (exogenous glucose and residual EGP) was 6.12 mg/kgFFM/min (Range: 2.34-14.07 mg/kgFFM/min). Mean disposal of exogenous AA was 1.13 mg/kgFFM/min (Range: 0.49-1.76 mg/kgFFM/min) and mean disposal of total AA (exogenous and non-suppressed protein breakdown) was 4.72mg/kgFFM/min (Range: 3.05-5.94 mg/kgFFM/min). Exogenous glucose disposal (EGD) did not show a strong relationship with exogenous AA disposal (R^2=0.14, NS), nor was there a relationship between total glucose and AA disposal. EGD and total glucose disposal showed inverse relationships with HOMA-IR (R^2=0.38, P=0.008; R^2=0.35, P=0.01), weight (R^2=0.37, P= 0.002; R^2=0.34, P=0.003), 2 hour venous glucose (75g OGTT) (R^2=0.33, P=0.009; R^2=0.32, P=0.004) and fasting insulin (R^2=0.40, P=0.007; R^2=0.37, P=0.009). A relationship was demonstrated between total AA disposal and HOMA-IR (R^2=0.34, P=0.008). AA disposal (total or exogenous) was not related to other variables studied.
Conclusion: The hyperinsulinaemic-euglycaemic clamp is a well recognised tool in the assessment of insulin sensitivity; use of an AA clamp is less common. Pereira et al found that HOMA-IR predicted 44% of the variance in the AA clamp in men with type 2 diabetes. Whilst we found similar results between total AA disposal and HOMA-IR, on direct comparison during the insulin clamp no relationship was seen between AA disposal and glucose disposal. These findings in subjects with IGR contrast with Chevalier et al who found a correlation between glucose and AA disposal during the hyperinsulinaemic-euglycaemic-euaminoacidaemic clamps in healthy volunteers.

Mesenteric fat thickness explains the inconsistent relationships between central obesity and insulin resistance
G.T. Ko[1], W.-Y. So[1], E. Liu[2], R.C.W. Ma[1], R. Ozaki[1], A.P.S. Kong[1], W. Chu[2], J.C.N. Chan[1];
[1]Department of Medicine and Therapeutics, [2]Department of Diagnostic Radiology and Organ Imaging, the Chinese University of Hong Kong, Hong Kong, China.

Background and aims: Waist circumference is a screening tool to identify high risk individuals for insulin resistance. However, some obese subjects are insulin sensitive while some non-obese subjects exhibit features of insulin resistance. We previously reported that mesenteric fat thickness (MFT) measured by ultrasound scan explained most of the variance of cardiometabolic

risks. Here, we hypothesize that MFT may explain the inconsistent relationships between central obesity (CO) and insulin resistance.
Materials and methods: This is a cross-sectional study of MFT by ultrasound on 68 healthy Chinese men (mean age [±SD]: 43.7 ± 7.7 years, median: 44.5 years, range 26-68 years). High MFT was defined as MFT ≥ mean ±1 SD (8.7 + 2.9 = 11.6 mm) and CO as WC ≥85 cm.
Results: In these 68 men, 35 (51.5%) did not have CO (CO-) and 33 (48.5%) had CO (CO+). In the CO+ group, subjects in the top quartile of HOMA-IS had lower MFT, higher adiponectin level and were less likely to have fatty liver than the less insulin-sensitive subjects. In the CO- group, subjects in the top HOMA-IR quartile were more likely to have fatty liver, higher MFT and lower adiponectin level than the less insulin resistant subjects. Stratified by CO and MFT, 7 (21.2%) had (CO+MFT+), 26 (78.8%) had (CO+MFT-), 5 (14.3%) had (CO-MTF+) and 30 (85.7%) had (CO-MTF-). The CO+MF+ (1.31 ± 0.51) and CO-MF+ (1.34 ± 1.55) groups had the highest HOMA-IR followed by the CO+MF- (1.17 ± 0.57) and CO-MFT- (0.79 ± 0.37) groups (p-value for trend = 0.036). On multivariate analysis, the independent predictors for HOMA-IS were age, BMI and MFT.
Conclusion: The heterogeneous relationships between IR and CO are largely attributed to MFT which can be used to identify non-obese but insulin resistant subjects as well as obese but insulin sensitive subjects.

Prevalence, metabolic features and prognosis of metabolically healthy obese Italian individuals: the Cremona Study
G. Perseghin[1,2], G. Lattuada[1,2], G. Calori[1], M. Garancini[3], E. Bosi[1,4], L. Luzi[1,2], G. Ruotolo[1,5], L. Piemonti[1];
[1]Internal Medicine, Instituto Scientifico H San Raffaele, Milano, Italy, [2]Università degli Studi di Milano, Milano, Italy, [3]Instituto Scientifico H San Raffaele, Milano, Italy, [4]Università Vita e Salute, Milano, Italy, [5]Astra Zeneca, Molndal, Sweden.

Background and aims: Some obese individuals have normal insulin sensitivity and appear metabolically healthy. Whether this phenotype is associated with increased all-cause mortality risk is controversial.
Materials and methods: We established all-cause mortality through Regional Health Registry files in 2,074 Caucasian middle-aged (57±11 years), individuals of the population survey carried out in 1990-1991 in Lombardy, Italy (Cremona Study) 15 years after the baseline assessment. Study subjects were divided in four categories based on BMI (non-obese: < 30 kg/m^2; obese; ≥ 30 kg/m^2) and estimated insulin resistance (insulin-sensitive: HOMA-IR < 2.5; insulin-resistant ≥ 2.5).
Results: Data for 2,011 individuals were available. 43 of the 380 obese individuals (11%; 95%CI: 8.1-14.5%) were insulin-sensitive based on HOMA-IR. Their BMI was not different when compared to obese insulin-resistant (32±4 vs 33±3 kg/m^2), but they had lower waist circumference (94±9 vs 104±11 cm; p<0.05), blood pressure, fasting glucose, triglycerides and fibrinogen, and higher HDL-cholesterol. The total number of deaths after 15 years was 495 (CVD: 221, cancer: 180). We found that age, and sex adjusted all-cause mortality was higher in the obese insulin-resistant (HR: 1.40; 95% CI: 1.08-1.81; P=0.01) but not in the metabolically healthy obese (HR: 0.99; 95% CI: 0.46-2.11; P=0.97) when compared to non-obese insulin-sensitive subjects. Also CVD and cancer mortalities were higher in the obese insulin-resistant (HR for CVD: 1.61; 95% CI: 1.10-2.36; P=0.015 and HR for cancer: 1.52; 95% CI: 1.02-2.26; P=0.04, respectively) but not in the metabolically healthy obese (HR for CVD: 0.73; 95% CI: 0.18-3.00; P=0.66 and HR for cancer: 1.04; 95% CI: 0.32-3.30; P=0.95, respectively) when compared to non-obese insulin-sensitive subjects.
Conclusion: The metabolically healthy obese phenotype is less frequent than previously thought and in contrast with the obese insulin resistant subjects, did not show an increased all-cause mortality risk during the 15 years observational period.

Insulin demand, beta cell response and glucose control among contemporary children - an eight-year longitudinal study
T.J. Wilkin, A.N. Jeffery, B.S. Metcalf, J. Hosking, A.E. Fremeaux, L.D. Voss; University Medicine, Derriford Hospital, Plymouth, United Kingdom.

Background and aims: Glucose control becomes impaired when insulin secretion can no longer meet insulin demand. Little is known of their trends over time in contemporary children, for whom obesity, insulin demand and diabetes are rising progressively.
Materials and methods: We plotted the trajectories of fasting glucose and insulin annually over eight years in a single cohort of 258 healthy children (144 boys) and modelled the corresponding beta-cell response from the HOMA2 programme. Analyses were conducted according to exposures at 5y (quartiles of insulin and quartiles of BMI) and outcome at 13y (quartiles of glucose). The children were of uniform age (SD±3m) and race (99% White Caucasian), and were randomly selected at 5y from 54 primary schools.
Results: Mean glucose rose linearly from 4.3 mmol/l at 5y to 5.1 mmol/l at 13y (p<0.001).
Exposures: BMI had no impact on the behaviour of glucose. HOMA-B rose gently from 5-13y among children in the lowest quartile for insulin (panel 1), consistent with a progressive rise in demand, but fell steeply from 5-7y - despite rising glucose - among those in the highest quartile (consistent with a primary loss of beta cell function in those most beta cell stressed). *Outcome:* mean glucose at 13y was considerably higher in Q4 (5.5 mmol/l) than Q1 (4.7 mmol/l, p<0.001), and had been higher throughout (panel 2). Fasting insulin levels, on the other hand, were similar (at 5y Q1 4.10, Q4 3.42 mu/l, p=0.13; at 13y, Q1 6.11, Q4 7.22 mu/l, p=0.16). The difference between Q1 and Q4 children for glucose at 13y lay in HOMA-B (panel 3), which was substantially lower in Q4 than Q1 (83.1% v 102.5% at 13y, p=0.005) Gender, physical activity (accelerometry) and pubertal stage all influenced these trends, but only marginally.
Conclusion: HOMA-B should be interpreted in the context of insulin demand, and the striking difference for children in the highest quartile for glucose at 13y was not their insulin demand at 5y, but their lack of beta cell response to the subsequent rise in insulin demand - consistent with (and possibly explaining) their relatively poorer glucose control.

Insulin resistance and increased PAI-1 as factors of non-alcoholic fat liver disease in children, adolescents and youth metabolic syndrome

V.S. Dimitrijevic-Sreckovic[1], B.M. Sreckovic[2], P.B. Djordjevic[1], D.M. Gostiljac[1], M. Civcic[1], I. Soldatovic[3], H.S. Petrovic[1];
[1]Diabetology, Institute of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, [2]Cardiology, Clinical Center Bezanijska Kosa, [3]Statistics, Institute for Medical Statistics and Informatics, Clinical Center of Serbia, Belgrade, Serbia.

Background and aims: In metabolic syndrome (MS) patients, abdominal obesity accompanied with hyperinsulinism and insulin resistance is related to hypertension and lipid status disturbance where thrombotic and inflammatory factors and low antioxidant status and tendency to early atherosclerosis are present. Hepatic fat accumulation in childhood obesity is associated with increased visceral fat and insulin resistance (IR). IR results in fat deposition in the liver and occurrence of non-alcoholic fat liver disease (NAFLD). The study was aiming at determining NAFLD and its most important provoking factors in MS and pre-metabolic (pre-MS) syndrome patients.
Materials and methods: The study included 173 obese individuals aged 7 to 30 classified into 3 groups: I-children (7-15), II-adolescents (16-20) and III-youth (20-30). Three of the following five criteria were used for metabolic syndrome (MS) diagnosis in adolescents: waist circumference >90Pct; triglycerides >1.7mmol/l; HDL-cholesterol<1.0mmol/l; hypertension>90Pct, glycemia >6.0mmol/L. ATP III classification was applied for youth. Patients with less than three afore mentioned criteria were considered patients with pre-MS. OGTT was used to evaluate the extent of disorder. Insulin sensitivity was determined by HOMA IR. PAI-1 was determined by plasminogen substrate assay**.** SGOT, SGPT and γ-GT were considered liver function parameters. Liver ultrasonography was used to diagnose NAFLD.
Results: NAFLD, increasing considerably with age, was found in 7.3% children, 18.9% adolescents and 29.0% youth (p<0.05). NAFLD existed in 17.5% pre-MS and 29.0% MS patients. NAFLD found by groups: pre-MS patients - I-11.5%, II-17.7%, III-20.4%; MS patients - II-20.4%, III-40.0%. Logistic regression analysis indicated the most important NAFLD factors: body weight - odds ratio (OR) 1.039, p<0.001; LDL-cholesterol OR 1.55, p<0.05; creatinine clearance OR 1.01, p<0.05; uric acid OR 1.00, p<0.05; insulins - 0min OR 1.012, p<0.002, 120min OR 1.008, p<0.001; HOMA IR OR 1.059, p<0.001; PAI-l OR 2.79, p<0.001; SGPT OR 1.27, p<0.001. Patients with NAFLD had increased WC (110.7±11.9cm), LDL-cholesterol (3.3±1.0mmol/l), triglycerides (1.81±1.15mmol/l), uric acid (383.8±86.3), insulins 0min (61.1±81.3U/l) and 120min (93.1±108.4U/l), HOMA IR (14.7±4.4±19.3μmol/mU/ml), PAI-1 (7.3±0.6U/ml), SGPT (56.7±20.9U/l), γ-GT (44.1±22.8U/l). Patients without NAFLD had normal SGPT, γ-GT, uric acid and increased WC (98.6±16.7cm), insulins 0min (21.6±31.3U/l) and 120 min (44.3±49.5U/l), HOMA IR (6.2±3.4μmol/mU/ml), triglycerides (1.74±1,63mmo/l), PAI-1 (6.0±1.4U/ml) but lower than NAFLD patients.
Conclusion: Obesity, hyperinsulinemia with IR (characterized by increased uric acid and PAI-1), SGOT and LDL-cholesterol are the most frequent risk factors for NAFLD. NAFDL may be the liver sign of pre-MS and MS children, adolescents and youth associated with visceral obesity, IR, lipid status disturbance, thrombotic and inflammatory factors.

619

Steatohepatitis is closely associated with insulin resistance and the metabolic syndrome from early stages of their development

Y. Mori[1], K. Ura[2], K. Matsuura[1], Y. Itoh[1], J. Yokoyama[1], N. Tajima[1];
[1]Department of Internal Medicine, Jikei University School of Medicine, Tokyo, [2]Department of Internal Medicine, Utsunomiya Memorial Hospital, Utsunomiya, Japan.

Background and aims: Non-alcoholic fatty liver disease (NFALD), insulin resistance, and the metabolic syndrome were examined for correlation in individuals undergoing elaborate health checkup programs with the influence of abdominal obesity being ruled out.
Materials and methods: Of the 909 subjects undergoing the health checkups, 626 individuals who underwent a 75 g OGTT and were evaluated by abdominal ultrasound for fatty liver and the metabolic syndrome were enrolled in the study, and 130 individuals each with fatty liver (fatty liver group; FLG) and without fatty liver (non-fatty liver group; NFLG), who were matched for gender, age, BMI, and waist circumference, were compared for relevant biochemical parameters, insulin resistance, number of risk factors implicated per individual, and frequency of the metabolic syndrome detected.
Results: There was no significant difference between the FLG and the NFLG in the male to female ratio (%), age, BMI (24.8 ± 2.9 and 24.2 ± 1.8, respectively), and waist circumference (85.8 ± 6.6 and 84.5 ± 5.8, respectively). In contrast, significantly higher values were noted in the FLG than in the NFLG with regard to the area under the glucose curve at 75 g OGTT (363.0 ± 81.3 versus 319.0 ± 70.6; $P < 0.001$), area under the insulin curve (109.0 ± 80.4 versus 76.1 ± 45.1; $P < 0.001$), HOMA-R index (1.73 ± 1.24 versus 1.17 ± 0.56; $P < 0.001$), HbA1c, AST, ALT, TG, and LDL-C, while HDL-C was significantly lower in the FLG than in the NFLG. Additionally, significantly higher values were noted in the FLG than in the NFLG with regard to the number of risk factors implicated per individual (1.83 ± 1.15 versus 1.37 ± 1.09; $P < 0.001$), frequency of the metabolic syndrome detected (30/130, 23.1% versus 14/130, 10.8%; $P < 0.05$).
Conclusion: Study results suggested that NAFLD is closely associated with insulin resistance and the metabolic syndrome even when the influence of abdominal obesity is excluded. It was further suggested that, given the BMI of < 25 kg/m^2 and the waist circumference of no more than 85 cm in the subjects, NAFLD appears to be implicated in the pathogenesis of insulin resistance and the metabolic syndrome from quite early stages of their development.

620

Distinctive metabolic signature in subjects with early onset type 2 diabetes

K. Wanic[1], A. Pazderska[1], S. Shah[1], D. O'Hanlon[1], J.R. Bain[2], R.D. Stevens[2], C.B. Newgard[2], J.J. Nolan[1];
[1]St. James's Hospital, Trinity College Dublin, Metabolic Research Unit, Ireland, [2]Duke University, Durham, USA.

Subjects with early onset type 2 diabetes have severe insulin resistance, reduced VO_2 max response to exercise, and abnormal mitochondrial function relative to equally obese insulin resistant control subjects. Having previously used a metabolomics approach to demonstrate that obese insulin resistant subjects have a distinct metabolic profile compared to lean controls, we have now studied subjects with early-onset type 2 diabetes. We used targeted MS/MS and GC/MS-based metabolomics to measure fasting plasma concentrations of amino acids and total and free fatty acids in 24 subjects with early onset type 2 diabetes (mean age 26.1, BMI 35.6 kg/m2), 17 obese controls (mean age 22.8, BMI 34.2 kg/m2) and 28 lean controls (mean age 24.7, BMI 22.4 kg/m2). Confirming previous studies, the obese subjects had increased levels of branched-chain and other amino acids, total non-esterified fatty acids (NEFA), and several individual fatty acid species compared to lean controls. Interestingly, subjects with type 2 diabetes exhibited additional increases in levels of valine, leucine/isoleucine, glutamate/glutamine, and aspartate/asparagine, as well as NEFA and individual fatty acids compared to obese controls. Insulin resistance, measured by HOMA-IR correlated with concentrations of valine, leucine, histidine and glutamate.

Parameter studied (μM)	Early onset type 2	Obese controls	Lean controls	P value (1 vs. 2)	P value (1 vs. 3)
L-valine	298	261	214	0.031	<0.001
L-leucine/isoleucine	206	170	151	0.004	<0.001
L-aspartic acid/aspargine	103	78	70	0.009	<0.001

We conclude that subjects with early-onset type 2 diabetes have a metabolomic profile distinguishing them from BMI-matched insulin resistant individuals with normal glucose tolerance. Further studies are needed to assess whether these changes are a reflection of altered mitochondrial function in these subjects.

Insulin resistance is associated with metabolic syndrome but not with angiographically determined coronary artery disease in female patients

A. Vonbank[1,2], C.H. Saely[1,2], P. Rein[1,2], S. Beer[1,2], C. Boehnel[1,2], V. Jankovic[1,2], H. Drexel[1,2];
[1]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [2]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Insulin resistance (IR) is the key feature of the metabolic syndrome (MetS) and in prospective studies predicts atherothrombotic events. Its association with directly visualised coronary atherosclerosis, especially in female patients, is unclear. We hypothesised that IR is associated with both angiographically determined coronary artery disease (CAD) and with the MetS.
Material and methods: We enrolled 354 consecutive female patients undergoing coronary angiography for the evaluation of suspected or established stable CAD; significant CAD was diagnosed in the presence of significant coronary stenoses with lumen narrowing ≥50%. IR was determined by the HOMA index; the MetS was defined according to ATPIII criteria.
Results: HOMA-IR scores were significantly higher in MetS female patients than in female subjects without the MetS (4.9 ± 4.7 vs. 1.9 ± 1.1; p <0.001). In contrast HOMA-IR did not differ significantly between patients with significant CAD and those who did not have significant CAD 3.3 ± 3 vs. 3.1 ± 3; p = 0.823). When both, the presence of MetS and of significant CAD were considered, HOMA-IR was significantly higher in patients with the MetS both among those who had significant CAD (4.9 ± 4.8 vs. 1.9 ± 1.1; p <0.001) and among those who did not have significant CAD (5.0 ± 4.7 vs. 1.9 ± 1.1; p <0.001) whereas it did not differ significantly between patients with significant CAD and subjects without significant CAD in patients with the MetS (5.0 ± 4.7 vs. 4.9 ± 4.8; p = 0.383) nor in those without MetS (1.9 ± 1.1 vs. 1.9 ± 1.0; p = 0.860). Similar results were obtained with the IDF definition of the metabolic syndrome.
Conclusion: In female patients IR is significantly associated with the MetS but not with angiographically determined coronary atherosclerosis.

Obstructive sleep apnoea and metabolic abnormalities in type 2 diabetes

S.K. Wangnoo[1], M.A. Siddiqui[1], M. Gupta[1], M.S. Kanwar[2];
[1]Endocrinology, [2]Pulmonary Medicine, Apollo Hospital, New Delhi, India.

Background and aims: The burgeoning load of type 2 diabetes is a major public health concern in our part of the world with high morbidity, mortality, and health-care costs. Recent reports have indicated that the majority of patients with type 2 diabetes also have obstructive sleep apnea (OSA). There is compelling evidence that OSA is a significant risk factor for cardiovascular disease and mortality. Because both diabetes and OSA are associated with increased cardiovascular morbidity and mortality, it is possible that the presence of both conditions results in additive or even synergistic health risks. The aim of this study was to evaluate the prevalence of OSA in the study population and its effect on the metabolic profile.
Materials and methods: After taking the informed consent of the subjects, we performed polysomnography studies in 30 consecutive patients with diabetes and obesity according to the Asian-Indian criteria recruited from outpatient clinics between July 2009 and January 2010. Apnoea- hypopnoea index (AHI) > or = 10/hour was considered relevant for OSA diagnosis. Subjects with AHI< 10 were considered as controls. We assessed AHI, Epworth sleepiness scale (ESS), body mass index (BMI, kg/m^2), glycosylated haemoglobin (HbA1c, %), fasting serum total cholesterol (mg%), HDL-(mg%), LDL-cholesterol(mg%), triglycerides (TG) (mg%), HOMA index and highly sensitive C-reactive protein (hsCRP, mg/l).
Results: Data are presented as mean +/- SD or median (interquartile range) for parametric and nonparametric data respectively. 22 out of 30 subjects (73%) of with diabetes had OSA (AHI > or =10). AHI in the OSA group was 21 (16-30) and 5 (3-8) in controls (p < 0.001). BMI was higher in OSA (33.8 +/- 5.8) vs. controls (29.4 +/- 3.1) (p = NS). Patients with OSA had higher HbA1c (9.72 +/- 0.9) vs. (8.94 +/- 0.8)(p = 0.03), TG (210 +/- 55.2) vs. (140.2 +/- 41.9) (p = 0.046), HOMA-IR (2.35 +/- 1.6) vs. (1.93 +/- 1.5)(p = 0.046) and hsCRP (4.2 +/- 0.9) vs. (2.89 +/- 1.4)(p = 0.01). HDL-cholesterol was lower in OSA group compared to control (30.8 +/- 6.1 vs. 40.3 +/- 11.4) (p = 0.02). HbA1c correlated best with AHI(p < 0.001, r = 0.39).
Conclusion: Identifying the possibility of previously unrecognized OSA amongst patients with diabetes is important for treating physicians even in the absence of specific symptoms. The high prevalence of OSA in obese patients with type 2 diabetes is also associated with more severe metabolic derangements and its treatment along with adjustment of antidiabetic therapy may ameliorate some of the associated morbidity and mortality.

High dietary fat consumption decreases hepatic glucokinase activity and net hepatic glucose uptake in the absence of impaired insulin signalling in dogs

K.C. Coate, G. Kraft, B. Farmer, M. Smith, M. Shiota, A.D. Cherrington;
Molecular Physiology and Biophysics, Vanderbilt University, Nashville, USA.

Background and aims: High dietary fat consumption has been associated with a reduction in insulin's ability to suppress hepatic glucose production during euglycemia, but its impact on net hepatic glucose uptake (NHGU) and disposition during hyperglycemia (HG) has not been determined. The purpose of the present study was to elucidate the effect of high fat feeding on the ability of the liver to take up glucose in the presence of hyperinsulinemia (HI), HG and the portal glucose signal (PS).
Materials and methods: Adult male dogs were fed either a high fat diet (HFD, % kcal: 53% fat, 21% protein, 26% carbohydrate; *n*=4) or a chow control diet (CTR, % kcal: 26% fat, 31% protein, 43% carbohydrate; *n*=5) for 4 weeks. Dogs underwent hepatic/portal vein catheterization at 2 weeks and an HIHG clamp 2 weeks later. Somatostatin was infused peripherally (Pe) to disable the endocrine pancreas while glucagon (basal) and insulin (4x basal) were replaced intraportally (Po). The glucose load to the liver was doubled first by infusing glucose Pe (Period 1; P1), then by infusing glucose Po (PS; 22.2 μmol/kg/min) and Pe (Period 2; P2).
Results: When challenged with HI and HG (P1), NHGU (μmol/kg/min) was significantly lower in the HFD group (0.0±0.0.5) compared to the CTR group (9.4±1.1, $P<0.01$). Consistent with this finding, glycogen synthesis (μmol/kg/min; HFD: -1.4±0.3 [breakdown], CTR: 4.0±1.7, $P<0.01$) and net hepatic lactate output (μmol/kg/min; HFD: 2.9±0.4, CTR: 6.8±0.9, $P<0.01$) were also significantly lower in the HFD group compared to the CTR group. On the other hand, Po glucose delivery (PS; P2), elicited a comparable increase in NHGU (ΔP1-P2, μmol/kg/min; HFD: 8.2±1.7, CTR: 9.0±2.6, $P=0.7$) and glycogen synthesis (ΔP1-P2, μmol/kg/min; HFD: 9.0±2.7, CTR: 10.9±2.5, $P=0.8$) in both groups, suggesting that the portal glucose signal was still effective in the HFD group. Terminal liver biopsies revealed a reduction (≈20%) in glucokinase (GK) total protein content coincident with a significant decrease (≈48%, $P<0.01$) in GK activity (U/g liver) in the HFD group (2.3±0.4) compared to the CTR group (4.4±0.5). Surprisingly, the decrease in GK protein was not the consequence of attenuation in insulin signal transduction given that phosphorylation of IRS1-Y1222 and Akt-S473 was similar between the HFD and CTR groups.
Conclusion: Four weeks of HFD consumption impaired the effect of hyperinsulinemia and hyperglycemia on NHGU and glycogen synthesis; however, it did not alter the response of either to the portal glucose signal. Although the HFD was associated with a decrease in hepatic GK activity, this was not due to a reduction in the activation of either IRS1 or Akt. These data suggest that alternative control mechanisms are involved in the regulation of hepatic GK, and these may have a significant impact on the ability of the liver to take up glucose.

Hepatic glycogen supercompensation reduces glycogen synthesis without altering net hepatic glucose uptake in dogs

J.J. Winnick, Z. An, M. Smith, W. Snead, A.D. Cherrington;
Molecular Physiology & Biophysics, Vanderbilt University, Nashville, USA.

Background and aims: A hallmark characteristic of diabetes mellitus is glucose intolerance, which is manifest by postprandial hyperglycemia. Because one-third of an oral glucose load is taken up and metabolized by the liver, efforts are underway by pharmaceutical companies to create medications that would increase liver glucose uptake and glycogen synthesis during the postprandial state. While both hyperinsulinemia and portal vein glucose infusion have been shown to stimulate hepatic glucose uptake, little is known about how an increase in the hepatic glycogen content could affect the responses of the liver to these stimuli. Thus, the purpose of this study was to determine how an acute increase in hepatic glycogen affects the liver's ability to take up and metabolize glucose in response to hyperglycemic/hyperinsulinemia or portal glucose infusion.
Materials and methods: During the first 4h of each study, all dogs received somatostatin and basal amounts of intraportal insulin and glucagon. Blood glucose was doubled by glucose infusion into a peripheral vein and either saline (SAL; n=13) or fructose (5.5 μmol/kg/min; FRU; n=13) was infused intraportally; the latter to trigger liver glycogen loading. The glycogen loading period was followed by a 2h control period, during which basal replacement of hormones was continued but fructose was not infused. A 2h experimental period followed, during which hyperglycemia was maintained. One subset of animals from each group received 4x basal insulin (SAL-INS; n=7 and FRU-INS; n=6) while another received an intraportal glucose infusion (22 μmol/kg/min; SAL-PG; n=6 and FRU-PG; n=7) to assess the effect of the hepatic glycogen content on net hepatic glucose uptake (NHGU) and disposition.
Results: Fructose infusion led to marked differences in hepatic glycogen (345±17 and 538±24 μmol/g liver in SAL and FRU, respectively). The large difference in glycogen had no effect on NHGU (μmol/kg/min) seen in response to hyperinsulinemia (16±4 and 15±4 in SAL-INS and FRU-INS, respectively) or portal vein glucose infusion (19±2 and 17±2 in SAL-PG and FRU-PG, respectively). On the other hand, the percentage of NHGU that was directed to glycogen was reduced ($p<0.04$) by hepatic glycogen supercompensation during hyperinsulinemia (70±3 and 58±10% in SAL-INS and FRU-INS, respectively) and during portal vein glucose infusion (70±6 and 54±3% in SAL-PG and FRU-PG, respectively). Furthermore, these reductions in glycogen synthesis were accounted for primarily by an increase in liver lactate output ($p<0.05$) during both hyperinsulinemia (16±3 and 33±8% in SAL-INS and FRU-INS, respectively) and in response to portal vein glucose infusion (27±6 and 38±4% in SAL-PG and FRU-PG, respectively).
Conclusion: Our data show that acutely increasing the glycogen level from ~350 to ~540 μmol/g had no observable effect upon NHGU, although it caused a reduction in hepatic glycogen synthesis and a compensatory increase in lactate output. Since the reduction in glycogen synthesis seen in response to hyperinsulinemia vs. portal vein glucose infusion were similar, altered activity of glycogenic enzymes are likely responsible for the diminished glycogen synthesis associated with glycogen supercompensation. Thus, as medications are developed to increase postprandial hepatic glucose disposal it should be remembered that although high glycogen levels will not inhibit NHGU, they will increase carbon flux through non-glycogenic pathways.

Per2 plays a major role in the control of liver glycogen metabolism and fasting glycaemia

F. Zani[1], B. Becattini[1], A. Provenzani[2], A. Stauffer[3], J.-P. Montani[1], U. Albrecht[3], G. Solinas[1];
[1]physiology, university of Fribourg, Switzerland, [2]University of Trento, Italy, [3]Biochemistry, University of Fribourg, Switzerland.

Background and aims: Recent evidence suggests that obesity-induced derangements of the expression of molecular components of the circadian clock may be implicated in the development of glucose intolerance. The aim of this study was to investigate the role of the clock protein period 2 (Per2), a key component of the circadian clock whose expression is deranged during obesity, in glucose homeostasis in lean and obese mice.
Materials and methods: To investigate the role of Per2 in glucose metabolism in-vivo we used mice bearing a targeted gene mutation in the Per2 gene (Per2brdm) and thus unable to express a functional Per2 protein. Mice were hosted in our standard mouse facility in a 12-hour light and 12-hour dark cycle. Wt and Per2brdm mice were fed with either standard chow diet or high-fat diet for 24 weeks and analyzed for glucose homeostasis. Glucose tolerance test (GTT) and insulin tolerance test (ITT) were performed on mice food deprived for 7 hours. For pyruvate tolerance test (PTT) mice were fasted for 14 hours. Glucose levels were measured over 12 hours starvation timecourses during the light and the dark phase. Fed and fasting blood glucose and hepatic glycogen content were measured over different circadian timepoints. To investigate the role of Per2 in the control of liver gene expression we performed DNA-microarray analysis of RNA preparations from liver of Per2brdm and WT mice. Results were validated by QPCR.
Results: Our results suggest that Per2 loss of function is not a basic requirement for the development of obesity-induced insulin resistance. Per2brdm mice show similar glucose tolerance compared to WT mice when placed on chow diet, and Per2 loss of function does not predispose to high-fat diet-induced insulin resistance. However, we have identified an important role for Per2 in the control of fasting glycemia and hepatic glycogen metabolism. Per2brdm mice show a decreased fasting glycemia compared to WT controls

during the light phase. This difference is observed after 4 hours of food deprivation, is maximal at 7-8 hours of starvation, and disappears after about 12 hours of starvation. Gene expression-signature analysis from the microarray data indicates decreased expression of genes involved in gluconeogenesis and glycogen metabolism in livers from Per2brdm mice compared to livers from WT mice. PTT was performed to evaluate whole body gluconeogenesis. The results show that WT and Per2brdm mice display similar gluconeogenic potential in a PTT test. To evaluate the role of Per2 in glycogen metabolism we measured hepatic glycogen content in fed or 8 hours fasted WT and Per2brdm mice. The results show that fed Per2brdm mice display lower liver glycogen content during the light phase compared to WT controls. This difference is more pronounced in mice that were starved for 8 hours with Per2brdm mice displaying less than a third of the hepatic glycogen content compared to control WT mice (p-value < 0.005).
Conclusion: Our data suggest that Per2 loss of function is not a major cause or a predisposition factor to impaired glucose tolerance. Nonetheless our results suggest that Per2 plays an important role in the control of fasting glycemia and in hepatic glycogen metabolism.

Evidence for a key role of hepatic mitochondrial phosphoenolpyruvate carboxykinase in glucose homeostasis *in vivo*
R. Stark[1], C.N. Feriod[1], X. Zhao[1], J. Dong[1], S. Bhanot[2], M. Roden[3], G.I. Shulman[1], R.G. Kibbey[1];
[1]Internal Medicine/Endocrinology, Yale University School of Medicine, New Haven, USA, [2]Internal Medicine/Endocrinology, Isis Pharmaceuticals, Carlsbad, USA, [3]German Diabetes Center, Dusseldorf, Germany.

Background and aims: The cytosolic isoform of phosphoenolpyruvate carboxykinase (PEPCK-C) is generally regarded as the primary enzyme that provides PEP for gluconeogenesis and glyceroneogenesis. The metabolic role of the mitochondrial isoform, PEPCK-M, however, has not been established. In contrast to PEPCK-C whose transcription is strongly inhibited by insulin, we hypothesized that the constitutively expressed PEPCK-M isoform, might instead be regulated in response to fuel supply by mitochondrial GTP- a known sensor of mitochondrial metabolic flux in the pancreatic beta-cells.
Materials and methods: To assess its role, PEPCK-M was silenced using siRNA in primary rat hepatocytes and *in vivo* with antisense oligonucleotides in young, weight-matched Sprague Dawley rats. Gluconeogenesis rates in hepatocytes were assessed using ^{13}C-labeled substrates with analysis by mass spectroscopy. Live awake rats were studied by euglycemic hyperinsulinemic clamps and a 36-hour fast.
Results: An 80% reduction of PEPCK-M mRNA in hepatocytes reduced gluconeogenesis by 60% (P<0.001). Similar reductions in gluconeogenesis with PEPCK-M silencing were observed regardless of the presence of glucose, glucagon, or insulin. PEPCK-M message was silenced 80% in liver and the plasma glucose was significantly reduced in fed rats (160±4 vs. 146±5 mg/dl, P<0.05) but was equivalent following a 36 hour fast (115±2 vs. 116±2 mg/dl, P=0.88). Similarly, fed insulin was reduced (57±6 vs. 35±6, P<0.02) but not with fasting (19±3 vs. 18±6 μU/ml, P=0.87). Euglycemic hyperinsulinemic clamps identified significantly increased insulin sensitivity when PEPCK-M was silenced (GINF: 20±1 vs. 26±1 mg/kg/min, P=0.003) that could not be accounted for by differences in endogenous glucose production nor uptake in the muscle or adipose. Interestingly, post-absorptive hepatic glycogen was 82% lower and plasma triglycerides 42% lower along with a 25% reduction in WAT suggesting a constitutive defect in PEP production.
Conclusion: These data from silenced PEPCK-M both in primary hepatocytes and *in vivo* support an important role for PEPCK-M in glucose homeostasis via gluconeogenesis and possibly glyceroneogenesis. Because of the beneficial effects of lowering glucose, insulin, triglycerides and fat mass with a concomitant increase in insulin sensitivity but without hypoglycemia following a prolonged fast, PEPCK-M may be an attractive target for the treatment of type-2 diabetes.

Farnesoid X Receptor inhibits glucose-induced LPK gene expression by interfering with Carbohydrate Response Element Binding Protein (ChERBP) activity
C. Huaman, S. Caron, H. Dehondt, F. Lien, O. Briand, P. Lefebvre, B. Staels; Inserm u1011, Récepteurs Nucléaires, Maladies Cardiovasculaires et Diabète, Lille, France.

Background and aims: Carbohydrate response element binding protein (ChREBP) is a transcription factor which can be activated in response to glucose to induce the expression of the glycolytic gene Liver Pyruvate Kinase (LPK) as well as some lipogenic genes such as Fatty Acid Synthase (FAS) and Acetyl CoA Carboxylase (ACC1). Previous works in our team have shown that the activation of nuclear receptor FXR (Farnesoid X Receptor) inhibits the glucose-mediated induction of these genes. Our aim is to unravel the molecular mechanisms undergoing the negative effect of FXR on the expression of glycolytic and lipogenic genes.
Materials and methods: Two human hepatocyte cell lines, IHH and HepaRG, were treated with different glucose concentrations and with FXR agonist GW4064. Real-time PCR experiments were performed to analyse the expression of the LPK gene. Western blot analysis was used to study the nuclear localisation of ChREBP. Chromatine immunoprecipitation (ChIP) experiments were performed to follow the binding of ChREBP and FXR to the LPK promoter under different experimental conditions.
